Arsenic, white, powdered	lb.	06½ – 07	07¼ – 07½
Arsenic, red, powdered	lb.	12 – 12½	12½ – 13
Barium chloride	ton	108 00 – 110 00	111 00 – 115 00
Barium dioxide (peroxide)	lb.	20 – 21	21½ – 22
Barium nitrate	lb.	06½ – 07	07½ – 08½
Barium sulphate (precip.) (blanc fixe)	lb.	03¾ – 04	04¼ – 04½
Blanc fixe, dry	lb.	04 – 04½	
Blanc fixe, pulp	ton	45 00 – 55 00	
Bleaching powder	100 lb.	1 60 – 1 75	1 80 – 2 75
Blue vitriol (see copper sulphate)			
Borax	lb.	05½ – 05¾	06 – 06¾
Brimstone (see sulphur, roll)			
Bromine	lb.	27 – 28	28½ – 35
Calcium acetate	100 lbs.	1 75 – 2 00	
Calcium carbide	lb.	04½ – 04¾	05 – 05½
Calcium chloride, fused, lump	ton	24 00 – 24 50	24 75 – 27 00
Calcium chloride, granulated	lb.	01½ – 01¾	02 – 02¼
Calcium peroxide	lb.		1 40 – 1 50
Calcium phosphate, tribasic	lb.		15 – 16
Camphor	lb.		80 – 82
Carbon bisulphide	lb.	06 – 06½	06¾ – 07½
Carbon tetrachloride, drums	lb.	09½ – 10	10½ – 12
Carbonyl chloride, (phosgene)	lb.		60 – 75
Caustic potash (see potassium hydroxide)			
Caustic soda (see sodium hydroxide)			
Chalk, precip.—domestic, light	lb.	04¼ – 04½	
Chalk, precip.—domestic, heavy	lb.	03½ – 03¾	
Chalk, precip.—imported, light	lb.	04½ – 05	
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	05 – 05½	05¾ – 06
Chloroform	lb.		37 – 40
Cobalt oxide	lb.		2 00 – 2 10
Copperas	ton	15 00 – 16 00	16 50 – 30 00
Copper carbonate, green precipitate	lb.	19 – 20	20½ – 21
Copper cyanide	lb.		58 – 60
Copper sulphate, crystals	100 lb.	5 50 – 5 60	5 65 – 6 15
Cream of tartar	lb.		24 – 26
Epsom salt (see magnesium sulphate)			
Ethyl acetate com. 85%	gal.		60 – 65
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.		90 – 95
Formaldehyde, 40 per cent	lb.	08½ – 09	09½ – 10
Fullers earth, f.o.b. mines	net ton	16 00 – 17 00	
Fullers earth—imported powdered—net	ton	30 00 – 32 00	
Fusel oil, ref.	gal.		2 15 – 2 50
Fusel oil, crude	gal.		1 30 – 1 50
Glauber's salt (see sodium sulphate)			
Glycerine, c. p. drums extra	lb.		15 – 15½
Iodine, resublimed	lb.		4 05 – 4 15
Iron oxide, red	lb.		12 – 18
Lead acetate	lb.		09½ – 12
Lead arsenate, powd	lb.	14 – 14½	14½ – 15½
Lead nitrate	lb.		15 – 20
Litharge	lb.	07½ – 07¾	08 – 08½
Magnesium carbonate, technical	lb.	06 – 06½	06½ – 08
Magnesium sulphate, U. S. P.	100 lb.	2 50 – 2 60	2 65 – 2 85
Magnesium sulphate, technical	100 lb.		1 60 – 1 80
Methanol, 95%	gal.		57 – 58
Methanol, 97%	gal.		59 – 60
Nickel salt, double	lb.		11 – 11½
Nickel salt, single	lb.		11 – 11½
Phosgene (see carbonyl chloride)			
Phosphorus, red	lb.	45 – 46	47 – 50
Phosphorus, yellow	lb.		30 – 35

		Carlots	Less Carlots
Potassium bichromate	lb.	.10⅛ – .10¼	10½ – 13
Potassium bromide, granular	lb.	..... –	.17 – 20
Potassium carbonate, U. S. P.	lb.	.12 – .12½	.13 – 16
P tassium carbonate, 80–85%	lb.	.05 – .05¼	.05½ – .06
P tassiu n chlorate, crystals	lb.	.06¼ – .06½	.06 – .08
Potassium cyanide	lb.	..... –	.42 – .45
Potassium hydroxide (caustic p tash)	100 lb.	6.00 – 6.10	6.25 – 7.00
Potassium iodide	lb.	..... –	3.10 – 3.15
Potassium nitrate	lb.	.07⅜ – .07½	.08 – .09
Potassium permanganate	lb.	.15 – .15½	.16 – .22
Potassium prussiate, red	lb.	nominal	nominal
P tassium prussiate, yellow	lb.	28½ – .29	.29¼ – .29½
Rochelle salts (see sodium potas tartrate)	....	..... –	..... – ....
Salammoniac, white, granular	lb.	.07 – .07½	.07½ – .08
Salammoniac, gray, granular	lb.	.07½ – .07⅝	.08 – .08¼
Salsoda	100 lb.	1.40 – 1.45	1.50 – 1.80
Salt cake (bulk)	ton	18.00 – 20.00	..... – ....
Soda ash, light	100 lb.	1.80 – 2.00	2.05 – 2.60
Soda ash, dense	100 lb.	1.85 – 1.95	2.00 – 2.50
Sodium acetate	lb.	.04¼ – .04½	.04¾ – .05
Sodium bicarbonate	100 lb.	1.80 – 1.90	1.95 – 2.40
Sodium bichromate	lb.	.07½ – .07⅝	.08 – .08¼
Sodium bisulphate (nitre cake)	ton	4.50 – 4.60	4.65 – 5.50
Sodium bisulphite powdered, U.S.P.	lb.	.04¼ – .04½	.04⅝ – .05¼
Sodium chlorate	lb.	.06½ – .07	.07¼ – .07¾
Sodium chloride	long ton	12.00 – 13.00	..... – .....
Sodium cyanide	lb.	.22 – .23	.23½ – .25
Sodium fluoride	lb.	.09½ – .10	.10¼ – .10½
Sodium hydroxide (caustic soda)	100 lb.	3.70 – 3.75	3.80 – 4.25
Sodium hyposulphite	lb.	.03 – .03¼	.03½ – .03⅝
Sodium nitrite	lb.	.08¾ – .09	.09¼ – .09½
Sodium peroxide, powdered	lb.	.28 – .30	.31 – .35
Sodium phosphate, dibasic	lb.	.03¼ – .04	.04¼ – .04½
Sodium potassium tartrate (Rochelle salts)	lb.	..... –	.18 – .21
Sodium prussiate, yellow	lb.	.17½ – .17¾	.18 – .18½
Sodium silicate, solution (40 deg.)	100 lb.	1.00 – 1.15	1.20 – 1.50
Sodium silicate, solution (60 deg.)	100 lb.	2.35 – 2.50	2.55 – 2.90
Sodium sulphate,crystals(glaubers salt)	100 lbs.	1.00 – 1.15	1.20 – 1.50
Sodium sulphide,fused,60-62 per cent(conc.)	lb.	.04⅜ – .04½	.04 – .05½
Sodium sulphite, crystals	lb.	.03½ – .03⅝	.03¾ – .04¼
Strontium nitrate, powdered	lb.	.09½ – .10	.10½ – .12
Sulphur chloride, yellow	lb.	.04½ – .05	.05¼ – .06
Sulphur, crude	ton	18.00 – 20.00	..... – ....
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.	..... –	2.25 – 3.10
Sulphur, roll (brimstone)	100 lb.	..... –	2.00 – 2.75
Talc—imported	ton	30.00 – 40.00	..... – .....
Ta'c—domestic powdered	ton	18.00 – 25.00	..... – .....
Tin bichloride	lb.	.09 – .09¼	.09½ – .10
Tin oxide	lb.	..... –	.37 – .38
Zinc carbonate	lb.	.14 – .14½	.14¾ – .15½
Zinc chloride, gran.	lb.	.05½ – .06	.06¼ – .06¾
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08¼ – .08½
Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.16 — .16
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb.	.75 — .85
Benzoic acid, U.S.P.	lb.	.65 — .70
Benzoate of soda, U.S.P.	lb.	.55 — .57
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00½
Beta-naphthol, sublimed	lb.	.55 — .60
Beta-naphthol, tech	lb.	.26 — .28
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.53 — .55
Cresylic acid, 95-97%, dark, in drums	gal.	.48 — .50
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.70 — .75
Dimethylaniline	lb.	.38 — .40
Dinitrobenzene	lb.	.22 — .25
Dinitroclorbenzene	lb.	.22 — .24
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .65
H-acid	lb.	.85 — 1.00
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.14 — .15
Monoethylaniline	lb.	1.05 — 1.25
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.08 — .08½
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	2.50 — 2.60
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.70 — .75
Ortho-nitro-toluene	lb.	.12 — .15
Ortho-toluidine	lb.	.16 — .20
Para-amidophenol, base	lb.	1.25 — 1.30
Para-amidophenol, HCl	lb.	1.30 — 1.35
Para-dichlorbenzene	lb.	.14 — .16
Paranitroaniline	lb.	.75 — .77
Para-nitrotoluene	lb.	.60 — .70
Para-phenylenediamine	lb.	1.50 — 1.55
Para-toluidine	lb.	1.05 — 1.15
Phthalic anhydride	lb.	.36 — .38
Phenol, U. S. P., drums	lb.	.13 — .15
Pyridine	gal.	1.75 — 2.75
Resorcinol, technical	lb.	1.30 — 1.35
Resorcinol, pure	lb.	1.75 — 1.80
Salicylic acid, tech., in bbls.	lb.	.24 — .24½
Salicylic acid, U. S. P.	lb.	.25 — .26
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.25 — .28
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.10 — .12
Sulphanilic acid, crude	lb.	.24 — .26
Tolidine	lb.	1.20 — 1.30
Toluidine, mixed	lb.	.30 — .35
Toluene, in tank cars	gal.	.25 — .28
Toluene, in drums	gal.	.30 — .35
Xylidines, drums, 100 gal.	lb.	.40 — .45
Xylene, pure, in drums	gal.	.40 — .45
Xylene, pure, in tank cars	gal.	.45 — ....
Xylene, commercial, in drums, 100 gal.	gal.	.33 — .35
Xylene, commercial, in tank cars	gal.	.30 — ....

Waxes

Prices based on original packages in large quantities.

Bayberry Wax	lb.	$0.20 —	$0.21
Beeswax, refined, dark	lb.	.26 —	.28
Beeswax, refined,light	lb.	.30 —	.32
Beeswax, white pure	lb.	.35 —	.40
Candellila, wax	lb.	.25 —	.26
Carnauba, No. 1	lb.	.45 —	.46
Carnauba No. 2, North Country	lb.	.25 —	.25½
Carnauba, No. 3, North Country	lb.	.16 —	.16½
Japan	lb.	.17 —	.18
Montan, crude	lb.	.04 —	.04¼
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.04¼ —	.04½
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.02⅜ —	.....
Paraffine waxes, refined, 118-120 m.p.	lb.	.03 —	.03⅛
Paraffine waxes, refined, 125 m.p.	lb.	.03½ —	.03¾
Paraffine waxes, refined, 128-130 m.p.	lb.	.04 —	.04¼
Paraffine waxes, refined, 133-135 m.p.	lb.	.04¼ —	.04½
Paraffine waxes, refined, 135-137 m.p.	lb.	.05 —	.05¼
Stearic acid, single pressed	lb.	.09 —	.09¼
Stearic acid, double pressed	lb.	.09¼ —	.09¾
Stearic acid, triple pressed	lb.	.10¼ —	.11

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl.	280 lb.	$5.25 —	5.30
Rosin E-I	280 lb.	5.35 —	5.40
Rosin K-N	280 lb.	5.45 —	6.55
Rosin W. G.-W. W.	280 lb.	7.00 —	7.25
Wood rosin, bbl.	280 lb.	6.25 —	.....
Spirits of turpentine	gal.	.92 —	93½
Wood turpentine, steam dist.	gal.	.85 —	.....
Wood turpentine, dest. dist.	gal.	.70 —	.70
Pine tar pitch, bbl.	200 lb.	..... —	6.00
Tar, kiln burned, bbl. (500 lb.)	bbl.	..... —	10.00
Retort tar, bbl.	500 lb.	—	9.00
Rosin oil, first run	gal.	.37 —	.....
Rosin oil, second run	gal.	.39 —	.....
Rosin oil, third run	gal.	.46 —	.....
Pine oil, steam dist., sp.gr., 0.930-0.940	gal.		$1.90
Pine oil, pure, dest. dist.	gal.		1.50
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.		.46
Pine tar oil, crude, sp.gr.1.025-1.035 tank cars f.o b. Jacksonville, Fla.	gal.		.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.		.75
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.		.35
Turpentine, crude, sp. gr., 0.900-0.970	gal.		1.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.		.35
Pinewood creosote, ref.	gal.		.52

Fertilizers

Ammonium sulphate, f.a.s., N.Y.	100 lb.	3.75 —	.....
Blood, dried, f.o.b., N. Y.	unit	3.65 —	.....
Bone, 3 and 50, ground, raw	ton	27.00 —	28.00
Fish scrap, dom., dried, f.o.b. works	unit	3.10 —	3.20
Nitrate soda	100 lb.	2.90 —	3.00
Tankage, high grade, f.o.b. Chicago	unit	3.00 —	3.10
Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	5.50 —	7.00
Tennessee, 78-80%	ton	8.50 —	9.00
Potassium muriate, 80%	ton	33.50 —	35.00
Potassium sulphate	unit	1.00 —	.....

Crude Rubber

Para—Upriver fine	lb.	$0.18¾ —	.19
Upriver coarse	lb.	.13¼ —	.13½
Upriver caucho ball	lb.	.14 —	.14¼
Plantation—First latex crepe	lb.	.16¼ —	.16½
Ribbed smoked sheets	lb.	.16¼ —	....
Brown crepe, thin, clean	lb.	.14 —	....
Amber crepe No. 1	lb.	.16 —	....

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	$0.10 —	$0.10½
Castor oil, AA, in bbls.	lb.	.11½ —	.12
China wood oil, in bbls.	lb.	.13¼ —	.13½
Cocoanut oil, Ceylon grade, in bbls.	lb.	.08¾ —	.09
Coconut oil, Cochin grade, in bbls.	lb.	.09¼ —	.09½
Corn oil, crude, in bbls.	lb.	.11⅛ —	.11¼
Cottonseed oil, crude (f. o. b. mill)	lb.	.09¾ —	.10
Cottonseed oil, summer yellow	lb.	.12 —	.12¼
Cottonseed oil, winter yellow	lb.	.13¼ —	.13
Linseed oil, raw, car lots (domestic)	gal.	.86 —	.87
Linseed oil, raw, tank cars (domestic)	gal.	.82 —	.83
Linseed oil, in 5-bbl lots (domestic)	gal.	.89 —	.90

Olive oil, denatured	gal.	1.12 —	1.15½
Palm, Lagos	lb.	.07½ —	.07¾
Palm, Niger	lb.	.05¾ —	.06
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.09½ —	.10
Peanut oil, refined, in bbls	lb.	.12½ —	.13
Rapeseed oil, refined in bbls	gal.	.83 —	.84
Rapeseed oil, blown, in bbls	gal.	.86 —	.87
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.11¼ —	....
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.09⅛ —	....
FISH			
Light pressed menhaden	gal.	$0.54 —	....
Yellow bleached menhaden	gal.	.57 —	....
White bleached menhaden	gal.	.56 —	....
Blown menhaden	gal.	.61 —	....

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Asbestos, crude No. 1, f.o.b., Quebec, Canada	short ton	$900 00	$1,100.00
Asbestos, shingle stock, f.o.b., Quebec, Canada	short ton	70.00	—110 00
Asbestos, cement stock, f.o.b., Quebec, Canada	short ton	15.00	— 17.50
Barytes, ground, white, f.o.b. mills	net ton	17.00	— 23.00
Barytes, ground, off color f.o.b. mills	net ton	13.00	— 21.00
Barytes, floated, f.o.b. St. Louis	net ton	23.00	— 24 00
Barytes, crude f.o.b. mines	net ton	8.00	— 8.00
Casein	lb.	.10½	— .12
China clay (kaolin) crude, f.o.b. mines, Georgia	net ton	6.00	— 8.00
China clay (kaolin) washed, f.o.b. Georgia	net ton	8.00	— 9.00
China clay (kaolin) powdered, f.o.b. Georgia	net ton	12.00	— 20.00
China clay (kaolin) crude f.o.b. Virginia points	net ton	8.00	— 12.00
China clay (kaoli n)ground, f.o.b. Virginia points	net ton	13.00	— 20.00
China clay (kaolin), imported, lump	net ton	14.00	— 20.00
China clay (kaolin), imported, powdered	net ton	30.00	— 35.00
Feldspar, No. 1 pottery grade	long ton	6.50	— 6.75
Feldspar, No. 2 pottery grade	long ton	5.75	— 5.90
Feldspar, No. 1 soap grade	long ton	7.00	— 7.50
Feldspar, No. 1 Canadian, for mill	long ton	22.00	— 22.50
Graphite, Ceylon lump, first quality	lb.	.05	— .07
Graphite, Ceylon chip	lb.	.04	— .05½
Graphite, high grade amorphous crude	ton	18.00	— 45.00
Kieselguhr, f.o.b. mines, Cal	per ton	40.00	— ....
Kieselguhr, f.o.b. N. Y	per ton	55.00	— 60.00
Magnesite, calcined (crude)	per ton	12.00	— 15.00
Pumice stone, imported	lb.	.03	— .05
Pumice stone, domestic, lump	lb.	.05	— .05½
Pumice stone, domestic, ground	lb.	.06	— .07
Shellac, orange fine	lb.	.86	— .87
Shellac, orange superfine	lb.	.88	— .89
Shellac, A. C. garnet	lb.	.68	— .69
Shellac, T. N.	lb.	.83	— .84
Silica, glass sand, f.o.b. Indiana	per ton	1.25	— 1.50
Silica, sand blast material, f.o.b. Indiana	per ton	2.25	— 4 50
Silica, amorphous, 250 mesh, f.o.b. Illinois	per ton	16 00	— 16 00
Silica, building sand, f.o b. Pa	per ton	2.00	— 2.75
Soapstone	ton	12.00	— 15.00
Talc, 200 mesh, f.o.b. Vermont	ton	7.00	— 12.00
Talc, 200 mesh, f.o.b. Georgia	ton	7.50	— 12.00
Talc, 200 mesh, f.o.b. Los Angeles	ton	16.00	— 20.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh	per 1,000	$130.00
Carborundum refractory brick, 9-in	1,000	1100.00
Chrome brick, f.o.b. Eastern shipping points	net ton	41–44
Chrome cement, 40-50% Cr_2O_3	net ton	30–32
Chrome cement, 40-45% Cr_2O_3, sacks, in car lots, f.o.b. Eastern shipping points	net ton	30–32
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	32–37
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	27–30
Magnesite brick, 9-in. straight (f.o b. works)	net ton	55
Magnesite brick, 9-in. arches, wedges and keys	net ton	70

Plates, ¼ to 1 in. thick	2.48	2.38

*Add 15c per 100 lb. for trucking to Jersey City and 10c for delivery in New York and Brooklyn.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

GEIGER—The Sumter Farm & Stock Co. has preliminary plans under way for the establishment of a new mill for the manufacture of cottonseed oil specialties.

ANNISTON—The Farmers' Union Warehouse Co. is considering the erection of a new mill for cottonseed oil manufacture. Work will be commenced in the near future. G. W. Eichelberger is president.

California

OAKLAND—E. H. Hart, secretary of the Oakland Merchants' Exchange, is in negotiation with the La Blume Soap Co., Paris, France, for the erection of a local plant for the manufacture of high-grade soap products. A site is being selected. The project is estimated to cost about $1,000,000, including plant buildings and machinery.

PITTSBURGH—The King Mfg. Co. has completed the erection of a new local mill for the manufacture of plaster board specialties, and will commence production under an initial output of about 5,000 sq.ft. a day. This will be increased at a later date. R. W. King is president and general manager.

SAN FRANCISCO—The Magnolia Metal Co., Pacific Bldg., has awarded a contract to Frederick Moller, 180 Jessie St., for the erection of a new 1-story plant at Bryant and Sterling Sts., to cost about $15,000. Dodge A. Reidy, Pacific Bldg., is architect. Work will be commenced at once.

SAN FRANCISCO—The National Magnesite Products Corp., represented by Sterling Carr, 201 Sansome St., has acquired the property and equipment of the Sonoma Magnesite Co., in the Guerneville Section, Sonoma County, Cal., at public sale, for a consideration of about $175,000. The new owner plans for early operations at the plant and will make a number of improvements.

Florida

BAGDAD—The Bagdad Land & Lumber Co. has arranged for a bond issue of $1,200,000, a portion of the proceeds to be used in connection with the construction of its proposed new turpentine mill on a site recently acquired in Escambia County, Ala. W. B. Harbeson is president.

Illinois

HIGHLAND PARK—The North Shore Sanitary District, Lake Forest, Ill., has preliminary plans under way for the construction of a new purification plant on Gillette Ave., Highland Park, to cost about $125,000, including equipment. Alvord, Burdick & Howson, 8 Dearborn St., Chicago, are engineers.

Indiana

SEYMOUR—The Buhner Fertilizer Co. is considering tentative plans for the rebuilding of the portion of its plant, destroyed by fire, April 12, with loss estimated at about $50,000. Ferdinand Buhner heads the company.

Kentucky

ASHLAND—In addition to a number of improvements in its present plant, the Ashland Firebrick Co., Winchester Ave., will build a 1-story addition, 135 x 190 ft., to be equipped for general manufacture, to total about 50,000 firebrick and other refractory shapes per day. The building contract has been let. E. H. Gartrell is general manager.

LOUISVILLE—The Producers' Wood Preserving Co., an interest of the Ayer & Lord Tie Co., 80 East Jackson Blvd., Chicago, Ill., is completing plans and will soon commence the erection of its proposed new local creosoting plant, to cost about $200,000, including equipment. Oscar E. Bond, Marion E. Taylor Bldg., Louisville, is in charge.

Louisiana

MONROE—The Southwest Pulp & Paper Co. has acquired a tract of property in the vicinity of the Monroe-Columbia Highway, a few miles from the city, totaling about 18 acres of land, as a site for the erection of a new pulp and paper mill. Plans will be placed under way at an early date, and it is expected to begin construction later in the year. The plant is estimated to cost about $250,000, including equipment.

SHREWSBURY—Fire April 21 destroyed the local plant of the Armour Fertilizer Works, 209 West Jackson Blvd., Chicago, Ill., with loss estimated at about $250,000, including buildings, equipment and stock. It is said that the plant will be rebuilt.

CEDAR GROVE—The Louisiana Oil Refining Corp. has leased for an indefinite period the local refinery of the International Oil & Gas Corp., and will place the plant in operation at an early date for the refining of crude oil from the Bellevue field. A number of improvements will be made. The plant was shut down about a year ago, and has a rated capacity of 1,000 bbl. a day.

Maryland

EVERGREEN — The Loyola College Trustees, James A. S. McEneany, 700 North Calvert St., Baltimore, president, will soon take bids for the erection of a 2-story chemistry-biology building at the institution, estimated to cost about $200,000. Otto G. Simonson, Maryland Casualty Bldg., Baltimore, is architect.

SNOWHILL—The plant of the Snowhill Brick Co. has been leased by A. J. Laurenson and William F. Johnson, both of Norfolk, Va., who plan to place the works in operation at an early date. A number of improvements will be made.

BALTIMORE — The Oil Products Co. has leased the 3-story building at 302 North Holliday St. for a new local plant.

Massachusetts

EVERETT—A portion of the plant of the Beacon Oil Works, South Everett, including compressor building, was destroyed by fire April 14, with loss reported at $12,000.

Michigan

DETROIT—The Detroit Soda Products Co., 9077 West Jefferson St., is completing plans and will soon take bids for the erection of a 2-story addition to its plant, 60 x 80 ft. L. B. Alger is president.

Mississippi

JACKSON—The Hi-Power Mfg. Syndicate has leased a local building for the establishment of a plant for the manufacture of battery fluids and other chemical products. Operations will be commenced at an early date.

Missouri

KANSAS CITY—The American Foundry & Mfg. Co., Kansas City Life Bldg., will defer temporarily the erection of its proposed new 1-story foundry, 90 x 140 ft., at 18th and Manchester Aves., estimated to cost about $30,000. Plans have been drawn. H. H. Akers is general manager.

Montana

GREAT FALLS — The American Refining Co. is planning for the erection of an addition to its oil refinery, for general service operations and production.

New Jersey

WOODSTOWN—The South Jersey Farmers' Exchange is selecting a site for the erection of a new fertilizer-manufacturing plant, to replace its works destroyed several months ago with loss estimated at about $150,000. The new plant with equipment will cost close to a like amount.

HOBOKEN—The White Metal Mfg. Co., 1006 Clinton St., has commenced excavations for the erection of a 2-story addition to its plant on the Paterson Plank Road, North Bergen, to cost about $50,000. Leo Feinen, 3697 Boulevard, Jersey City, N. J., is architect.

WAYNE — Fire April 19 destroyed the Corning Mill at the local powder plant of E. I. du Pont de Nemours & Co., Wilmington, Del. It was caused by an explosion. The estimated loss has not been announced.

New York

LOCKPORT—The A. W. Jack Corp., North Transit Road, manufacturer of asbestos mill board and other asbestos specialties, is completing plans for the erection of the first unit of its proposed new plant, to be 1-story, 125 x 500 ft., and estimated to cost in excess of $300,000. George F. Hardy, 309 Broadway, New York, N. Y., engineer, will call for bids at an early date.

BUFFALO—The Webb Clean Sweep Co., manufacturer of floor-sweeping compounds and other chemical products, is planning for the erection of a new 1-story plant on Troupe St., near Westcott St. I. H. Webb heads the company.

ONEIDA—The Maxwell Steel Vault Co., 4 Warner St., has awarded a contract to Frazio & Millard, Oneida, for the erection of the first unit of its new plant, to be 1-story, 60 x 90 ft., and estimated to cost about $30,000, including equipment. Work will be commenced at once.

RENSSELAER—The Grasselli Chemical Co., 347 Madison Ave., New York, has plans under way for the erection of a 1-story building on local site.

Oklahoma

BARTLESVILLE—The Bartlesville Zinc Co. will make a number of improvements in its plant, including repairs to equipment. The works have been closed for the betterment program.

Pennsylvania

LOCK HAVEN—The Queens Run Refractories Co., is considering the erection of a new 1-story addition. Improvements will be made in the present plant. William Sleicher is president.

PHILADELPHIA—The United Gas Improvement Co., Broad and Arch Sts., has tentative plans under way for the construction of a new artificial gas plant, to cost in excess of $1,500,000. The exact location has not been announced.

PHILADELPHIA—The Shingle Leather Co., 315 Vine St., has completed plans for the erection of a new plant at Grays Ave. and 54th St. Work will be commenced at an early date.

ALLENTOWN — The plant of Robert A. Reichard, devoted to the manufacture of fertilizers, has been acquired at a public sale by Harry H. Shisler and associates for a consideration of $30,500. The plant represents an investment of $150,000. The new owners will organize a company and operate the works for the same line of manufacture as heretofore, including phosphates, etc. A number of improvements will be made.

Texas

ROBSTOWN—The Nueces County Water Improvement Commissioners, District No. 3, are planning for the installation of a new purification plant in connection with extensions and improvements in the local waterworks.

WEATHERFORD—The Weatherford Refining Co., operating a local oil refinery, has been reorganized. Plans are under way for the erection of an addition to the plant, with extensive improvements in the present refinery. New equipment will be installed. The company has increased its capitalization to $200,000.

MOUNT PLEASANT—The City Council will install a new filtration plant in connection with extensions in the local waterworks. H. S. Wilder is engineer.

BRECKENRIDGE—The Ebony Carbon Co. has made application to the State Railroad Commission for permission to build a local plant for the manufacture of hydro-gas carbon. The initial works will have a capacity of about 3,000 lb. of carbon black every 24 hours, consuming approximately 2,000,000 ft. of gas in this period.

Washington

CENTRALIA—The Vader Tile Co., organized to take over and operate the plant of the Standard Clay Co., has plans under way for the reconstruction of a large portion of the works, with enlargements in a number of departments. Additional equipment will be installed.

SEATTLE—The Pacific Oil Mills will soon commence the construction of an addition to the tankage department at its vegetable oil mills on East Marginal Way.

Canada

MONTREAL, QUE.—The Hochelaga Cement Co., Ltd., recently organized with a capital of $3,000,000, will operate a large local cement mill. The initial plant will have a capacity of about 2,000 bbl. a day, and this will be increased to 5,000 bbl. output at a later date.

New Companies

THE EASTERN CHEMICAL CO., Trenton, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are Harry and M. H. Bernstein, and Solomon R. Block, 137 East State St., Trenton.

THE MCMULLEN PETROLEUM & REFINING Co., 220 South State St., Chicago, Ill., has been incorporated with a capital of $75,000, to manufacture refined oil products. The incorporators are Frank R. Cain, Charles A. Snapp and Stillman T. Meservey.

THE PUGET SOUND REDUCTION CO., Buffalo, N. Y., has been incorporated with a capital of $150,000, to manufacture fertilizer products. The incorporators are E. Stengel, P. J. Ferkel and J. Gehm. The company is represented by Sullivan, Bagley & Wechter, Chamber of Commerce Bldg., Buffalo.

THE BARRON-NORCROSS SOAP CORP., Hamilton, Mass., has been incorporated with a capital of $10,000, to manufacture soaps and affiliated products. Harry Barron is president, and Austin L. Norcross, South Hamilton, Mass., treasurer.

THE WHEELING OXYGEN CO., Wheeling, W. Va., has been incorporated with a capital of $200,000, to manufacture commercial oxygen and kindred products. The incorporators are W. H. Frank, P. J. McGinley and James W. Ewing, all of Wheeling.

THE UNIFORM OIL CO., 1231 Calvert Bldg., Baltimore, Md., has been incorporated with a capital of $25,000 and 2,500 shares of stock, no par value, to manufacture oil products. The incorporators are W. Howard Hamilton, W. Woodward Cook and William S. Hammond.

THE SHEA CHEMICAL CO., 1107 White Bldg., Seattle, Wash., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are George A. Shea and F. W. Strang.

THE BERKSHIRE OIL CO., Pittsfield, Mass., has been incorporated with a capital of $25,000, to manufacture oil products. The incorporators are William S. and Irwin H. Farrar, and Adam D. Hall, all of Pittsfield.

THE COZZINS CHEMICAL CO., Madison, N. J., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are Fred A. Brown, William Scott and William J. Nicholson, all of Madison.

THE PITTSBURGH SLAG BRICK & TILE CO., Pittsburgh, Pa., has been incorporated under Delaware laws with capital of $100,000, to manufacture brick, tile and kindred products. The incorporators are Robert L. Taylor, William C. Taylor and C. Q. Markhart, all of Pittsburgh. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington, Del.

THE COLUMBIA ENAMEL CO., Albany, N. Y., has been incorporated with a capital of $50,000, to manufacture enamels and kindred products. The incorporators are J. J. Schulda, R. Phillips and A. P. Sponable. The company is represented by C. R. Watson, Albany.

THE FLO-TEX OIL CO., Tampa, Fla., has been incorporated with a capital of $150,000, to manufacture petroleum products. George M. Thompson is president; R. E. Moore, vice-president; and V. B. Thompson, secretary.

THE CASALE AMMONIA CO. OF AMERICA, INC., Jersey City, N. J., has been incorporated with a capital of 100 shares of stock, no par value, to manufacture ammonia and kindred products. The incorporators are George H. Russell, George J. Nutting and Samuel Drayton. The company is represented by the New Jersey Coroporation Agency, 243 Washington St., Jersey City.

THE ALCO CHEMICAL CORP., Brooklyn, N. Y., has been incorporated with a capital of $12,000, to manufacture chemicals and chemical byproducts. The incorporators are A. H. Green, H. M. Gordon and I. A. A. Blish. The company is represented by Samson Selig, 233 Broadway, New York.

THE DENMAN CORD TIRE CO., Edgemere, N. Y., has been incorporated with a capital of $100,000 under Delaware laws, to manufacture automobile tires and other rubber products. The incorporators are R. H. Johnson, Edgemere; A. H. Shapiro, New York; John A. Morris, Westchester, N. Y.; and Frank Fritts, South Beach, Conn. The company is represented by the Registrar & Transfer Co., 900 Market St., Wilmington, Del.

THE WOLVERINE OIL CORP., 711 West University Ave., Champaign, Ill., has been incorporated with a capital of $250,000, to manufacture oil products. The incorporators are Fred W. Green, Howard C. Lawrence and John W. Stipes.

THE WINEGAR PRODUCTS CO., Syracuse, N. Y., has been incorporated with a capital of $10,000, to manufacture boiler compounds and kindred specialties. The incorporators are C. E. Brown, J. S. Armstrong and R. S. Davis. The company is represented by R. T. Murray, attorney, Syracuse.

THE DIAMOND TWIN CORP., Hoboken, N. J., has been incorporated with a capital of $20,000, to manufacture chemicals and chemical byproducts. The incorporators are Ralph M. Ketcham, William A. Sands, Jr., and Edwin S. White, Clinton St., Hoboken.

THE VELVO-LITE PRODUCTS CO., 3826-28 Indiana Ave., Chicago, Ill., has been incorporated with a capital of $50,000, to manufacture paste specialties, etc. The incorporators are Harrington A. Talbot, J. W. Montgomery and T. L. Douglas.

THE JEWELL OIL CO. OF KENTUCKY, Lexington, Ky., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are John B. and M. H. W. Jewell, and Harry M. Rowe, all of Lexington.

THE WINCHESTER BRICK CO., Winchester, Mass., has been incorporated with a capital of $50,000, to manufacture brick, tile and other burned clay products. John K. Whiting, Longwood Ave., Brookline, Mass., is president and treasurer; Isaac S. Whiting, is vice-president.

THE INTERNATIONAL PRODUCING & REFINING CO., Wilmington, Del., has been incorporated with a capital of $500,000 under state laws, to manufacture refined petroleum products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE CONSTANT HEAT CORP., Albany, N. Y., has been incorporated with a capital of $200,000, to manufacture chemical heat packing, and other chemical products. The incorporators are O. L. and L. L. Perrault, and C. Z. Smith. The company is represented by E. A. Gifford, Albany.

TH ST. CLAIR SILICA CO., 744 North Third St., East St. Louis, Ill., has been incorporated with a capital of $30,000, to manufacture refined silica and silica products. The incorporators are W. D. Abraham, A. J. Kahle and William A. Luft.

THE SCUORZO CHEMICAL LABORATORIES CO., Newark, N. J., has filed notice of organization to manufacture chemicals and chemical byproducts. Ernest and Alfred A. Scuorzo, 235 Oliver St., Newark, head the company.

THE ES-TE OIL CO., Chicago, Ill., has been incorporated under Delaware laws with a capital of $2,000,000, to manufacture refined oil products. The incorporators are H. L. Casey, C. W. Smith and T. Goodrich, all of Chicago. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington, Del.

THE WELLSBURG PAPER CO., Wellsburg, W. Va., has been incorporated with a capital of $500,000, to manufacture pulp and paper products. The incorporators are George T. H. Hammond, Thomas George and Allen Burt, all of Wellsburg.

THE SOAP SALT CO., Tarentum, Pa., has been incorporated under Delaware laws with capital of $100,000, to manufacture washing compounds and kindred products. The incorporators are J. F. Henry, Tarentum; J. B. and L. H. Cowan, both of Brackenridge, Pa. The company is represented by the Capital Trust Co. of Delaware, Dover, Del.

THE HAT CITY FOUNDRY CO., Danbury, Conn., has been incorporated with a capital of $15,000, to manufacture iron, steel and other metal castings. The incorporators are F. A. Shepard, E. S. Roos and J. P. Fahy, all of Danbury.

POUCHER, TRABOLD & SIDNEY, INC., New York, N. Y., has been incorporated with a capital of $225,000, to manufacture leather products. The incorporators are R. I. Poucher, P. Sidney and F. W. Trabold. The company is represented by Churchill, Marlow & Hines, 63 Wall St., New York.

THE LEONARD CHEMICAL CO., 10 South La Salle St., Chicago, Ill., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are John A. Kelly, T. J. and A. M. Leonard.

THE CALVERT OIL CO., Fort Smith, Ark., has been incorporated with a capital of $25,000, to manufacture petroleum products. C. C. Calvert is president; C. A. Lick, vice-president; and W. E. Decker, secretary, all of Fort Smith.

THE BURTON HEIGHTS CO-OPERATIVE OIL CO., Wilmington, Del., has been incorporated under state laws with capital of $165,000, to manufacture oil products for motor and other service. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE MAWSON INK CO., Boston, Mass., has filed notice of organization to manufacture ink and kindred products. William F. Simpson, 334 Cambridge St., Allston, Mass., heads the company.

THE HART-PEDERSON GLASS CO., 3242 Carroll Ave., Chicago, Ill., has been incorporated with a capital of $10,000, to manufacture glass products. The incorporators are Walter V. Hart and Paul N. Pederson.

THE LIQUID SOAP CO., 128 North Wells St., Chicago, Ill., has been organized to manufacture soaps and other products. The company is headed by I. C. Brennan and T. Deutsch.

Capital Increases, Etc.

THE RUDOLPH PAPER CO., INC., 2740 Park Ave., New York, N. Y., has filed notice of increase in capital from $100,000 to $500,000.

THE Z. & M. INDEPENDENT OIL CO., Norwich, N. Y., has filed notice of increase in capital from $50,000 to $100,000.

THE SERVICE RUBBER CO., Chicago, Ill., manufacturer of rubber products, has filed notice of increase in capital from $500,000 to $1,000,000.

THE HOLSTON TILE CO., Rogersville, Tenn., has filed notice of increase in capital from $35,000 to $100,000.

THE CHEROKEE CHEMICAL CO., Gaffney, S. C., has filed notice of increase in capital from $50,000 to $200,000. George Riehl is secretary.

THE HERCULES WATERPROOF CEMENT CO., Mutual Life Bldg., Buffalo, N. Y., has arranged for reduction in capital from $150,000 to $50,000.

THE AMERICAN VULCANIZED FIBRE CO., Wilmington, Del., has filed notice of change of name to the Fibre Securities Co.

THE BRIDGEPORT BRASS FOUNDRY, INC., Bridgeport, Conn., has filed notice of dissolution under state laws.

THE MANATI SUGAR CO., 112 Wall St., New York, N. Y., has disposed of a bond issue of $8,000,000, the proceeds to be used for general operations, financing, etc.

THE NEW ENGLAND OIL REFINING CO., 19 Milk St., Boston, Mass., has arranged for the sale of bonds for $1,000,000, to be used for general operations.

Industrial Notes

KURT MUNZINGER of Buffalo, N. Y., sailed recently from New York for Havre, France. From Havre Mr. Munzinger will go to Barcelona, Spain, to open a foreign office for Pratt & Lambert, Inc., Buffalo, manufacturer of varnish. He will also care for the company's interests in Spain, Holland, Denmark, Sweden, Norway and Finland.

THE PFAUDLER CO. has moved its New York office from 110 West 40th St. to 8 West 40th St.

THE COMBUSTION ENGINEERING CORP., New York, announces that it has recently completed arrangements with the Power Plant Equipment Co. of Kansas City, Mo., to represent it in that territory.

THE SOUTHWESTERN ENGINEERING CO., Los Angeles, Cal., has recently appointed D. W. Salsbury Eastern manager, with offices at 200 Broadway, New York City. Mr. Salsbury will act as Eastern manager for the Southwestern Condenser Co. and will have charge of all Eastern sales for the MacCamy condenser and intercooler.

THE DRIVER-HARRIS CO., Harrison, N. J., announces that on May 1 its Chicago branch moved to larger quarters at 562-574 West Randolph St.

THE IRON PRODUCTS CORP., the Central Foundry Co., the Central Iron and Coal Co., the Chattanooga Iron and Coal Corp., the Molby Boiler Co. and the Central Radiator Co., have moved their New York offices to 41 East 42nd St.

W. H. CAMPBELL, for the past 2 years general sales manager of the Charleston Industrial Corp. at Nitro, W. Va., announces the opening of offices as W. H. Campbell, Inc., at 30 Church St., New York City. This business has been incorporated for the sale of new and carefully inspected used chemical, refrigeration and power apparatus. While with the Charleston Industrial Corp. Mr. Campbell devoted his time to the sale of equipment for the former government munitions plant at Nitro, purchased by the company.

New Publications

INDUSTRIAL STABILITY is the title of a book, Vol. V, No. 1, dated January, 1922, published by the Society of Industrial Engineers, which is a complete report of the proceedings of the seventh national convention held under the auspices of the Society of Industrial Engineers at Springfield, Mass., Oct. 5, 6 and 7, 1921.

THE DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH (London) has published Special Report No. 1, by the Fuel Research Board, on "Pulverized Coal Systems in America," by Leonard C. Harvey.

THE IMPERIAL INSTITUTE (London) has published a new edition, revised and enlarged, on "Potash," by Sydney J. Johnstone, which has been prepared under the direction of the Mineral Resources Committee of the Imperial Institute with the assistance of the scientific and technical staff. Copies can be obtained from John Murray, Albemarle Street, W., London, at 6s. net.

THE IMPERIAL MINERAL RESOURCES BUREAU has published "Laws and Regulations Relating to Lead Poisoning," being an analysis with texts of the laws and regulations made in the chief industrial countries to prevent Plumbism, by Gilbert Stone. Copies can be obtained from H. M. Stationery Office, London, England, at 5s. net.

Manufacturers' Catalogs

WILSON-MAEULEN CO., New York, has issued its fourteenth Pyrometer Catalog. It illustrates and describes the Tapalog, both single- and multi-record pyrometer recorders, high-resistance Monopivot indicator, Monopivot pyrometers, pyods and accessories.

THE SOUTHWESTERN CONDENSER CO., 1223 Hollinsworth Bldg., Los Angeles, Cal., has issued Bull. A-5, on "Intercoolers and Aftercoolers for Compressors."

THE ELECTRO METALLURGICAL SALES CORP., New York, has just received from the press its new catalog entitled "Electromet Brand Ferro-Alloys and Metals." This attractive 26-page booklet gives a brief description of the most important Electromet brand products and their uses in the fields of ferrous and non-ferrous metallurgy, together with some historical statements.

W. S. ROCKWELL CO., New York, in Bull. 241, on "Forging and Heating Furnaces," has prepared a booklet on the need for better heating in forging and forming practice. It indicates some fundamental principles affecting the quality and cost of forgings and other formed parts that are generally overlooked in practice. It is claimed that proper application of the ideas outlined should lead to better and cheaper products, irrespective of the form of furnace or fuel employed. Illustrations of typical equipment are shown, with descriptions of the heating and handling methods employed to meet a wide variety of plant and manufacturing conditions, form and cost of available fuels.

STRUTHERS-WELLS CO., Warren, Pa., manufacturer of steel plate equipment for the chemical, petroleum refining, iron and steel, creosoting, paper, soap, alcohol and related industries, has published a new and well-illustrated catalog. Descriptions of plate shop, engineering department, welding shop, foundry, machine shop are complete and well illustrated. Among the products are tanks, kettles, coolers, agitators, stills, flues, boilers, etc.

Industrial Developments

CERAMIC—The Blackwell Brick Mfg. Co., Blackwell, Okla., has resumed operations on a capacity basis, following a shut-down for some time past. More than 60 men will be employed, with output totaling 40,000 bricks a day.

All brick-manufacturing plants in the Birmingham, Ala., district are operating on a full-time, full-capacity basis.

Potteries at East Liverpool, O., and vicinity have increased capacities to 90 and 95 per cent of normal. A number of chinaware plants are operating under full production. During March a total of 13,000 packages of chinaware was shipped from the Sebring, O., territory, establishing a new high record.

RUBBER—The Vulcanized Rubber Co., Morrisville, Pa., manufacturer of hard rubber products, has increased operations to a capacity basis. Orders on hand insure this basis of output for more than 12 months to come in a number of departments. Employment is being given to 400 persons.

The Lehigh Tire & Rubber Co., New Castle, Pa., is increasing production and adding to its working force. Close to normal operations are being maintained.

The Firestone Tire & Rubber Co., Akron, O., has advanced production to a basis of 22,000 tires a day, as against 20,000 tires during the early weeks of April.

The Goodyear Tire & Rubber Co., Akron, O., has increased manufacture from 22,000 to 24,000 tires a day. About 1,000 additional employees have been added to the working force during April.

GLASS—The Sneath Glass Co., Hartford City, Ind., has resumed operations in its blowing department, following a curtailment for a number of weeks. Improvements have been made for increased production.

The majority of the large glass bottle-manufacturing plants at Millville, N. J., have adopted a full time operating schedule. Tube workers in this section have accepted a wage reduction of 15 per cent.

LEATHER—The B. D. Eisendrath Tanning Co., Racine, Wis., is increasing production in its calf leather department, and is arranging for further enlargement at an early date.

The American Hide & Leather Co. is increasing production at its tanneries in the Chicago, Ill., district for calf and grain material. The upper leather plants of the company in different parts of the country are running at 50 to 100 per cent capacity, with present average in excess of 75 per cent.

The Continental Leather Co., Philadelphia, Pa., is advancing the production schedule in the hide departments at its two tanneries in Virginia. Plans are under way for the establishment of a new leather plant in the vicinity of Elkton, Va.

IRON AND STEEL—The Republic Iron & Steel Co., Youngstown, O., has resumed operations at its bessemer plant, idle for more than a year past. The company now has thirteen sheet mills in service in this district, and has also resumed at its plate mill.

The Crucible Steel Co., Pittsburgh, Pa., has blown in another blast furnace at its mills.

The McKinney Steel Co., Cleveland, O., is arranging for the immediate resumption of operations at its open-hearth plant. Four furnaces will be lighted.

The Bethlehem Steel Co. is increasing production at its Steelton, Pa., works. Blast furnace "B" at this plant, which has been out of commission for about a year past, will be blown in within the next fortnight, for pig-iron production. Operations are being advanced in the coke-oven department, and men added to the working force.

The Woodward Iron Co., Birmingham, Ala., has made its No. 2 Vanderbilt furnace ready for operation, and the unit will be blown in at once.

The Tennessee Coal, Iron & Railroad Co. is making ready to place another bessemer furnace in operation at its Ensley, Ala., works.

The LeMoyne Steel Co. has resumed operations at its plant at New Eagle, near Washington, Pa., following a shut-down for several months.

The Eastern Rolling Mill Co., Baltimore, Md., manufacturer of steel sheets, is arranging for an immediate advance in production from 90 to 100 per cent capacity, the first that the mill has been on this basis for some time past. Additions are being made to the working force.

The Newport Rolling Mill Co., Newport, Ky., will place additional sheet and tin mills in service during the next fortnight. A total of eleven mills are now in operation at the works. The working force is being increased.

MISCELLANEOUS—The Atlas Powder Co. has resumed production on a full-time basis at its plant at Tamaqua, Pa.

The Vulcanite Cement Co., Vulcanite, N. J., is maintaining full operations at its local plant, and has advanced the wages of employees 6 cents an hour. The Edison Portland Cement Co., New Village, N. J., in this same district, is running full, and has announced a wage increase for operatives of 5 cents an hour.

The American Trona Corp. has reopened its potash plant at Searles Lake, Cal., following a shut-down for nearly a year past.

The Atlas Mineral Products Co., Mertztown, Pa., has resumed operations at its plant, following a suspension of operations for some time past.

Coming Meetings and Events

ASSOCIATION OF CHEMICAL PLANT EQUIPMENT MANUFACTURERS will meet at the Chemists' Club, 52 East 41st St., New York, on May 10, to complete organization, elect officers and oppoint committees.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold a joint meeting with the Pacific Division of the association, on the occasion of the annual meeting of the latter, in Salt Lake City June 22 to 24.

AMERICAN ASSOCIATION OF ENGINEERS will hold its eighth annual convention at Salt Lake City, Utah, June 4-6.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, Canada June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its nineteenth annual meeting at Bigwin Inn, Bigwin Island, in the Lake of Bays district, Ontario, Canada, on June 21, 22 and 23.

AMERICAN OIL CHEMISTS' SOCIETY will hold its annual meeting at the Grunewald Hotel, New Orleans, La., May 8 and 9.

AMERICAN PULP AND PAPER MILL SUPERINTENDENTS ASSOCIATION will meet in Kalamazoo, Mich., June 1, 2 and 3.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at Atlanta, Ga., May 8-11.

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting at the Bureau of Mines auditorium, Pittsburgh, Pa., on May 25 and 26. The International Steel Exposition and Convention of the society will be held in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

ANNUAL SAFETY CONGRESS of the NATIONAL SAFETY COUNCIL will be held in Detroit, Mich., Aug. 28-Sept. 2.

CANADIAN INSTITUTE OF CHEMISTRY and the SOCIETY OF CHEMICAL INDUSTRY will hold their annual meetings in Ottawa May 15-17.

CERAMIC SOCIETY (London) is to have a foreign trip to Sweden and Denmark from May 27 to June 10.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

IRON AND STEEL INSTITUTE (British) will hold its annual meeting on May 4 and 5 at the House of the Institution of Civil Engineers, Great George St., S. W., 1, London.

NATIONAL ASSOCIATION OF PURCHASING AGENTS EXPOSITION (the "Informashow") will be held in connection with the seventh annual convention of the association at Exposition Park, Rochester, N. Y., May 15-22.

NATIONAL COAL ASSOCIATION will hold its annual meeting at Congress Hall, Chicago, May 24-25.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NATIONAL FERTILIZER ASSOCIATION will hold its twenty-ninth annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 12.

NEW JERSEY CHEMICAL SOCIETY will meet at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

TANNERS' COUNCIL will meet at the Copley-Plaza Hotel, Boston, May 4 and 5.

The following meetings are scheduled to be held in Rumford Hall, the Chemists Club, New York: May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting: June 9—American Chemical Society, regular meeting.

Chemists' Club Employment Bureau

FOR many years the Chemists' Club of New York has maintained an employment bureau for the benefit of chemists. The small service fee charged has made it possible for the bureau to show a profit in good times, but in bad times, when it really can be of the greatest benefit, it becomes a liability. At the last meeting of the American Chemical Society it was proposed to turn the bureau over to it, but the Council rejected the proposal. In our judgment this was a mistake, because the large membership of the Society would give greater scope to the work of the bureau. Further, this business of fitting men to the places where they belong is a function that the Society might well assume in the interest of stabilizing chemical employment. Its fears that the Society might become involved in responsibility for recommendations are quite groundless, and other objections were without much force. Nevertheless the Society rejected the offer, and the bureau is to remain with the Chemists' Club. It will continue under the direction of Dr. MOODY, who has succeeded the late Prof. BASKERVILLE as director of the department of chemistry of the College of the City of New York. Under his past direction the bureau has rendered splendid service for a number of years, and we commend it to our readers.

The Beginnings Of Science

UNFORTUNATELY to many students who are at once intelligent and diligent the beginnings of both chemistry and physics are difficult and dull. Many who have "had" or "done" these studies remember them as so many hours of misery which are recalled with no enlightenment whatever. They studied to pass examinations and then the subjects were dismissed.

How then are we to get the scientific vision spread abroad among the intelligent part of the community? What seems needed rather than so many hours of chemistry or physics or biology as "a science" which leads to the passing requirement at school or college is a more general and correlated course in science as a whole. Dr. OTIS W. CALDWELL, director of the Lincoln School of Teachers College, Columbia University, with Prof. W. L. EIKENBERRY of the University of Kansas, wrote a textbook several years ago on the subject that points out the road. The sciences are called on for explanation indiscriminately as needed under the project method of teaching. Various efforts by other authors along similar lines have appeared since then. There is now in process of publication by Putnam's a beautiful exposition in four volumes called "The Outline of Science" by Prof. J. ARTHUR THOMSON of Aberdeen. Later and cheaper editions may bring it also into schools. It begins with the most engaging introduction to astronomy we have ever read and then proceeds along lines of biology, geology and physical chemistry in the first and only volume so far published.

Of course, in secondary schools we have the difficulty of preparing for college entrance examinations, but these difficulties are bound to be solved some day. Our contention is that the better way to begin science is as one great co-ordinated empire of knowledge. We have specialized too much at the beginning, and this does not lead to wisdom or even to scholarship. Everyone needs this larger vision to illuminate life. We men of science need it so that we may sense co-ordination and perceive the truth. Let's teach the high lights of nature to all, and then those who specialize in their work will be more enlightened than we of this generation.

Chemistry as the Foundation for Medicine

IT WAS along in about 1896, in conversation with the late Dean HENRY BOWDITCH of the Harvard Medical School, that we inquired where his best students came from. "Harvard College, perhaps?" we asked, as though, in such a Brahmin atmosphere as Bowditch Hill in Jamaica Plain, no other thought was possible. "Not at all," replied the old master of physiology. "Harvard is like any other college; some students are well prepared, and some are not. There is one place and one only in the United States from which they come inspired by a great teacher, and that is the Sheffield Scientific School of Yale. Their contact with Professor CHITTENDEN there is wholly unique. He gives them a remarkable course in physiological chemistry and he makes them understand. It is a great pity that there are not more like him. His students get the scientific attitude of mind. They come here with the chemical curiosity; with the will to search where the treasure is hid. Indeed, I may say we have as students graduates from the Sheffield Scientific School who have studied with CHITTENDEN, and then we have others. It is hard to make a comparison between them." That was about 1896. By 1898 the Corporation of Yale, having had difficulty in finding a good director for Sheff, took Dr. CHITTENDEN from his illuminating work as professor, promoted him out of the sphere of it and into the adjudication of such serious problems as what to do with a student who is laggard in his attendance at chapel, or the settling of quarrels between two boys, or determining whether X, who is deficient in English, may or may not play on the football team.

To be dean of a college is an honorable calling. So it is to be president of a bank or agent for HENRY FORD'S automobiles. But these things do not compare with teaching, real teaching, which is the greatest of all

the arts. Here was the one place in America where students of medicine were getting the start they needed, and it was put out of commission, so far as they were concerned, by the "promotion" of a professor.

Dr. BAILLY of Texas says we have far too many students of chemistry at this time. Not too many for the general good, but too many to find good places. So he suggests that they be inducted into organic research, and that with this and with biological chemistry as working capital to help them to establish themselves in the study of medicine we may look for a new generation of physicians. We all know the difference between the few physicians who have chemical understanding as diagnosticians and as physicians who know what to do, and the many who have only that smattering of chemistry which is the usual equipment of the practitioner.

Had it not been for the unfortunate, short-sighted—indeed almost blind—decision of the authorities of the Yale Corporation back in 1898 when they took Dr. CHITTENDEN from his chair of physiological chemistry and put him at the desk of the dean, we should have had more of those superpractitioners of medicine today who have "the will to search where the treasure is hid."

At the regular meeting of the Corporation on March 11, very complimentary resolutions were adopted over Dr. CHITTENDEN'S successful leadership of the Sheffield Scientific School for nearly a quarter of a century. And well they might resolve to this effect, for Dr. CHITTENDEN is a man of rare ability, and whatever he does he does well. But we think the Corporation should also have passed a vote of censure upon itself for its act in 1898 when, for its own convenience, it robbed the profession of medicine of so important a source of inspiration. It was an act that without doubt condemned a large number of persons to untimely death.

Nickel in Steel vs. Brains in Heat-Treatment

SOME incredulous questioning was leveled at Dr. RICHARD MOLDENKE at the recent meeting of the American Electrochemical Society when he stated that a leading German steel foundry was now able to produce plain carbon steel castings the equivalent of 4 per cent nickel steel castings made before the war. The details were not forthcoming. Apparently they were in line with the steps which German metallurgical industry had been forced to take by reason of war shortages of alloys, deoxidizers and high-quality ores. Captured ordnance was often full of metal of most suspicious chemical analysis, yet apparently good enough for the stresses it had to bear. The speaker inferred that such things were possible only by minute attention to correct metallurgical practice at every stage; ordinarily correct chemical composition is an indication that such painstaking care had been taken. Yet it is the care which is essential; given that, the composition may be what it may.

To a certain degree that is true, but if the practice is right the chemical analysis will usually come out right at the same time. For instance, a steel or iron which has been desulphurized must first have been deoxidized, and the quality in the product may actually be caused by freedom from gas rather than freedom from sulphur. But nickel is supposed to give certain peculiar and unique qualities to metal which ought therefore to be lacking when nickel is absent. One might cite the toughness and resistance to cracking which a nickel-steel armor plate exhibits when hit by a high-velocity shell if he were sure that this toughness were not due to a laminated structure caused in turn by non-metallic inclusions (dirt) rather than nickel!

Is not the wonderful German metallurgy which produced carbon steels the equivalent of nickel steel only an indication of what is going on elsewhere among up-to-date metallurgists? Perhaps they have known for some time that good nickel steel is not the easiest thing in the world to make, and have also discovered that sound, clean, simple steels can be wonderfully improved by correct heat-treatment. In other words, were they not making a mediocre nickel steel 10 years ago, while today they are making an excellent heat-treated carbon steel?

That this is at least a reasonable assumption may be inferred from the following: Hütte (1915), the reliable German engineering handbook, quotes the following physical properties for annealed 4 per cent nickel steel castings for machine parts: ultimate strength, 78,000 lb. per sq.in.; elastic limit, 50,000 lb. per sq.in.; elongation, 25 per cent; reduction in area, 55 per cent. This would probably be acceptable to them, but is far from being as good as can be obtained. Quoting from tests taken from mill production, HALL, NISSEN and TAYLOR (1919) quote many double-treated 0.26 carbon steel castings made in America which average ultimate strength 83,000 lb. per sq.in., elastic limit 51,000 lb. per sq.in., elongation 30 per cent, reduction in area 58 per cent, Fremont impact number 28, cold bend about 1 in., 180 deg.

Would you insist on nickel in the steel or brains in the heat-treatment?

Learning How to Think

IN THEORY we are always ready to admit that as a race we are going to make progress along new lines in future, but in practice we rather stick to the line of developing and expanding old ideas. We are disposed to extrapolate rather than seek to strike off at a tangent.

Just lately there is rather a new idea going the rounds, that while in the last hundred years development has been along the line of subjugating material forces, the next hundred years is going to see great development in subjugating the human brain—in other words, in learning how to think.

There are those to whom this prediction will not appeal. They are jealous of our ability, or supposed ability, to think, and at once suspect that the proponents of this new notion are actuated by a belief that most of the subjugation of materials and physical forces has been accomplished. Perish the thought, they are likely to explain, that we are any more than on the threshold, that we have done more than gather up a few grains of sand on the ocean's shore!

We may perhaps get some distance toward a fair viewpoint by comparison and analogy. We can observe in some cases what men's aspirations and expectations used to be, and note whether they have been fulfilled. A convenient case is found in railroading. The history of steam railroading in the United States covers less than a century. Go back half way, and we find certain train speeds achieved, with expectation that speeds would increase almost indefinitely, but the in-

crease has not occurred. Twenty years ago an 18-hour train between New York and Chicago was established, but this was achieved by the train keeping at it rather than by its going faster than trains had gone many years earlier. The speed of the fastest trains has increased but little in the second half of railroad history to date.

It is no dreadful thing to admit that along certain lines we have succeeded, have got along far enough, and can afford to go in for wholly new things. It is only about 20 years since we began developing physical efficiency in performing manual operations, and there are not a few now who believe we have gone too far, that we have been trying to produce what really involves a greater drudgery in work. The ergograph helps to tell us when and how long the rest periods for the muscles should be, but it is certain we are not living our lives rightly if we mold them from cradle to grave with ergograph records as the sole rule of faith and practice.

Now, as a matter of plain fact, probably everyone who really thinks knows that he does not know how to think. He has very likely had moments of inspiration that have been depressing rather than elevating, through showing what a waste of time the rest of life has been without similar quick and successful thinking. Here again there will be those who will object, holding that this is merely some fresh press-agent stuff for that fool psychology. Even though most people will admit that "psychology" as it has been taught has been rather dry, here is another point at which we can use analogy and comparison. There was "political economy," invented a long while ago and justifiably dubbed "the dismal science." Lately it has developed into something interesting and very useful, sometimes called "quantitative economics," not because it has made basic discoveries or formulated new theories, but because facts have accumulated, statistical and otherwise. Psychology is in line for a similar development. It is getting away from the question of whether or how an amœba thinks, and in the next few decades it may tell us, not how we think when we think the wrong way, but how we ought to think so that instead of there being an occasional flash of genius in a brain here and there we shall all be geniuses all the time. Then we can take things easy.

Lowering Costs Through Material Handling

IT HAS long been a recognized fact and accepted as common practice that bulky raw materials could be handled by mechanical equipment in a more economical and expeditious manner than by manual labor. We are so used to seeing coal, stone, sand, gravel, ore, sugar cane, pulpwood and similar material handled in this way that the fact has ceased to arouse much interest. We see the raw materials unloaded and stored, and pass on without thought as to how these are handled beyond the first storage point.

But what happens to them is really of great importance. Suppose we ask how many times each pound of raw material must be moved before the finished product is obtained and how much this movement costs. An illuminating example comes to mind. A plant manufacturing refractory brick had the raw materials delivered by rail from a trestle directly into bins. From that point—through every process, grinding, mixing, molding, drying, burning, storing and shipping—the material was entirely transported by hand in wheelbarrows. One movement consisted in transporting the brick from the drying shed to the kilns. It required eight barrowmen two days to wheel sufficient brick for one charge. At a rate of $4.50 each per ten-hour day this brought the cost of transporting the brick for a single kiln charge up to $72, or about $3.50 per ton.

The cost of discharging the kiln to storage was almost as great. There were five other wheelbarrow handlings for each brick besides the two mentioned above. In addition there were numerous intradepartment handlings, some of which possibly could not be eliminated; and which brought the total handling up to 28 pounds of material for each pound of product. As a result, handling operations occupied almost two-thirds of the labor of the plant and accounted for approximately one-half of the cost of the finished brick.

This, perhaps, is a particularly bad case; but many others exist which are almost as startling. Anywhere from one-third to nine-tenths of the cost of manual handling can be saved by the application of machine equipment in a plant where it is at all possible to install it; and this means with the interest charges on the investment and the depreciation charges directly charged to the handling costs. It is of course necessary to make an analysis of a plant before any handling equipment is installed, as it is a matter for careful study and skilled judgment as to just what equipment will best serve any special case. Most of the failures of material-handling installations have been due to the fact that the equipment used has not been proper for the plant where installed. The number of industries, however, in which some improvement cannot be made through the use of the proper equipment is few indeed.

There are additional benefits derived from the correct application of handling equipment, all of which have either a direct or an indirect effect in lowering costs. In many plants where the actual manual handling is less than in the example cited above, or where the process of manufacture is more complicated and more difficult to control, the enhanced efficiency following the installation of handling equipment eases the task of management and greatly lowers the incidental costs. This may be due to less space requirement for the same production, more rapid movement of goods in process, less quantity of goods in process inventory, a more easily determined and steadier output contributing to more efficient work in sales and purchasing, and the speeding up of labor in an unconscious effort to keep the pace of the machines.

The objection is often raised that handling equipment adds complication to the plant, requires an increased force of mechanics to care for it, and tends to hold up production through breakdowns. The first and second of these objections have proved in practice to be negligible, while the third, at one time true, no longer is important, as the handling equipment available is at least as reliable as the other equipment in use in most plants.

It seems that only ignorance of the actual accomplishments of handling equipment and inertia toward the acceptance of new methods have prevented a much greater application of mechanical handling. We believe that the increased production efficiency and lowered cost of production to be obtained through this equipment make it vitally important for all who manage or operate industries to study their plants with a view to obtaining to the full the advantages which may follow their use of such equipment.

Ghosts and Undeveloped Senses

To the Editor of Chemical & Metallurgical Engineering

SIR:—Here's Sir Arthur Conan Doyle on a lecture tour talking about ghosts, and whenever they talk about ghosts we poor chemists are bombarded with questions. But as soon as we undertake to present the requirements for sensory phenomena, we are likely to be informed that we don't know anything about the whole subject (which is correct, so far as most of us can understand), on the ground that these spirits and the stuff they are made of are immaterial—and that worries us again, because we want to know how they can be seen and felt and heard, if they are immaterial.

Sir Oliver Lodge and Sir Arthur Conan Doyle insist on the postulate of ether for their familiar manifestations; but to most of us ether is needed only for the wave theory of light, and in current thought this postulate is less firmly insisted upon than it was 10 years ago. If we postulate ether at all, we must postulate it as so dense that matter is, in effect, holes in the ether rather than particles of any sort.

In the Orient, spirits are not such ghosts as we discuss and fear if we think we see them. In Japan, for instance, in Buddhist temples after the proper offerings have been made and the requisite prayers said, it is held that the spirit of one departed comes sailing through the air like an infinitely minute spark which penetrates any wall, and is too small to be seen or felt. We, on the other hand, want them life-size, but shadowy enough to convince us that they are really ghosts, and not solid persons.

A big, fifteen-dollar book by Baron Albert von Schrenck-Notzing, M.D., of Munich, was published in Germany in 1913, and the English translation appeared in 1920 under the title "Phenomena of Materialism" (Duttons). This brought out a tissue-like manifestation emanating from a medium known as Eva C., a French girl, which Dr. Schrenck called "teleplasm." It was a moist, film-like substance that usually, but not always, came from her mouth, and occasionally took rather vague shapes—and then seemed to go back again. It was cool and moist to the touch. Sir Arthur refers to some such ghost-stuff which he calls "ectoplasm," which is probably the same sort of emanation. It seems more like some kind of a ruminant emanation than an honest-to-goodness ghost to one who is not gifted with the faculty of ready belief.

What the spiritualists seem to have missed by clinging fast to the ether theory is what may happen without it. We cultivate but two of our four major senses: sight and hearing. Smell we neglect utterly, and touch we know nothing about. Our eyes perceive light waves from $\frac{1}{60{,}000}$ to $\frac{1}{37{,}000}$ of an inch in length. Longer or shorter we do not see. Our ears hear atmospheric waves from one inch to a hundred feet in length, and we have no organs of apprehension beyond these limits. Therefore the most amazing and exciting phenomena may take place within a room, may frighten insects, but leave no impression on us the while we think everything is at once quiet and dark. Now since we know nothing of touch and pay scarcely any attention to it so long as we can see, we have in this sense a vast field of the unknown, which is exactly the place for ghosts. For the very reason that we know so little, nobody can deny that a person who is supersensitive to touch may become cognizant of all sorts of shapes and sounds and goings on to which the rest of us are blind and deaf and numb. Why insist that we can see that which is not matter when all these goings on are possible? It is a splendid chance, and we are amazed that the mediums have not adopted it. MARTIN SEYT.

Hardness of Solid Solutions

To the Editor of Chemical & Metallurgical Engineering

SIR:—It occurred to me, after hearing Dr. Jeffries' able presentation of "The Slip Interference Theory of the Hardening of Metals" before the February meeting of the Mining Engineers, following his very important paper published in your journal for June 15, 1921, that there is one point which needs to be emphasized in connection with the hardness of solid solution alloys. Suppose we take pure nickel and mix a little iron with it. Nickel happens to crystallize in the face-centered cubic structure. In going into solution, an atom of iron replaces an atom of nickel, but it does so at the expense of a certain amount of distortion in the position of the surrounding nickel atoms, and the extent to which that distortion of position may penetrate into the surrounding nickel is something concerning which we know nothing at present. Ordinarily, the same conditions of force exist throughout the entire crystal of pure nickel. If an iron atom be introduced at any one point, either that iron atom attracts the nickel atoms with a little bit more force than nickel atoms attract each other, or it attracts them with a little bit less force; or, in the extremely rare case (I scarcely can conceive of it as actually occurring), it exerts identically the same force. That last alternative may be put out of mind. In the other cases, the field of influence, the knot, the key, or whatever it may be called, that corresponds to the iron atom is a good deal larger in extent than the diameter of the atom itself. It conceivably might extend for four, five, six, ten or more atom diameters before displacement of the nickel atoms from their normal position would be so slight as to be entirely negligible. ANCEL ST. JOHN.

Non-Flammable Mixtures of Solvents

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your March 29 issue there appeared an article by Sievers and McIntyre entitled "Non-Flammable Mixtures of Organic Solvents for Vegetable Oil Extraction," which seems to me to call for some comment. The authors first proceed to discuss the determination of the limiting amount of the vapors of flammable solvents such as benzene, gasoline, etc., which can be mixed with vapors of a non-flammable solvent

such as carbon tetrachloride before a flammable mixture results. Now it is obvious that none of the so-called flammable vapors are really flammable by themselves, but only when mixed with oxygen. Furthermore, it is a theoretical as well as an experimental fact that all such vapors when mixed with air are flammable only within quite narrow limits of concentration. For instance, at ordinary temperatures and pressures, the limits for benzene vapor are about 1.5 per cent and 6 per cent by volume.

The method of testing for flammability outlined in the article referred to was very indefinite, no mention being made of the amount of air admixed with the vapors. In fact, one is led to infer that the mixture through which a spark was sent consisted purely of the vapors in question. If this is so, the fact that ignition was obtained in some cases would certainly contradict all the previous theoretical and experimental evidence. If, on the other hand, the vapors were mixed with air during the test, it is apparent, from the nature of the test as outlined, that the concentration of the solvent vapors must have been indefinite and consequently the possibility of an ignition is determined not only by the relative amounts of, say, benzene and carbon tetrachloride, but also by the concentration of oxygen. In view of these facts, it does not seem that one is justified in drawing any conclusions from the tests as to the effect of non-flammable liquids on the flammability of benzene and gasoline.

Newtonville, Mass. BARNETT F. DODGE.

Notes on the Manufacture of High-Speed and Tungsten Steels

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with great interest J. W. Weitzenkorn's notes in your issue of March 15, 1922, which are a remarkable confirmation of the theory that carbides in high-speed steels are not made soluble by any heat-treatment. As a matter of fact, they form a eutectic which melts at relatively low temperatures. In a research published in the *Zeitschrift für anorganische und allgemeine Chemie*, vol. 118, p. 55, I stated that the melting point of this eutectic in chromium steels lies at about 2,100 deg. F. (1,150 deg. C.) and in tungsten steels as low as about 1,940 deg. F. (1,060 deg. C.). A ternary eutectic exists in high-speed steels containing chromium and tungsten, and it is evident that the eutectic is melted after a careless high heat and squeezed out by subsequent forging. In Figs. 10, 11, 13 and 14 of Mr. Weitzenkorn's notes such a fusion

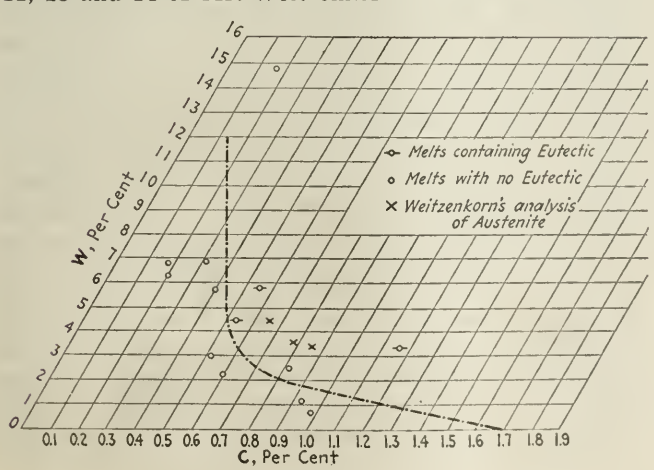

FIG. 1. SOLUBILITY LINE FOR Fe: W: C ALLOYS

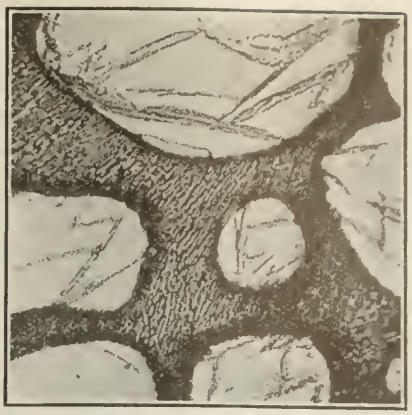

FIG. 2. CARBIDE MASS IN STEEL CONTAINING 1.90 PER CENT C AND 10 PER CENT W. ETCHED WITH HOT SODIUM PICRATE. × 555

is evident: the great freedom of the "eutectiform" carbides may be explained in this way.

Another result of my research was the approximate determination of the solubility line of carbon in chromium and tungsten steels—i.e., the line in the ternary diagram where the eutectic appears first. Fig. 1 shows that this line agrees fairly well with the results in Table II of Mr. Weitzenkorn's article. Crosses represent the chemical analysis of solutions he obtained after removing carbides from the austenite.

The structure to which the carbides revert on being heated to the melting point may be explained in another way, if we assume that the eutectic forms a series of "wires." On the left end of Weitzenkorn's Fig. 13 the "wires" are cut longitudinally and appear as narrow bands, but in the middle they are cut across; therefore the wires appear like spheroidal carbides. Massive carbides shown on the right end of Fig. 13 likewise would show this network if the sample were etched with hot sodium picrate. Fig. 2 shows such a carbide mass etched with sodium picrate in a tungsten steel containing 10 per cent W and 1.90 per cent C.

Düsseldorf, Germany. DR. K. DAEVES.

Electric Furnace Melting

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to the letter of Henry Traphagen in the issue of March 22, I was glad to note that the editor added a note to correct the erroneous impression conveyed as to limitations of the process.

We have all been too prone to leave uncriticized the impressions which seem to exist regarding the phenomena attributed to electric heat, when it should be considered simply as a means to an end. As you have so well stated in your editorial, the electric furnace permits the metallurgist to make use of slags for refining purposes which would be impossible to maintain by any other method of heating.

It is unfortunate that on account of the possibility of producing steel in the electric furnace equal in every way to the quality of crucible steel, we have not only compared the two grades of steel, but also the two methods of production and have tried to show points of similarity. To my mind the electric furnace process could better be compared with open-hearth practice, which it closely resembles in many important details, but which it excels on account of its greater flexibility and more accurate control of reactions.

Like the open-hearth, we have to deal with a large

mass of metal and we are constantly observing slag conditions. The entire success of the process, in fact, with exception of temperature, is due to maintaining a proper slag. The chief difference from the open-hearth bath is the advantage attained by the possibility of working with a reducing slag.

Probably one reason for many failures of electric melting has been the generally accepted idea that a crucible melter should be selected to do the melting. Far better success would have been had with an open-hearth man, if one took pains to show him the function of a reducing slag and instructed him how to maintain it. The study of slags is an old problem to him, while with the crucible melter it is a mystery from the start. On the other hand, there is little doubt as to the advantage of having a man familiar with crucible practice to take charge of the pouring, which in itself is an exceedingly important operation.

As to the points made in the letter in regard to impossibility of making good steel from poor grades of scrap, the writer again has been influenced by crucible practice. It is possible to make an excellent grade of steel from low-grade scrap in the electric furnace, just as much so as in the open-hearth in fact; but it is usually not advisable to do so, as the additional cost of current due to the extra time required more than offsets any saving there would be in the price of the scrap.

As to the reference to porous castings made by the electric process, an examination of the melting logs will probably reveal as the outstanding feature a very rapid production of heats. It is of course very desirable to use current for as short a time as possible and to get a high rate of production, but it is considerably more important that the heat should be properly killed before tapping, and this usually requires quite a little time to get correct conditions.

This is perhaps the reason why aluminum is used so freely. But it should not be overlooked that a small amount of aluminum is a good thing to make absolutely sure that the deoxidation has been complete. It has been common practice for many years not only in open-hearth steels but in many plants producing crucible steel to introduce a few ounces for each ingot.

The steel-casting organization has many conditions to meet in order to produce sound castings. It is necessary to have not only a quiet steel, but, what is just as important, properly vented molds. The production of steel castings by an organization not thoroughly familiar with all the details of production is a most hazardous undertaking and accounts for a very fair percentage of failures in this industry.

The electric furnace is a wonderful addition to the working tools of the metallurgist and already has made possible the solution of several important problems. The future will no doubt witness a very great development directly attributable to its use.

New York City. W. H. KEEN.

To the Editor of Chemical & Metallurgical Engineering

SIR:—Mr. Traphagen, in his letter in your issue of March 22, 1922, infers that certain faults exist in electric furnaces. He should, to the extent of his ability and belief, explain the redeeming features, provided there are any. We know the electric furnace possesses many of the latter.

Unquestionably, a "cycle of ups and downs" must be traversed by any scientific innovation before it arrives at its real field of application (and the latter is generally found to be limited). The electric melting furnace has not yet been stabilized in its operation or uses. "Wild advertising" of impossibly broad fields of application has doubtless contributed to the damage, but experience has led to the belief that this has been of small significance as compared with another underlying cause hitherto rarely mentioned.

Since the first commercial application of electric furnaces, competition among so-called furnace manufacturers, instead of leading to ultimate stability in methods, recommended applications, etc., really brought into existence "furnaces" not worthy of the name. The performances of these, most naturally, detracted from the exceptionally few that were deserving of serious consideration. Furthermore, the comparative ease with which successful operation can be obtained from a "crippled" furnace installation bears out the contention that the element most damaging to the industry is the fact that the expense for engineering on the job is usually incurred at the wrong time—namely, after the furnace was installed and operated.

Where Mr. Traphagen states that the electric furnace is a "good nurse for healthy material" only, the term "healthy" should be explained. If "healthy" is intended to exclude cheap scrap, the statement is entirely misleading. To prove this, we would call attention to the following typical costs of foundry steel in the ladle:

I—CONVERTER

1,000 lb. low-phosphorus pig	$21.50
1,000 lb. low-phosphorus and sulphur heavy scrap	7.25
333 lb. coke	1.17
20 per cent melting and converter loss	5.74
Ferro-alloys	1.60
Cupola refractories	.80
Cupola power and labor	1.25
Converter refractories	1.00
Converter power and labor	1.00
Cost per ton	$41.31

II—OPEN HEARTH

1,000 lb. bessemer pig	$13.50
1,000 lb. low-phosphorus and sulphur heavy scrap	7.25
6 per cent melting loss	1.25
60 gal. oil	6.00
Labor (furnace only)	1.00
Ferro-alloys	1.40
Refractory repairs	.60
Cost per ton	$31.00

III—ELECTRIC FURNACE

1,500 lb. steel turnings	$4.88
500 lb. foundry returns	3.62
3 per cent melting loss	.27
14 lb. electrodes	1.12
Refractory repairs	.40
Labor (furnace only)	1.00
Ferro-alloys	.50
Electric power	8.25
Cost per ton	$20.04

Costs are of course based on continuous operation.

Certainly there is no wonderful cleansing power in electric heat. But with a quarantine effectively established against outside "poisons," why cannot those inside the furnace be easily removed, if the furnace is treated as a "mere crucible"? Any temperature-time cycle is possible, permitting the use of as few or as many cleansing fluxes as may be required, and in any sequence. Appreciation of this comes from a detailed analysis of typical, successful practice. The value of being able to hold a neutral atmosphere may appear to be a good point about the electric furnace, but is its importance realized until investigation discloses just what can be done in a neutral atmosphere? One thing alone which is required for successful results and which is particularly a feature of electric furnaces is the ability to supply all of the oxygen used in the removal of deleterious elements and impurities in the solid form.

A discussion of this one item would require far more

space than the present article can be allotted. Could I suggest that better progress might result if we, rather than harshly condemn the electric furnace,

(1) "Jog up" the refractory manufacturers, to keep less than 10 years behind furnace advances.

(2) Eliminate inherently bad furnace designs from the field—regardless of patents or "right to exist."

(3) Utilize sufficient engineering on all installation.

(4) Cut out "wild advertising" to the effect that the electric furnace can do everything.

(5) Endeavor to supply the electric furnace, which is a valuable asset to industry, only to those capable of properly applying it, and see that they can get competent operators. C. A. BIRD.

Sessions Engineering Co.,
Chicago, Ill.

To the Editor of Chemical & Metallurgical Engineering

SIR:—We have noted in your issue dated March 22 a letter from Mr. Traphagen on the electric furnace. It occurs to us that there are certain statements made in this letter which are of a very sweeping nature and appear to require correction.

Mr. Traphagen proceeds to disregard the question of phases, single and multiple arcs, arrangement of electrodes, and electrical systems. We would point out that the selection of the correct electrical system is the secret of the commercial success of an electric furnace installed for any particular process.

Mr. Traphagen inquires what wonderful cleansing power there can be in electric heating, which seems to us to indicate that he has entirely overlooked the fact that the basic lined electric furnace has no equal for the purification of common raw materials, or that the metallurgist may use slags of varying composition so as to make use of varying reactions at will, and that he has not to cope with contamination of the steel from impurities brought in by furnace gases. It may, therefore, be said that the great advantage of electric heat is really the entire absence of contaminating impurities.

In modern designs of furnaces an almost perfect air seal may be obtained by the use of specially designed furnace doors which automatically seal themselves on being lowered into position. Modern electric furnaces are fitted with extremely efficient electrode economizers which surround the electrodes at the point where they pass through the roof. Flame-muffling devices are also fitted to these economizers which also prevent considerable losses of heat.

We would like to point out that the electric furnace can deal with a far greater proportion of rusty or oxidized material than other processes, the only objection to a great proportion of rusty material being the consequent wear and tear upon the dolomite hearth, which of course would apply to any other basic process. Also it is a well-known fact that electric steel is surprisingly free from occluded gases.

We would like to dispute the statement as far as electric furnace practice in Europe is concerned that foundries melting with electricity are particularly liberal with aluminum when casting the metal. This is purely a question of skilled metallurgy.

We are quite in agreement with your note at the bottom of Mr. Traphagen's letter, but we are certainly of the opinion that electric furnace makers in America will be in a position to disprove some of Mr. Traphagen's statements. ELECTRIC-METALS LIMITED,

London, England. By H. NEEDHAM.

Purple of Cassius Found in Bomb Washings

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the paper by H. L. Olin and R. E. Wilkin, of the Department of Chemistry, State University of Iowa, Iowa City, Iowa, on "The Effect of Bomb Corrosion on the Accuracy of Calorimetric Determinations," published in CHEMICAL & METALLURICAL ENGINEERING of April 12, 1922, the authors reached the conclusion that nickel was not a suitable metal with which to line the bombs. They demonstrated by experiment that nickel linings gave an error of 1.96 per cent up to 2.35 per cent, and recommend the use of some other metal better able to resist corrosion.

The writer has been using a calorimeter in which the linings were copper shells, heavily gold plated. It would appear that with this lining no corrosion could occur, since gold is resistant to the dilute acids formed by combustion—viz., sulphuric and nitric. But it is surprising to note that about half of the samples submitted for examination by this laboratory show that "purple of Cassius" is formed in the residues from the bomb washings, which are collected in water, preparatory to determining their sulphur content. The samples are of bituminous coal, mined principally in Pennsylvania and West Virginia. The purple pigment is rather deep in color in some coal samples, and in others it is not found. Its presence apparently indicates that the gold lining is slowly attacked during combustion of bituminous coal, although it is difficult exactly to account for its formation. The subject is open to some speculation and it may be possible that the small amount of potassium and sodium contained in the mineral matter of the coal, in the presence of the iron from the ignition wire and the nitrogen of the coal, forms alkali cyanides, which attack the lining.

It is interesting to observe that this purple of Cassius usually passes the first filtration and is precipitated with the barium sulphate in the determination of sulphur, giving a gold lake which is of a light violet color. Only a very small amount of gold is lost, however, since this lining, after about 1,500 determinations, is still in good shape and is not worn through to the copper. It is evident from this experience that the selection of an insoluble lining for bomb calorimeters is a difficult matter. Gold-plated linings are certainly a great improvement over nickel, but apparently even gold linings are subject to some corrosion, though very slight.

Electrolytic Iron a Commercial Product

On page 639 of our issue for April 5, 1922, a footnote to Mr. McMahon's article on "The Manufacture of Electrolytic Iron" makes reference to a previously published article by Bradley Stoughton on "Electrolytic Iron a Commercial Product." The latter article appeared originally in *Iron Age*, Jan. 5, 1922, and credit should have been given that publication, since CHEMICAL & METALLURGICAL ENGINEERING merely reprinted it by permission.

Concentrating Dilute Nitric Acid Solutions

In the article on "Concentrating Dilute Nitric Acid Solutions," by Clifford D. Carpenter and Joseph Babor, in our March 8, 1922, issue, the heading over the third column in Tables I, II and III should have been "Grams" instead of "Per Cent," as printed.

British Chemical Industries

From Our London Correspondent

London, April 16, 1922.

BUSINESS in chemicals and fertilizers is better than for some time past and prices are well maintained except as regards soda ash and chloride of lime, for which substantial reductions have been made by manufacturers. The most significant feature is the apparent absence of complaints or grumbling as to the state of trade—a sure sign that good business is being unobtrusively transacted and that the forward position is considered favorable. Even the recent depreciation in the mark and the revisions made in the safeguarding of industries act have not affected prices. The demand for fertilizers is still quite phenomenal and is partly due to the fact that buyers held off until the last moment in the hope of obtaining more favorable prices. Superphosphate is in strong request, while sulphate of ammonia is almost unobtainable. The market in coal-tar products is at last improving and cresylic acid is particularly firm.

Official Report Expected on Low-Temperature Carbonization

It is understood that the Fuel Research Board of the Department of Scientific and Industrial Research is about to publish a voluminous report on the experimental and technical development of low-temperature carbonization, and that the full results obtained at H. M. Fuel Research Station will be discussed at length. A preliminary report was issued by the board over 3 years ago and it is felt that some of the information which had accumulated was held back too long and to the detriment of those concerned with the commercial development of the industry. Low-temperature carbonization propositions have always been regarded with scepticism in this country and now that several systems are within measurable distance of success, a stimulus has been given to high-temperature carbonization by the researches of Messrs. Sutcliffe and Evans, who showed that a free-burning smokeless fuel can be obtained if the coal is briquetted under special conditions before carbonizing. It is stated that only 12 cwt. of the new fuel is required to produce 1 ton of pig iron.

Rival Low-Temperature Systems Discussed at Cardiff

The South Wales Institute of Engineers held a symposium at which almost every system except the "coalite" retort was discussed. The Nielsen system of carbonization in a rotary retort using the sensible heat in producer gas generated by part of the resulting semi-coke is of particular interest[1] and a large plant is under construction for India. The Fusion Corporation's report is also noteworthy for its simplicity, low cost and prevention of scale and "balling." One consequence of progress in this type of plant is renewed interest in oil shale retorting proposition, it being now realized here as in America that shale oil will play its part in supplying the ever-increasing demand for oil fuel and motor spirit. The Scottish shale industry was mainly dependent upon its revenue from sulphate of ammonia and paraffine wax, but the commercial future of shales and torbanites found in Great Britain, Australia, Esthonia and elsewhere will depend not only on successful methods and research but upon educational work and propaganda in regard to the marketing of the products. Reference has been made in these notes to English Oilfields, Ltd., a company which has so far been unsuccessful on account of the high sulphur content of the oils obtained and on account of retorting difficulties. There are indications that both obstacles will shortly be overcome.

[1] See *Engineering*, March 25, 1922.

A New Buyer's Guide for the Chemical Trade

S. Davis & Co. are preparing for issue in July a chemical trade directory on somewhat original lines, which may be more truly representative and reliable than those previously obtainable. The normal practice has been to obtain payment not only for the insertion of names of firms but also to make a fairly substantial charge for supplying the directory itself to users, and the result has been that chemical directories have circulated mainly among the advertisers themselves. It was also found that under some classifications either some of the largest suppliers had not thought it worth while to advertise or else the list was chiefly composed of unimportant manufacturers or agents and traders. The present buyers' guide is to have a guaranteed circulation of 10,000 copies among actual buyers, will be issued free of charge and a certain number of entries will be given free to each manufacturer whether he advertises or not.

Automatic Electric Welding

The Cyc-Arc process, which is being developed by Handstock, Ltd., is attracting considerable attention not only in the shipbuilding industry but also for chemical and metallurgical equipment and for other special applications. By this process metal studs, rods and tubes can be automatically and directly welded on to sheets, tubes, forgings, etc., by electrical means and without the use of fluxes. The process is applicable not only to brass and other alloys welded on to iron and steel, but recently it has also been possible to weld high-speed tool steel tips on mild steel shanks, thus effecting a considerable saving in the cost of lathe tools. The strength of the weld is equal to or greater than the original strength of the material and large studs can be welded at the rate of about forty per hour. A process of this kind should prove useful in cases where the maintenance of gas and water tightness is essential and it therefore has possibilities in connection with the design and rapid construction of chemical plant.

General Notes

Among recent decisions in the safeguarding of industries act may be mentioned that of liquid sulphur dioxide, which was held to be free of duty because no greater degree of purification was necessary than if the gas had been used in the manufacture of sulphuric acid by a catalytic process. An unsuccessful attempt was also made to remove the duty on mucic acid on account of its impending manufacture on a large scale by the Acree process of the International Products Co., at Eureka, Mont. The proposal to remove the duty from synthetic camphor, chiefly used by the British Xylonite Co., is still under consideration. Rumors persist regarding the financial reconstruction of the British Cellulose & Chemical Manufacturing Co., and although these have been officially denied, it is fully expected that an arrangement with a Continental firm will shortly be made. Sir Ernest Rutherford is to be the new president of the British Association.

A PORTION OF BALTIMORE'S SKYLINE

Baltimore Meeting of American Electrochemical Society

Report of Technical Sessions Comprising a Symposium on Electric Cast Iron and One on Electrodeposition—Honorary Membership Conferred on Dr. Carl Hering—Dr. C. G. Schluederberg Elected President—Fall Meeting at Montreal Sept. 21-23

THE American Electrochemical Society held its forty-first general meeting at Baltimore, April 27 to 29 inclusive. It was one of the very best meetings the Society has ever held. The attendance was exceptionally good, the technical sessions were very well conducted, there being an unusual amount of animated discussion. The social features were most attractive and enjoyable due to the untiring efforts of the local committee under the chairmanship of William H. Boynton.

Thursday morning and afternoon were given over to the symposium on Electric Cast Iron, one of the best symposiums ever held by the Society, being attended by many engineers of international repute who took very active part in the discussion. This symposium was reported at length in our last issue.

Friday Sessions

A Plea for Rational Interpretation of Hydrogen-Ion Measurements

Dr. William C. Moore of the Research Laboratory of the U. S. Industrial Alcohol Co., Baltimore, reported that he had found that in many biological systems hydrogen-ion regions are of more importance than actual hydrogen-ion concentrations. Thus, invertase has a flat maximum of activity in the range for $[H_+]$ 1×10^{-4} to 1×10^{-5}, and, concurrently, fermenting molasses mashes show within this range no relation between hydrogen-ion concentration and yield of ethanol. He made a plea to express hydrogen-ion concentrations in any one set of measurements in terms of a common denominator instead of as pH values, which for chemical work sometimes seem inconvenient.

Discussing Dr. Moore's paper, Clarke E. Davis of the Research Laboratory of the National Biscuit Co. showed curves based on actual titration of phosphoric acid. The second end point, contrary to Clark,[1] was found to be more than twice the first by an appreciable amount. This result is not accidental, but has shown itself in repeated titrations and by different investigators. Mr. Davis very much favored the Sorensen method of expressing results. Dr. Blum of the Bureau of Standards emphasized that usually the intensity factor was much more important than the quantity factor. C. P. Madsen said that in the case of nickel-plating solutions it was difficult to obtain concordant pH values.

Electrolytic Copper and Zinc

"The Conductivity of Copper Refining Electrolytes" was the subpect of a highly interesting paper by Prof. E. F. Kern and M. Y. Chang of Columbia University. The specific conductivities of solutions of sulphuric acid, copper sulphate, and of mixtures of sulphuric acid and copper sulphate were determined at 25 deg. C., 40 deg. C. and 55 deg. C. The concentrations of the solutions were 5, 10, 15 and 20 grams per 100 c.c. The effects of the presence of arsenic, nickel sulphate and ferrous sulphate upon the conductivity of a copper-refining electrolyte were determined, showing that the presence of arsenic does not appreciably depress the conductivity, whereas the presence of nickel sulphate and of ferrous sulphate depresses the conductivity very much.

The conclusions drawn from the results of these determinations are:

(a) The copper content of refining electrolytes should be kept between 30 and 35 grams per liter (approximately 120 to 140 grams $CuSO_4.5H_2O$) and the free sulphuric acid as high as economy permits up to 175 grams per liter. With higher free sulphuric acid content the solubility of copper sulphate decreases

[1] "The Determination of Hydrogen Ions," p. 32.

rapidly, and also the added increase in conductivity with more concentrated sulphuric acid is relatively not so rapid.

(b) Maintain the temperature of the electrolyte as high as economy permits. The economical temperature limit seems to be 55 deg. C.

(c) Keep nickel and iron content of the electrolyte as low as possible, as the presence of sulphates of these metals greatly depresses the conductivity of the electrolyte.

Lawrence Addicks of New York, in commenting upon the paper, felt that it was important to take into account the adsorption factor, which may change the results found by the authors. Further investigations along the lines pursued by Dr. Kern and his co-workers seemed desirable.

"Electrolytic Zinc and Hydrogen Overvoltage" was investigated by U. C. Tainton of the Bunker Hill & Sullivan Mining Co. of San Francisco.

If there be one factor in the production of electrolytic zinc which would seem to be firmly established, it is that relating to the necessity of a pure electrolyte. From Mylius and Fromm onward, the most gratifying unanimity prevails in the literature in this regard. Laist says, "Pure solution is the greatest single factor in the production of electrolytic zinc." Hansen, "Impure solutions invariably yield imperfect cathodes." Hall states, "The requirement, and I use it in the singular, for zinc electrolysis, is zinc sulphate, and zinc sulphate only." Siemens and Halske, "Every other metal and even carbon must be completely excluded."

These are high ideals. The production of pure zinc sulphate solution is no easy matter.

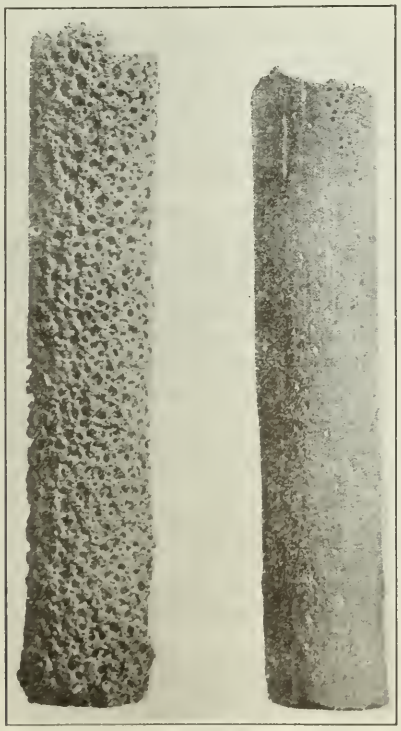

FIG. 1. × 1.5

Left—Zinc deposit from well purified solution, almost free from colloid, showing effect of adhering hydrogen bubbles.
Right—Zinc deposit from same solution but with trace of gelatin added.

Mr. Tainton found the following conditions indicated as favorable to the production of good zinc deposits from impure acid solutions: 1. Highe urrent density. This gives high overvoltage of hydrogen. 2. High electrolyte conductivity. This permits a low potential gradient and restrains "trees" which lower current density. 3. Diminished interfacial tension at contact surface of cathode and electrolyte. This gives a small contact angle, preventing the hydrogen bubbles from adhering to cathode. 4. Rapid upward movement of electrolyte past cathode surface. This usually arises automatically if sufficiently high current densities be employed. 5. Presence of some addition agent which will restrain crystalline growth of cathode deposit and raise overvoltage of impurities.

Commercial electrolytic zinc is deposited from solutions which, from an electrochemical viewpoint, are to be regarded as necessarily impure and containing free acid. The continued deposition of metallic zinc from such solutions depends on the maintenance of a high hydrogen overvoltage at all points of the cathode surface. This is attained by the maintenance at all points of a substantial current density, which, in turn, depends largely on the smoothness of the deposit. By sufficiently increasing the current density the hydrogen overvoltage for all metals examined (lead, cadmium, copper, iron, nickel, cobalt, antimony) may be made to exceed the potential of zinc on the hydrogen scale. This does not accord with figures obtained by the commutator method of measuring the variation of hydrogen overvoltage with current density, and it is believed that this method is unreliable. The overvoltage of the alloys examined lies between the overvoltages of their constituents. In the case of zinc deposits containing impurities, the overvoltage is very high as long as the zinc surface is clean and growing. However, the overvoltage of an impure, corroded zinc surface is found to be very low, and so once corrosion begins (at a point of low current density), it tends continually to spread. The function of colloidal matter such as gelatin in the electrolyte is to raise the overvoltage of hydrogen. It also lowers the contact angle of the hydrogen bubble, thus preventing adhesion of bubbles to the cathode surface. It tends to restrain crystalline structure of the deposit. All these factors tend to maintain smoothness of deposits. Practical work indicates optimum conditions to be a free acid concentration of about 250 to 300 grams per liter with a current density of about 100 amp. per sq.ft., and the presence of a minute quantity of gelatin or similar colloidal matter in the solutions.

Experiments With a.c. in d.c. Electrolysis

W. B. Jones of Buffalo submitted a detailed account of an investigation extending over several years. Potentiometer measurements of the potential difference of a lead cathode and a hydrogen electrode were made over a cycle of 0.04 second, during which combined alternating and direct currents flow through the electrode. This potential was plotted against the current flowing, and a graphic correction made for the true overvoltage. When plotted against coulombs, interesting results were found. These indicate the formation of stable and unstable compounds, as films on the electrode, as the cause of overvoltage. Measurements with intermittent direct current give the approximate stability of the lead hydride when the current is cut off. The potential of the hydride drops in this case about 0.6 volt in 0.08 second. Indications are that there is a lower hydride that is quite stable. An approxi-

mate calculation of the higher hydride formula gives about PbH_3.

The maximum overvoltage attained during cathodic action is only slightly lowered by superimposing increasing amounts of alternating current upon the direct current.

Electrolytic Corrosion

Dr. Robert J. McKay of the Mellon Institute studied "The Corrosion by Electrolytic Concentration Cells." He found that the corrosion could be very much accelerated in the case of a homogeneous metal in acid solutions, due to differences in concentration of dissolved materials in the solution. Copper is dissolved from Monel metal tie rods of pickling tanks due to leaks between the timbers.

A cell was set up with Monel metal electrodes in sulphuric acid (60 grams per liter), the solutions around the two electrodes being separated by a porous cup. The electrodes were connected in external circuit through a galvanometer. When the solution around one electrode was stirred and the other permitted to remain quiet, a deflection of the galvanometer was obtained showing a flow of current through the cell, the agitated electrode being the anode. The current continued as long as the stirring was kept up. If the solution at the other electrode was now stirred and that first stirred permitted to come to rest, the current was reversed. It was also found possible to produce a current with both solutions agitated, by making the agitation at one electrode more violent than at the other. The direction of the current was always such that the more violently agitated electrode was the anode.

Dr. W. C. Moore pointed out that in the past too little attention has been paid to the dissolved air in the acid electrolytes. Very likely this dissolved air played a very prominent rôle in effecting the speed of corrosion. Referring to Dr. McKay's observation on the effect of stirring, Dr. Fink cited the problem of finding a suitable metal or alloy for acid pumps. An alloy may be very resistant to corrosion when quietly suspended in an acid solution and yet this same alloy is a complete failure when used in a pump for this same acid solution. Unfortunately, many of our investigators draw conclusions as to the merits of an alloy without submitting it to actual practical tests. Dr. C. J. Thatcher of New York described tests made on platinized electrodes. The potential readings were very largely dependent upon the rate at which the gas, O or N, was supplied to the electrode. Burnham E. Field suggested that some of Dr. McKay's results might be interpreted by taking into account the difference in oxygen concentration of the solution directly in touch with the tie rod and that some distance away. George B. Hogaboom said that in investigating the speed in pickling solutions he had obtained concordant results by resorting to the "alternate in and out" method of testing samples—that is to say, exposing the samples alternately to the solution and then to the air.

The Effect of Impurities on Storage Batteries

Mrs. Helen Gillette Weir of the Prest-O-Lite Co. gave a highly interesting account of the results of her investigations on the effect of impurities in the sulphuric acid of batteries. The presence of certain amounts of impurities in the electrolyte of a storage cell was studied to ascertain the effect on the electrical performance of the cell. The extent of the injury was determined by comparison of the electrical characteristics of the cells before and after contamination and by further comparison with normal cells included in the same series of tests. Of the metals tested only manganese and platinum produced intense injury when present in minute quantities. With these two exceptions, none of the impurities tested had a lasting effect on the cell voltages or on the ampere-hour capacity of the charged battery. In various amounts certain of the impurities were found to be injurious, either by increasing the rate of self-discharge or decreasing the life of the plates. Zinc, nickel and tin in small percentages were not detrimental to any of the electrical characteristics. The results of these tests indicate that, contrary to the general belief, most of the common metals and acids may be present in appreciable quantities without causing serious injury to the cell.

The Technical Man as a Citizen

Presidential Address by Acheson Smith

We expect shortly to print this admirable address in full and give here only a few excerpts. "This is the age of the engineer, but it is possible that we do not understand the full significance of that phrase. The present advanced state of civilization is mainly due to the technical men. In view of what has been accomplished by the engineer, it may sound strange to say that he is seeking recognition, but such is the case. What can the engineer do to procure such recognition? The leaders in the country are those who do a citizen's duty and a little more, over a term of years, and as a result find themselves the influential men in their community. Under a system of government where the illiterate and men of low ideals have an equal voice with the educated and men of high ideals, the only thing that can prevent liberty from destroying itself is intelligent leadership. Here is an opportunity for the engineer."

Saturday Sessions

Hydrogen and Oxygen

The first paper of the Saturday morning session was entitled "The Production of Hydrogen by the Use of Silicon and Sodium Hydroxide." The author, E. R. Weaver of the U. S. Bureau of Standards, described the generation of hydrogen by the "silicol" process, which has been found very adaptable for military and naval purposes. The non-combustibility of the materials used insures safety of transportation. The rate of reaction of ferrosilicon with sodium hydroxide, in the subsequent generation of hydrogen, depends upon the composition of the material, its fineness. the concentration of the sodium hydroxide and dissolved silicon in solution, and the temperature. The plant, of a small size, low cost and of high productive capacity, consists essentially of three parts: The solution tank, the generator and the washer. The merits of the process and comparative cost figures for materials were given.

The only considerable disadvantage of the method is its cost. With 85 per cent ferrosilicon costing $200 per ton and sodium hydroxide costing $4 per 100 lb., the cost of materials for 1,000 cu.ft. of hydrogen at 60 deg. F. and 30 in. pressure will be $4.60 for ferrosilicon and $1.50 for sodium hydroxide, a total of $6.10. When transportation and handling charges for the materials are added, the cost for materials alone is not likely to be less than $7 per 1,000 cu.ft. The labor and

capital charges on any plant which is used steadily become negligibly small. In any case they will probably be less than for any other method of generating hydrogen.

William G. Allan, research engineer of the Toronto Power Co., next presented a detailed account of the "Electrolytic Generation of Hydrogen and Oxygen, With Special Reference to the Utilization of Off-Peak Power." Mr. Allan discussed at length the economics of the problem and showed a series of curves which greatly facilitate cost computation. The utilization of "off-peak" power, for the purpose of generating these gases at cheap prices with a view to their use in large quantities in the chemical or other industries, was advocated. Special mention was made with a brief description and some illustrations of a new type of electrolytic cell, designed and developed by Mr. Allan. Basic constants and data used in calculations were given, and comparisons of the chief characteristics of the new cell with those of other existing types were submitted.

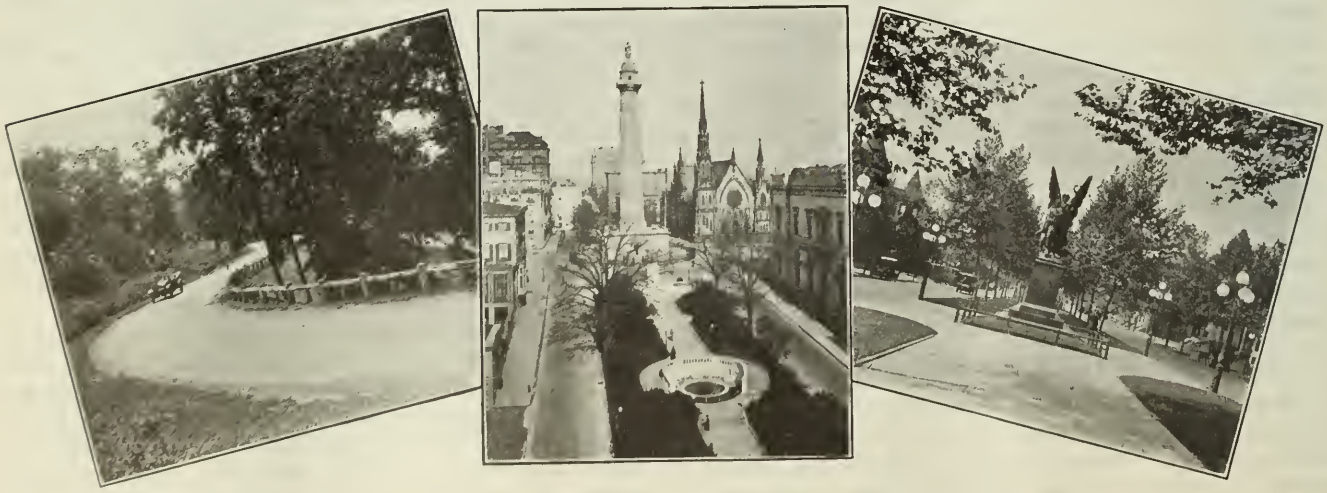
The Allan cell is adapted to operate under widely varying conditions of current density per square inch of projected electrode area, without too great a sacrifice of energy efficiency. It is thus adapted for operation at different rates of gas production, according to the cost of power at any particular time of a 24-hour day, during which it is conceivable that a power consumer has contracted for power under two or more different rates. The higher the rate of gas production the less the influence of the fixed charges in the total cost of the gases, while depreciation does not increase at a rate which is proportionate to the rate of gas production. As a result, at high current densities, the cost of power becomes the major item in the total costs of the gases, and where power is cheap, as in the case of "off-peak" power, the gases may be produced very cheaply, and many processes which up to the present have been excluded from consideration now come at least within the range of possibility, while others are definitely placed in the class of commercially feasible processes. Mr. Allan showed the influence and relative importance of the various items entering into the costs of the gases, and finally mentioned the many present and future possible uses of the two gases.

V. T. Stewart of Montclair, N. J., pointed out that the usefulness of hydrogen is greatly hampered by its outstanding property—namely, being the lightest known substance. He referred to the various applications of hydrogen, among others the use of the gas for certain metallurgical operations. Here hydrogen is of distinct advantage on account of its comparative inertness. In the annealing of ingot iron, the presence of an atmosphere of hydrogen modifies the properties of the metal enormously. An atmosphere of hydrogen is of distinct advantage in the cooking of certain kinds of paper pulp. The resulting stock is stronger and requires less bleach. Dr. Fink emphasized the importance of hydrogen as a reducing agent in many metallurgical operations. The high cost of electrolytic hydrogen as compared with coke or other carbonaceous reducing agents was often more than offset by the much lower operating and maintenance charges; due to the low temperatures at which many of the hydrogen reductions can be carried out, the furnace construction is simpler and less expensive and the labor costs are small.

Dr. Carl Hering of Philadelphia described experiments he carried out, electrolyzing acidulated water in a bomb. Pressures of about 34 atmospheres were attained. The potential dropped to 0.3 volt and apparently the gases at the electrodes were not evolved according to Faraday's law. Dr. Fred T. Kaelin of the Shawinigan Water & Power Co. emphasized the importance of Mr. Allan's contribution and mentioned many new uses for the gases H and O.

The Radium Content of Products of Low Activity

Dr. Victor F. Hess, chief physicist of the U. S. Radium Corporation, described a very ingenious but comparatively simple method he developed for the detection and estimation of radium when present at very low concentrations. Hess' method is a thousand times more sensitive than the best method known heretofore. When carnotite or other materials are filled into a space between two concentric spheres, the gamma ray effect in the center of the inner sphere can be calculated. This formula was taken as the basis of a direct method of determining the radium content of these substances. The samples were filled in wooden containers which were closed hermetically. The gamma ray electrometer was introduced into the center. The observed ioniza-



Photos by J. F. Hughes Co., Baltimore

VIEWS OF INTERESTING SECTIONS OF BALTIMORE

tion, expressed in absolute units (E.S.U.) reduced to normal pressure and temperature, multiplied by certain constants, gives directly the radium content per gram of material.

The method is sensitive enough to give correct figures for material with 10^{-10} grams radium per gram of material. It is very simple, and requires no chemical treatment of samples before the measurements.

The results on ore samples were compared with the results derived from the chemical analysis of the uranium content and were found to be in good agreement. In discussing Dr. Hess' paper, Dr. S. C. Lind, chief chemist of the Reno Station, Bureau of Mines, pointed out the great importance of possessing a method as sensitive as that devised by Dr. Hess. It finds practical application in the concentration of radium-bearing ores where chemical analysis and control fail. Furthermore the Hess method has a very wide application and does not require an expert, as in the case of the emanation method. Dr. Harlan S. Miner of the Welsbach Co. regretted that Hess' method was not applicable to thorium products.

Electromagnetic Motions in Electric Furnaces

Dr. Carl Hering discussed the new electromagnetic law he proposed some months ago. The new law is: In a system of electric current-carrying conductors any, and only such, mechanical motions of its conductors will tend to take place as will generate a counter e.m.f. somewhere in the electrical circuits. But whether or not this electrical version is the best one, the general law of nature on which it is based ought to apply to all electromagnetic systems as well, and it seems to follow in any case that our older restriction to only one possible force was unjustifiable. In general, according to the above law, any desired motion of the conductors (especially of the mobile liquid conductors or arc vapors in electric furnaces) can probably be produced electromagnetically by the current itself, if such a motion would produce a counter e.m.f. somewhere in the circuit, if the necessary freedom of motion exists, and if there is not also produced thereby somewhere else in the system an equal and opposite effect. The original source of energy must of course be able to provide the additional voltage to overcome this counter e.m.f.—that is, it must provide the energy for such motions. While theoretically there may be no limit to the intensity of the forces thus produced, in practice there is. A few pounds per square inch will, however, produce quite rapid motions of even heavy molten liquids. Strong forces require large currents, which tend to generate heat; such forces are, therefore, limited largely to furnaces in which this heat is useful.

Gas Pressures in Tungsten Vacuum Lamps

The Research Laboratory of the Westinghouse Co. has been studying the methods for the "Measurement of Pressures in Vacuum Type Electric Lamps." Dr. Duncan MacRae, research physical chemist, reported upon a new and simple method he devised for determining these low pressures.

The tip of the lamp is removed in an evacuated glass system by means of an iron plunger electromagnetically operated. The resulting pressure is measured with a McLeod gage and the pressure in the lamp before opening is calculated. The results of measurements on unflashed, flashed and life-tested lamps are given.

Dr. C. J. Thatcher, of New York, maintained that on the basis of his own experience red phosphorus does not combine with oxygen at very low pressures without "flashing" or ionizing the phosphorus. Accordingly the gradual rise in pressure after removing the tip cannot be accounted for by the reaction $2P + 5H_2O = P_2O_5 + 5H_2$. Dr. C. C. Paterson of the British General Electric Co., writing from London, suggested that this gradual rise in pressure was due to the formation of PH_3, on the basis of experiments carried out by his associates. "If Dr. MacRae's apparatus was not thoroughly dry before the tip of the lamp was broken, we should expect to find a generator of gas when it is broken." Dr. Paterson also emphasized the advantage of the Pirani over the McLeod gage.

Ortho-Amidophenol, Electrolytically Produced

The subject of organic electrochemistry has been interesting an ever-increasing number of members of the Society. Plans are under way for the formation of an organic electrochemistry division.

Oliver W. Brown and J. C. Warner, of the department of chemistry, Indiana University, investigated the commercial possibilities of the "Electrolytic Preparation of Ortho-Amidophenol."

All reductions of ortho-nitrophenol to ortho-amidophenol were carried out in caustic soda solutions and at a copper gauze cathode. Results of experiments show the effect of current density, concentration of caustic soda and ortho-nitrophenol in the cathode liquor, and temperature at different current densities on current efficiency and material yield. The quantity of amine produced was determined by a method involving diazotization with standard sodium nitrite.

As best conditions for the electrolytic preparation of *o*-amidophenol from *o*-nitrophenol in alkaline solution and at a copper cathode, the following conditions are recommended. Start the reduction with a cathode solution of 15 per cent NaOH containing 3 to 5 grams of *o*-nitrophenol per 100 c.c. Maintain a temperature slightly below the boiling point and use a current density of 10 amperes per sq.dm. When one-half of the *o*-nitrophenol has been reduced, add one-half the original amount of the nitro compound. After another such period, add a similar amount of *o*-nitrophenol. Continue the reduction with a current density of 10.0 amperes per sq.dm. until the concentration of *o*-nitrophenol has dropped to about 1.5 grams in 100 c.c., then lower the current density to 4 to 5 amp. per sq.dm. and the temperature to 60 to 70 deg. C. and continue the electrolysis until the concentration of *o*-nitrophenol has dropped to 0.8 gram per 100 c.c. Finish the reduction with a current density of 1 to 2 amperes per sq.dm. Under these conditions, a material yield and current efficiency of 97 to 99 per cent should be obtained.

Commenting upon Brown and Warner's method, Dr. C. J. Thatcher questioned whether it would be practical on a large scale, as it was very difficult to electrolyze at or near the boiling point. Furthermore, he knew of no diaphragm which would resist the destructive action of hot NaOH solutions for any length of time.

Electrodeposition of Metals

A very animated discussion was aroused by four papers dealing with electrodeposition. The first paper, by W. E. Hughes of London, was headed the "Idiomorphic and Hyp-idomorphic Structures in Electrodeposited Metals."

By idiomorphic structure is meant the structure

which results in a mass of rock or deposited metal when the crystals composing it have had the opportunity to develop their external forms freely.

By hyp-idiomorphic structure is meant the structure resulting from the fact that the component crystals (or the majority of them) have not had the opportunity to develop their faces and edges freely, but, owing to mutual interference, have been compelled to take their shapes from their surroundings.

It is suggested that these definitions are sufficient for indicative and descriptive purposes, though they may not be as exact as might be.

Microphotographs were shown of electrolytic copper, zinc and iron. One of the electrolytic iron photographs clearly demonstrated how upon increase in the free acid concentration of the electrolyte the crystal structure could be made to change from an idiomorphic to a fibrous one and then into a hyp-idiomorphic one by decreasing the acid concentration.

Briefly, the hyp-idiomorphic structure is that within the mass of deposited metal which corresponds to an idiomorphic structure on the surface. The former grows into, or becomes, the latter as deposition continually proceeds. The relation is analogous to that obtained between normal within and coarsely crystalline on the surface, or, again, between fibrous within and very finely crystalline, or apparently amorphous, on the surface.

"The Acidity of Nickel-Depositing Solution" was carefully investigated by M. R. Thompson of the Bureau of Standards. A simple method was applied to the quantitative measurement and control of the pH of nickel-depositing solutions by means of indicators. The pH characteristics of several types of nickel-plating solutions have been studied. Preliminary observations were made on the general effect of pH on the appearance and structure of nickel deposits and the range of pH used in commercial nickel plating was investigated. A plea was made for the inclusion of complete pH data in all future publications dealing with research on the electrodeposition of such metals as nickel, cobalt and iron.

Charles H. Proctor, of the Roessler & Hasslacher Co., heartily supported Mr. Thompson in his opinion that the pH values can be used as a control of nickel solutions. George B. Hogaboom, of the Scovill Mfg. Co., however, pointed out at length that the pH values were not always reliable and frequently very misleading. He found that pH readings are affected not merely by the hydrogen-ion concentration but also by the metal-ion concentration of the electrolyte. Two nickel sulphate solutions might give the same pH readings and yet their composition and the electrodeposits obtained be totally different.

Dr. E. A. Vuilleumier briefly described his contractometer[2]. A. K. Graham, of the University of Pennsylvania, commented upon the irregularity in the thickness of the deposit on the platinum plate of the contractometer and suggested that this irregularity might effect the bending of the plate. But Dr. B. E. Field of Niagara Falls maintained that such would not be the case. C. P. Madsen recited at great length the deceptive results obtained with the pH methods applied to nickel electrolytes. Impurities present in quantities as small as 1 part in a million were often enough to cloud the readings. Very much more important than the pH reading of a nickel electrolyte was a knowledge of the composition and properties of the anodes used. In defense of the pH method it was pointed out by Mr. Madsen and others that as a rule good and comparable results were possible with dilute solutions and not with concentrated solutions such as are used in plating operations.

Prof. W. G. Wood and T. Fuwa reported on an investigation carried out at the Massachusetts Institute of Technology on "The Throwing Power and Current Efficiency of Zinc-Plating Solutions." The subject is of great commercial importance. It was found that zinc-plating baths, the principal constituents of which are sulphate, fluoborate or zincate, show small throwing power, although satisfactory deposits may be obtained with sulphate baths when anode and cathode are plane and parallel to each other. Alkaline cyanide baths, having the composition

Sodium cyanide, grams	53.2
Zinc cyanide, grams	59.2
Sodium hydroxide, grams	43.8
Sodium carbonate, grams	9.5
Aluminum sulphate, grams	4.7
Lignol, grams	11.8
Water, c.c.	1,000

show high throwing power, moderately high efficiency, very low voltage and give continuously good results when operated under proper conditions. The proper conditions for operating the above alkaline cyanide bath continuously were determined and found to be as follows: C. D., 2 amp. per sq.dm.; temperature, 40 deg. C.; stirring, moderate; anode, composite of zinc and Duriron, the Duriron surface forming 30 per cent of the total anode surface. The use of an addition agent is necessary. Glue is fairly satisfactory, but "lignol" was found to be a better and cheaper material.

Mr. Hogaboom, in discussion, said that he, as a plater, interpreted the term "throwing power" to mean the ability of a solution to deposit metal in deep recesses. For example, certain nickel solutions will give a uniform deposit inside a shaving soap box (1 in. diameter x 3 in. deep) without an anode inside the box. Mr. Proctor found cyanide solutions better than sulphate solutions for zinc plating. Dr. Blum pointed out that there was a so-called primary distribution of the current which was practically the same for all electrolytes, no matter whether cyanide or sulphate. "Throwing power" refers to a deviation from this primary distribution. He felt that eventually we may be able to predict the throwing power of a solution on the basis of cathode potential current density and current efficiency of an electrolyte. Work along these lines is now being carried out at the Bureau of Standards. Copper cyanide is better than zinc sulphate. Agitation and heating of the electrolyte will decrease the throwing power. Mr. Proctor displayed an iron tube, about ½ in. in diameter, which had a uniform zinc plate on the inner wall. Mr. Hogaboom emphasized that with an electrolyte having good throwing power tubes would be plated evenly inside and out no matter how placed in respect to the electrodes.

Winnipeg as an Electrochemical Center

The concluding paper of the Saturday morning session was entitled "A New Hydro-Electric Power Development of Importance to the Electrochemical Industry," by M. C. Gilman of Winnipeg. An important low-cost hydro-electric power development is nearing completion in the Winnipeg district. Very soon there will be available 320,000 hp. and more than 250,000 hp.

[2]See *Mineral Industry*, October, 1921, p. 419; March, 1922, p. 109.

remaining for future requirements. The third plant, nearing completion, will represent an outlay of but $70 per horsepower, or decidedly less than at Niagara Falls. Raw materials for the production of abrasives, cyanamide, ferrosilicon, ferro-alloys, cobalt alloys, magnesium, aluminum, etc., are readily accessible. Copper and nickel deposits are plentiful. On one property 20,000,000 tons of this ore has been blocked out. Large deposits of gold-bearing molybdenite deposits have been located near High Lake. High-grade iron ore is also available within comparatively short economic rail haul.

Business Sessions

Dr. Hering Made an Honorary Member

At the meeting of the board of directors Dr. Carl Hering was unanimously elected an honorary member of the Society. Dr. Hering was one of the founders of the Society and has been one of the most active and loyal members ever since. He has a world-wide reputation as an electrical engineer. He was born in Philadelphia, March 29, 1860, and is a doctor of science of the University of Pennsylvania. He is a Chevalier Légion d'Honneur, past president of the American Electrochemical Society, of the American Institute of Electrical Engineers, of the Philadelphia Engineers Club and an honorary member of the New York Electrical Society. He has contributed lavishly to the scientific world and has published over 400 scientific and technical papers. He is the inventor of a number of electric furnaces and other apparatus. His "Conversion Tables" are an international handbook. His scientific interests are most diverse. He can discourse on the proper cultivation of mushrooms as freely as he can on the theory of Einstein or on the Steinmetz equations. The formal ceremonies, conferring the honorary membership on Dr. Hering, took place on the evening of April 27 at Johns Hopkins University, President Acheson Smith making the presentation.

CARL HERING
Honorary Member American Electrochemical Society

Joseph Richards Memorial Fund

Several members of the Society suggested raising a prize fund and devote the interest of it to the encouragement of original research and original contributions to the *Transactions* of the Society. A committee was appointed to investigate the matter and report back to the next board meeting.

New Subjects for Future Meetings

The following subjects were suggested for discussion at future meetings of the Society: For the fall meeting, Montreal, Sept. 21, 22 and 23. 1922, "Industrial Heating," which subject will be in charge of the Electrothermic Division, Bradley Stoughton, New York, chairman. The second subject for the Montreal meeting will be "Electrical Endosmosis," in charge of F. A. Lidbury, Niagara Falls. "Industrial Heating" will be largely concerned with the details in the construction and design of furnaces and ovens for low-temperature operation, such as are used in heat-treatment, glass annealing, ceramics, etc. The question of the selection of resistor, heat transfer, specific heat of materials, etc., will likewise be included. For the spring of 1923 meeting two subjects have been selected: "The Potential and Overvoltage of Aqueous Solution," in charge of Prof. W. G. Horsch, Massachusetts Institute of Technology; and "The Production and Applications of the Rarer Metals" (such as Zr, W, Mo, Ta, Co, Ti, etc.), in charge of the Electrothermic Division.

Election of Officers for 1922-1923

The new president of the Society is Dr. C. G. Schluederberg of the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa. Dr. Schluederberg was graduated from the School of Electrical Engineering of Cornell University in 1902 and in that year entered the employ of the Westinghouse Electric & Manufacturing Co., taking up the company's college graduate apprenticeship course. After a year in the shops, he was transferred to the Pittsburgh sales office. In 1905 he entered upon company research work, doing electrochemical as well as post-graduate work at Cornell University. He continued at Cornell until 1908, when he completed this work and was awarded the degree of doctor of philosophy and a degree in chemistry. He also spent some time abroad on special investigations and subsequently became associated with the Carnegie Steel Company in electrical and metallurgical work. In 1910 Dr. Schluederberg returned to the Westinghouse company as commercial engineer in the supply department and from 1911 until 1915 was in charge of switchboard work. Since 1915 he has been assistant to the manager of the supply department, in charge of various phases of its work, including central stations, railways, syndicates, licenses and educational work. He is a member of a number of engineering and other societies and has been particularly active in the American Electrochemical Society. He has published a number of articles covering original research work on electrochemical activities and developments.

The new vice-presidents are H. C. Parmelee, editor of Chem. & Met.; Albert H. Hooker of Niagara Falls, and W. S. Landis of the American Cyanamid Co. The new managers are A. T. Hinckley of the National Car-

bon Co., W. M. Corse of the National Research Council, Washington, and William Blum of the Bureau of Standards. The new treasurer is F. A. Lidbury of Niagara Falls and the secretary is Colin G. Fink of 101 Park Ave., New York City.

Organization of the Divisions of Electrothermics and of Electrodeposition

At a meeting of the Electrodeposition Division plans were made for future meetings, members of the Council were selected and the following executives were inducted into office: Chairman, Bradley Stoughton, 10 East 44th St., New York; vice-chairman, John A. Mathews, Crucible Steel Co.; secretary-treasurer, Colin G. Fink, New York. Directors: George K. Elliott of Cincinnati, James H. Parker, Wyomissing, Pa., W. J. Priestley of West Virginia, and Dorsey A. Lyon of the Bureau of Mines.

The Electrodeposition Division elected the following officers: Chairman, George B. Hogaboom, 557 Stanley St., New Britain, Conn.; vice-chairman, Charles S. Witherell of New York; secretary-treasurer, William Blum, Bureau of Standards. Directors: Lawrence Addicks, New York; E. F. Kern, New York; F. C. Mathers, Bloomington, Ind., and O. P. Watts, Madison, Wis. Foreign representatives: W. E. Hughes of London and Bertram Wood, Melbourne, Australia.

Entertainments and Excursions

The local committee was very lavish with its entertainments and Messrs. Boynton, Rouse, Stone, Moore, Tillman, Boyles, Meade and others spared no effort in making the visit of the electrochemists a most enjoyable one. The weather man, too, smiled his best and accordingly the boat trip, the auto tours and the golfing were enthusiastically attended.

Thursday evening at Johns Hopkins University Prof. R. W. Wood delivered a most fascinating lecture on "Fluorescence," illustrating his remarks with many original experiments. Particularly interesting were the reproductions of tests made during the war in detecting secret messages in passports, etc. The nickel glass developed by Prof. Wood which will permit ultraviolet rays to pass through but not the visible was demonstrated and its value to convoys during the war pointed out.

Friday evening the members were the guests of the Engineers' Club of Baltimore. Prof. Roscoe R. Hyde introduced his troupe of trained red-eyed flies and guinea pigs and divulged to mere electrochemists the secrets and eccentricities of the Mendelian law. Of somewhat lighter texture was the spiel by Monsieur Cheval on "Rope as a Byproduct of the Yeast Industry." The whole trick lies in training the yeast bugs to multiply by addition instead of by division. Dr. Northrup introduced his famous "sneeze," Dr. Hering, assisted by "Lid," entertained the members with a selection of historical Section Q songs, and the climax of the "show" was the award of the Pickles Medal to H. C. Parmelee, master of the *Weekly Dope Sheet*.

Friday afternoon the committee had arranged for a glorious boat trip on the steamer Latrobe. It was an exceptional opportunity for "getting together" and making new friends. The weather was ideal and everybody was in the very best of spirits. Two stops were made on the way—the first at the United States Industrial Alcohol plant, the largest of its kind in the world.

DR. CARL G. SCHLUEDERBERG
President American Electrochemical Society

The storage capacity totals 18,000,000 gal. of molasses delivered at the plant in tank steamers. The daily production of alcohol amounts to 50,000 gal. of 96 per cent. As a byproduct, 3,000 lb. of carbonic acid is shipped per day. Formerly all of this gas was wasted. The fermentation tanks have a capacity of 138,500 gal. each.

The second stop of the Latrobe was at the plant of the Davison Chemical Co. Here the center of attraction was Dr. Patrick's silica gel. A number of very instructive demonstrations were made showing the wide commercial possibilities of the gel. Among the demonstrations was the manufacture of ice by the vacuum process, the drying of air for iron furnaces and the refining of oils.

For Thursday, trips had also been arranged for to many of the neighboring industrial plants—copper, oil refractories, glass and drugs. And, of course, there was golf. The Maryland Country Club is undoubtedly one of the very finest in the country.

Ladies' Entertainment

Mrs. Richard K. Meade, as chairman, with her staff of loyal helpers, gave the visiting ladies an exceptionally enjoyable time. Perfect weather contributed to the delight of an automobile trip through the Green Spring Valley, after which the ladies inspected Dr. Emerson's model dairy farm, where refreshments were served. After a lively card party at the Baltimore Country Club, the ladies were keenly interested to get a peek at Lord and Lady Astor, who were likewise being entertained at the club. Dancing at the Engineers' Club was enjoyed Thursday night, and a bounteous spread at the Hendler ice cream plant on Friday morning. A climax was reached Friday night, when at least forty ladies attended Fred Stone's inimitable play "Tip Top."

A Discussion of the Slip Interference Theory of Hardening

Hardness Caused by Dispersed Particles Is Due to a Dislocation in the Spacing of Surrounding Atoms Rather Than to Intrinsic Hardness of Particles Themselves—Maximum Hardness Does Not Involve Minimum Ductility—Extreme Cold-Work Actually Causes a Slight Softening

By PAUL D. MERICA
Research Department, International Nickel Co.

THE mechanism of the hardening of metals and alloys by cold-working has been much debated. I believe that the earlier of the two theories held widely at present was developed by Tammann and Heyn. They consider that as a metal is deformed cold—viz., below its equicohesive temperature range—it suffers internal slip along cleavage planes within each grain, first along those most favorably inclined to the direction of the applied stress, and subsequently and progressively along those planes less and less favorably inclined to this stress. As the deformation is progressively transferred to slip planes requiring applied stress, in consequence of their greater inclination to it, the metal is thus progressively hardened and its ductility exhausted by continued cold-working. Inasmuch as the adjacent grains have in general different orientations, the slipping cannot proceed in a parallel direction across them; each grain thus interferes with movement along the slip planes of its neighbor. Since this increases the resistance to slip, it increases the measured hardness of any such aggregate of grains.

However, the adherents of the so-called amorphous metal hypothesis, Beilby, Desch, Rosenhain and others, declare that the above explanation is not sufficient. They say that the increased hardness obtained by cold-working a metal is in part also due to the generation of a layer of relatively hard and viscous amorphous cement-metal along each plane at which slip has occurred, which amorphous metal acts to rigidify this plane and prevent further slip.

Limitations of Former Theories

Neither of these theories attempts to explain the natural hardening of metals—i.e., that by alteration in the chemical composition of alloys and obtaining in the fully annealed state. That is, however, the purpose of Messrs. Jeffries and Archer's hypothesis on the hardening of metals by slip interference.[1] Following more closely the former than the latter theory, they have taken a definite forward step and affirm that interference with slip along these cleavage planes within a grain may also be caused by the presence there of a second phase of any material either in atomic or in colloidal dispersion, these particles acting in a sense as keys. The increased hardness of solid solutions is thus explained by them. Furthermore, the hardness observed in steel, particularly manganese and high-alloy steels and in duralumin, seems to be imparted to a maximum degree when the hardening particles, cementite and $CuAl_2$ respectively, are present not in atomic dispersion but in molecular groups of perhaps colloidal size. They point out that the effectiveness of a certain per cent by volume of a keying material must in general increase as its degree of dispersion and fineness increases and are obliged to assume, in order to account for the phenomena observed in duralumin and steel, that this effectiveness, however, again diminishes when the particle has become so small as to lose its crystalline character. For this they give no explanation.

This theory has the advantage of presenting a readily visualized picture of the mechanism of hardening by dispersed particles within a metallic grain. It also agrees well with our experience in the effect of fineness of structure on hardness and strength. I believe that there can be no doubt that hardness in such cases is caused by the interference to slip caused by these particles and that in general this effect must increase with increased dispersion of a given volume of the particle material.

Messrs. Jeffries and Archer are inclined to think that the hardening action of dispersed particles when present in relatively small amount—from 1 to 10 per cent by volume—cannot be due to any added factor of cohesion introduced by the presence of the particles, but that these particles act merely to develop in a better manner the latent cohesion of the original metallic grain. They believe that this cohesion is entirely sufficient in all cases to account for the increased hardening observed. With this statement I cannot fully agree, although the modification of it which I should like to suggest is, I think, not fundamentally different from the sense of Jeffries and Archer in their development of this theory. My thought is that the added resistance to slip produced by the presence within the slip plane of a key particle is not literally due to the necessity of shearing this colloidal particle during the act of slip, but that from its presence there result additional atomic forces, chemical in nature, acting between this particle and the surrounding layers of atoms of the solvent grain.

Number of Keys Required to Lock Each Plane Once

That a strictly literal interpretation of the keying action is not desirable should be evident from the following considerations: In a round grain of metal (considered henceforth only in two dimensions for the sake of a simplification, which does not affect the results of the reasoning) of diameter D we may suppose that there are two systems of potential slip planes at right angles to each other, the individual planes being separated by a distance of 10^{-7} cm. It may readily be seen in Fig. 1 that all of these planes can be keyed by a double row of circular particles situated along a diametral line at 45 deg. to the planes; with particles to be

*Presented at a meeting of the Institute of Metals Division, American Institute of Mining and Metallurgical Engineers, Feb. 20, 1922.

[1] "The Slip Interference Theory of the Hardening of Metals," by Zay Jeffries and R. S. Archer, CHEM. & MET. ENG., June 15, 1921, vol. 24, p. 1057.

contiguous with one row staggered with respect to the other by half the diameter of the particle d. Furthermore this same number, n, of particles necessary to accomplish this could be arranged in practically uniform distribution within the grain in such a manner as still to key perfectly every slip plane once. We can regard this number of key particles, therefore, as the minimum necessary to key all slip planes and at the same time be present in uniform distribution. If p is the volume per cent (or, as we are taking it, area per cent) of the key particle material we have the following relations:

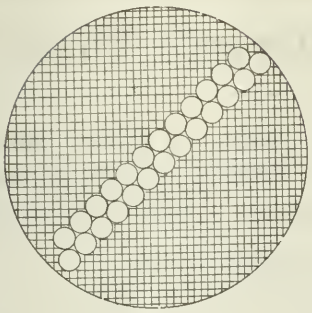


FIG. 1—DISTRIBUTION OF KEY PARTICLES TO KEY EACH SLIP PLANE ONCE

$$\tfrac{1}{2}nd = D \text{ and } \tfrac{\pi}{4}nd^2 = \tfrac{\pi}{4}D^2p$$

Let k be the number of times each slip plane is keyed. Consideration shows that k is identical with the ratio of half the length of the string of key particles to the diameter of the grain. Therefore $k = \frac{nd}{2D} = \frac{Dp}{2d}$

Now the force necessary to shear through all key particles on each slip plane, taking s equal to the unit shearing stress of the key material, is equal to $sdk = \frac{1}{2}sDp$, and is hence independent of the number of key particles on each plane and hence within the grain. This is not a reasonable conclusion if we require that the resistance to slip increase with the degree of dispersion, since it is not indicated.

Further, the order of magnitude of the particle necessary to properly key all slip planes is not convincing. Take the example of duralumin: In a grain 0.1 mm. diameter containing 5 per cent by volume of $CuAl_2$, all slip planes on any cross-section would be perfectly keyed as soon as the number of particles had increased to 800 with average diameter of 0.0025 mm., and on the above assumption further increase in dispersion would not involve any further increase in slip resistance. On this basis the particle size causing maximum hardness would also depend on the size of the aluminum grain, which does not seem reasonable.

Atomic Forces Also Required

I have preferred to ascribe the slip interference to atomic forces acting at the surface of the key particle and through one or more atomic layers of the surrounding matrix. Thus one can regard the particle as in a sense adsorbing the surrounding medium or solvent and surrounding itself with a film whose properties are markedly different than in the undisturbed atomic matrix of metal. In fact we must assume that within this film the cohesion is greater than without it and that it is to this added cohesion that the interference and consequent additional hardness is due. When you thus admit the strengthening of surrounding metal by means of surface film action, it is readily seen that with a small enough particle the whole mass of the grain could be so strengthened.

Thus, if m be the thickness of the film of metallic solvent adsorbed by the hardening particle, the volume of the grain so affected or adsorbed and strengthened is equal to

$$V = \frac{n\pi}{6}(d + 2m)^3$$

and

$$n = \frac{D^3}{d^3}p$$

From these expressions the ratio of this volume V to that of the grain is

$$k = p\left(1 + \frac{2m}{d}\right)$$

When the whole volume of the grain has been so adsorbed by the key particles and strengthened by their presence, $k = 1$ and

$$\frac{1}{p} = \left(1 + \frac{2m}{d}\right)^3$$

This requires that the particles of $CuAl_2$ to give maximum hardness in duralumin, following this condition, have an average diameter of about 10^{-6} cm., or 100 molecules, if we assume that the surface film of aluminum atoms adsorbed by each particle is 10^{-8} cm. in thickness. This seems a reasonable value and agrees well with that estimated by the authors.

I believe that this conception is not outside of or contrary to the sense of Jeffries and Archer's theory, although in one particular it differs from it in that it requires an actual strengthening effect exerted by each particle—either atom, or molecule, or group of molecules—on the atom layers of solvent immediately surrounding it and outside of its own limited volume. That we must grant that there is added cohesion in the case of at least some solid solutions I think we shall be obliged to admit after a consideration of the work which Mr. Bain[2] has been doing on the atomic structure of such solutions. Thus he finds that a copper lattice takes up zinc atoms to form high brass without alteration of the lattice, the zinc atoms merely substituting identically for the copper atoms. Now, since the lattice is not altered, we can scarcely in this case speak of a key action in a literal sense; nevertheless the hardness of the solid solution is greatly increased. In my opinion we are obliged to assume a different summation of atomic cohesions when the zinc atoms are in place than when they are not.

Adsorbed Atoms Involve Formation of Molecules

I am inclined to think that one cannot speak of an atom adsorbing surrounding atoms in the form of a film except in the sense that a new molecule is formed. Therefore the picture I have drawn above of the strengthening effect of small particles as due to the films of solvent metal formed around them must be considered as limited to molecules or groups of molecules. When the molecule is actually disintegrated into atoms and goes into atomic dispersion in true solid solution, this precise effect disappears and the resulting properties are due rather to the cohesion conferred simply by the atomic arrangement of the new atoms. It is conceivable that this cohesion may be much less than that due to molecule-groups with adsorbed solvent.

Thus it would seem that this slightly modified conception of the hardening theory is more elastic in that it more readily permits of an explanation of the less pronounced hardening effect of atoms of copper on aluminum than of molecule-groups of $CuAl_2$, and indicates that the reason for the apparent anomaly is in the

[2] "Crystal Structure of Solid Solutions," by Edgar C. Bain, read before the February, 1922, meeting of the American Institute of Mining and Metallurgical Engineers. Abstracted in CHEM. & MET. ENG., vol. 26, No. 14, p. 655, April 5, 1922.

nature of the field of force surrounding copper atoms and that surrounding the molecule or molecule-group of the compound. I may say that I am rather inclined to agree with Jeffries and Archer in their contention that in true solid solutions, both duralumin and austenitic steel, the copper and the carbon respectively are present in atomic dispersion.

Maximum Hardness Does Not Necessarily Involve Minimum Ductility

Another conclusion is drawn by Jeffries and Archer which does not seem to be quite in accordance with the facts, nor does it seem to be a necessary consequence of their theory. That is that maximum hardness is accompanied by minimum ductility. Now this is indisputably true in general, but I believe that there are exceptions to the rule. Of course we may dispute about the method of properly measuring ductility, and I for one must confess myself at a loss as to how that interesting property may be precisely measured. But accepting the current methods of its measurement, it is a fact that the hardening of duralumin during aging after quenching is often accompanied by an increase of ductility (as measured in the tensile test), particularly when the aging is carried out at lower temperatures. Furthermore, I recall some data presented some years ago by W. R. Webster[3] showing that the tensile test ductility of common high brass, a solid solution of zinc in copper, is greater than that of copper and of course it is also harder and stronger. In fact, it was striking to note that an addition of zinc to copper raised simultaneously the tensile strength and the ductility. Information from some of the brass manufacturers would be interesting as to whether high brass is actually more malleable and ductile in manufacture than copper. Looking at the matter from the standpoint of the slip interference theory, if the hardening is due merely to increased atomic force or bond on each potential slip plane, the slip planes remaining identically the same, there seems to be no reason for assuming anything in particular about how the ductility is affected by key particles. If anything is to be deduced, the conclusion would be that ductility is unchanged rather than that it is diminished.

I have for some time believed that our knowledge of hardness, both in practical and in theoretical respects, would be greatly improved if instead of measuring merely the hardness at one value of the plastic deformation, such as we do in the current methods, we should measure also the rate at which this hardness increases with deformation; we should determine in fact the "deformation rate of increase of hardness." For example, a comparison of this rate for aluminum and for quenched and for tempered duralumin would indicate whether the effect of the dispersed particles of copper or of $CuAl_2$ was merely to increase the force necessary to produce slip on each plane or whether they actually altered the mode of deformation. If the former, the ratio of the rate of hardening of any one of the materials to that of the other should be the same as that of any particular value of the hardness taken under corresponding conditions, whereas if the actual mode of deformation is altered by the presence of the copper there might not be such correspondence.

Softening by Extreme Cold-Work

The course of the hardness-deformation curve is known for many metals and alloys in the initially annealed state and it seems to be of the same general form for all which have been studied. And this is true whether we consider the stress-strain curve in a tensile test or the hardness of sheet after cold-rolling to greater and greater reductions. The unit force or stress required per unit of deformation (plastic or permanent deformation only is of course here considered) increases with progressive deformation, but at a progressively decreasing rate; finally—at least for copper and copper-nickel alloys—the rate passes zero and actually decreases. The cold-worked metal becomes softer. The latter phenomenon occurs in Monel metal, for example, after about 95 per cent reduction by cold-rolling.

Now this is certainly not what we might expect from a literal application of the theory of Tammann and Heyn. For in general the tensile stress required to produce slip on planes making an angle, θ, with the normal to the axis of the tensile stress is equal to $s \div \sin\theta \cos\theta$ when s is the shearing stress required to produce slip.

Now this stress is least when slip is occurring on the 45 deg. planes and is equal to $2s$, and it increases as the planes are affected, making a greater or a lesser angle, but its rate of increase is continually increasing, not decreasing, and it finally becomes infinite when the angle is either 0 or 90 deg. This conclusion does not fit the facts.

It is of course obvious that although an application of tensile stress equal to twice the shearing stress required to produce slip on each unit slip plane should produce slip on the 45 deg. planes of an aggregate of metallic grains, it cannot in general do so owing to the interference of grains whose slip planes do not lie in this particular direction. The stress required to start slip depends therefore on the arrangement of all of the grains composing the specimen and represents a statistical summation or average of the individual stresses required for each grain with its different orientation. Its application not only produces slip along some favorably inclined planes but along some which are less and even least favorably inclined and it serves probably also to rotate some grains bodily which could not otherwise take part in the deformation.[4]

We may consider then that each increment of applied load has to overcome the resistance of a certain combination of internal stresses, defined by the orientation and the size of the component grains, the total resistance amounting to the summation or integration over all of the infinitely small increments of resistance. What is the nature of these combinations? Whatever it may be, I think we may feel confident that there are combinations of varying probability of existence; thus one with all slip planes of all grains inclined at 45 deg. to the direction of the applied tensile stress is highly improbable, whereas one with all possible orientations and shapes of grain is the most probable. Now, although I am not in position to give this statement a rigid proof, it seems reasonable to assume since there is no type of unit grain resistance that is infinite (i.e., if a grain is so oriented that no internal slip is possible, the whole grain may be rotated by external pressure into a position in which this is possible), that the most probable combination of grains is

[3] *Proc.*, Int. Soc. Testing Materials, 1912, vol. 7, p. 6.

[4] See "Mixed Orientation Developed in Crystals of Ductile Metals by Plastic Deformation," by Edgar C. Bain and Zay Jeffries, Chem. & Met. Eng., vol. 25, p. 775, Oct. 26, 1921.

characterized by the maximum integrated resistance to deformation. At least we can readily see that some, even many, other combinations, less probable, will have what may be seen as a minimum resistance.

If this be assumed to be true, we may derive the well-known form of the stress-deformation curve, since the number of combinations present of any arrangement is of course proportional to the probability of the arrangement. Therefore there are relatively few arangements present giving a low initial stress necessary to start slip, but as we increase the load to that characteristic of the most probable arrangement (assumed to require the maximum load to produce deformation) the number of arrangements or combinations present increases and in consequence the increment of deformation also increases, since each combination contributes a certain amount to the total deformation. The form of the stress-deformation curve should therefore be the same as that of one side of the probability integral, which indeed it is.

Now this is, of course, but a first approximation to the truth and is only perhaps valuable as a picture illustrating the statistical nature of deformation in metal grain aggregates. It neglects, for example, the plain fact that the very act of deformation alters the existing combinations for the next stage. But the explanation must lie in the latter fact that finally the metal becomes softer, the resistance of the combinations less to continued deformation. We must assume, I think, that finally the most formidable obstacles to ready slip are permanently removed by rotation, and the great amount of deformation already suffered has served to impart direction to the grains themselves, consequently increasing the number of less probable, less resistant combinations.

An interesting fact should be noted as a theoretical consequence of a statistical theory of deformation—namely, that the smaller the grain size (or more properly the smaller the ratio of grain size to size of test specimen) the greater should be the consistency of agreement between tests of the same material but different specimens. With test specimens involving few grains there should be quite marked variation noticeable, particularly in the yield point.

I believe that if we could by a sufficient study of the mechanical properties of single grains lay down the fundamental principles of grain slip and define the forces requisite to produce it, it would become possible to apply these principles by means of the statistical methods used successfully for gases to the consideration of the mechanical behavior of grain aggregates, and I have no doubt that this will one day be done. In that day metallography can properly lay claim to be as accurate a science as mechanics itself!

Cadmium Electroplating

The udylite process of cadmium electroplating covered by United States patents 1,383,174, 1,383,175 and 1,383,176, with other patents pending, embodies electroplating with the metal and subsequent heating in an oven for several hours at 150 to 200 deg. C., by which the cadmium coating is alloyed with the metal of the article coated. Late in 1921 this process was installed in eighteen plants and contracts were made for installations in nine more plants. This process has been applied to rustproofing locks, hardware, kitchen-cabinet and refrigerator trimmings and automobile parts.

New Customs Service Sugar Laboratory

The Bureau of Standards has been of assistance to the Customs Service of the Treasury Department in connection with the installation of the new laboratories for sugar analysis at Baltimore. This work, which is now practically completed, has included the installation of a chemical laboratory equipped with model benches with alberene tops, hoods and the necessary accessory equipment. A polarimetric laboratory has likewise been designed for the analysis of imported sugars.

Owing to the fact that the building which had to be utilized for this sugar laboratory was not equipped with all the appliances needed, it has been necessary to plan for the installation of a steam boiler, hot water heater, vacuum and compressed air outfit, as well as the necessary gas and electrical connections essential for work of this kind. By detailing a member of the staff of the bureau to Baltimore and through the loan of apparatus, it has been possible to carry out sugar testing at Baltimore even before the completion of the new laboratory. So far tests on the exchange samples of sugar for comparative purposes show satisfactory agreement between this and other laboratories of the Customs Service.

Tests of Various Types of Extinguishers for Zinc Dust Fires

Tests have recently been made by the Bureau of Mines on the effectiveness of water, sodium carbonate solution, carbon tetrachloride, silicon tetrachloride and a frothy mixture as extinguishers for zinc-dust fires. The frothy mixture extinguished the fire most quietly and effectively, so it was tested on a larger fire in 300 lb. of zinc dust. Three $2\frac{1}{2}$-gal. foam extinguishers smothered the fire, but danger of rekindling had passed only after lapse of several hours, due to retention of heat in the metal by the non-conducting foam blanket.

Thermal data show that water, carbon tetrachloride and carbon dioxide react with zinc with liberation of considerable heat, carbon tetrachloride producing most. However, no violent reaction occurred when red hot molten zinc was poured into carbon tetrachloride.

Although some fire extinguishing materials may be injurious or may be decomposed in fires to produce toxic gases or vapors, no especially poisonous gases or fumes are evolved from burning zinc itself or from the action of extinguisher material on the zinc.

To Investigate Paper Pulp Sources of Australia

According to a report which appeared recently in the *Industrial Australian and Mining Standard,* the West Australian Forests Products Laboratory and the Commonwealth Institute of Science and Industry have been authorized to carry on experiments on a semi-commercial scale, with a view to ascertaining whether it is possible to produce paper pulp from Australian timber. The federal government is to spend £2,490 a year in salaries and provide equipment for carrying on the investigations. In addition, the institute will spend a special appropriation in carrying out experiments. The Western Australian Government contributed £1,900 and certain newspapers £600, while other states have contributed £1,300. There was a private contribution of £100 from a Victorian paper manufacturing company. The Western Australian Government has offered £5,000 conditionally upon the Commonwealth Government finding a similar amount for the purpose of building a laboratory in Western Australia.

Handling the Finished Products of Industry—II

Preparing Yeast for the Market at the Plant of the Fleischmann Co. in New York City—Automatic Equipment Used for This Work—Principles of Handling Illustrated by This Installation*

By GRAHAM L. MONTGOMERY

THE FLEISCHMANN CO. has in New York City a plant in which yeast is compressed and wrapped in the various packages that are offered for sale. As yeast is used in baking and enters in other ways into food, it is necessary that the yeast and the plant in which it is handled be maintained in as absolute a state of cleanliness as it is possible to reach. In order to achieve this end in the best way it is necessary to use automatic machinery. The machinery originally installed was for mixing the yeast with water, compressing and forming it, cutting it into cakes of the desired sizes and wrapping and labeling these cakes. Conveyors have recently been installed to handle the yeast used in making the 1-lb. cakes which are supplied to bakers. This has worked a noteworthy improvement in this department.

The yeast is received from the manufacturing plant in Peekskill, N. Y., in a dry state, packed in paper cartons 14 x 15 x 11 in. and weighing 50 lb. each. Shipment is made by rail, motor truck and barge, the greater part coming by barge and being transferred at the pier from the barge to motor trucks which transport it the short distance to the plant.

Handling Bulk Yeast at the Plant

The yeast cartons are unloaded by hand from the motor trucks and then placed on a straight steel slide which leads from a hatchway in the sidewalk outside the building to a gravity roller conveyor in a basement storeroom as shown in the accompanying illustration. This conveyor runs across the upper part of this storeroom. It is hinged at one place so that an 8-ft. section may be raised to permit a clear trucking aisle. This gravity roller conveyor is of standard design, having ball-bearing steel tube rollers 1.9 in. in diameter, 16 in. long and spaced 4 in. on centers. The bed, rails and supports are of angle iron.

The cartons of yeast pass on this conveyor across the storeroom into the cold room. The conveyor enters and leaves the cold room through insulated refrigerator doors, which are kept closed when the conveyor is not in use, making it easier to maintain the required temperature of 22 to 24 deg. F. in this room. When yeast arrives at the plant faster than it can be used, it is unloaded by hand in this cold room and stored to await the time when it is needed in the packing room.

From the cold room the cartons pass out into the main basement of the packing building. The gravity conveyor leads by one 90-deg. bend directly to the intake of the vertical package elevator shown on the accompanying illustration. This elevator takes the cartons automatically from the gravity conveyor, one at a time, and raises them to the first floor, depositing them on another gravity roller conveyor. The construction of a vertical package elevator makes it necessary for the packages to be carried over the top of the elevator and lowered on the other side somewhat below the lowest part of the two head sprockets before a discharge can be made. This is due to the automatic discharging arrangement, which is made up of steel fingers. These fingers, stationary in location at the point at which it is desired to make the discharge, come opposite the spaces between the bars which make up the pivoted tray on which the carton or package is carried. As the tray is lowered it will be seen that the fingers of the discharger remove the package. It then slides down a short incline to be taken up by whatever means is there provided.

There is an advantage inherent in the fact that the elevator must deliver on the opposite side from that on which it receives its load in that it occasions no reversal of the direction of progress of the package through the conveying system and the resulting installation is cheaper and requires less space. In this particular case it is necessary to start the yeast in the packing process at a point near the ceiling of the room. For this reason it has been necessary to include in the system this additional elevating unit.

The short length of gravity roller conveyor at the outlet of the package elevator conveys the cartons to an inclined slat conveyor which elevates them to a sufficient height for the operations which the yeast is to undergo in the packing process. This will be seen by reference to the illustration. This inclined slat conveyor is 14 in. wide and 14 ft. on centers and is made up of roller chain and steel slats, the chain traveling in the guides provided in the frame for that purpose. The drive of this conveyor is by means of an electric motor mounted on the frame. This conveyor and the gravity conveyors at either end of it are suspended from the ceiling.

The cartons are discharged from this slat conveyor onto a gravity roller conveyor 12 ft. in length which conveys them around a 90-deg. bend and deposits them on the breaking table. Both the gravity conveyors on the first floor are the same in specification as that in the basement. When the carton reaches this point the yeast has completed the movements coming under class 1 handling as defined in the first paper of this series. Here it enters the forming and wrapping processes which come under class 3, as defined in that paper.

Preparation of the Yeast for the Wrapping Machines

At the breaking table the yeast meets with the first manual handling since it was unloaded from the truck in the street, except in cases where it has been held

*Part I of this series was published in Chem. & Met. Eng., vol. 26, No. 18, p. 823, May 3, 1922.

for storage in the cold room, in which case it had to be taken off the conveyor and put back on it by hand. Here it is dumped from the cartons against a steel plow situated in the middle of the entrance to a steel slide. As it strikes this plow it is broken up into smaller pieces. The steel slide takes these pieces down a short distance into the mixer. This mixer is a standard type of Werner & Pfleiderer dumping mixer of sufficient capacity to mix 200 lb. of yeast per minute. The yeast has reached this mixer in a dry and crumbly state. Here a certain amount of water is added and thoroughly mixed through the mass until it reaches the proper consistency for compressing.

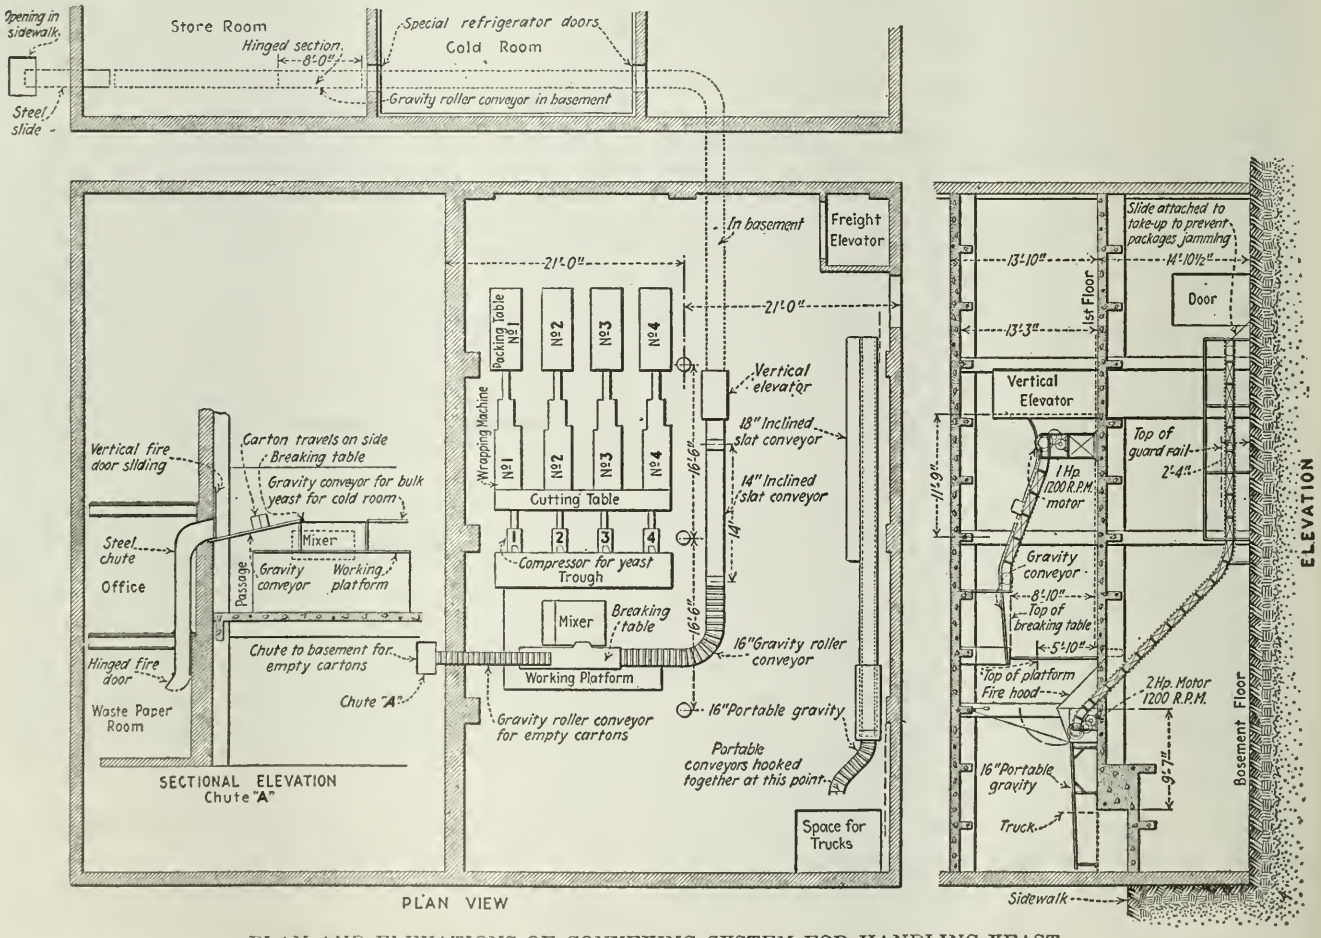
As soon as this mixing is completed, the yeast is dumped into the long trough marked on the accompanying drawing. There is not sufficient water in the yeast to cause it to flow readily and a worker stands here with a shovel and distributes the yeast in the trough to the four spouts which feed the four compressing machines. The yeast passes through these four spouts into hoppers which form part of the compressing machines. Under each hopper is a small screw conveyor which picks up the yeast and forces it into the compressing machine. From this it is extruded through a die in the form of an endless square bar with the exact cross-section required in the finished 1-lb. cake.

As the endless bar of yeast is extruded it passes onto a small flat belt conveyor, the forward motion of which is exactly timed with the rate of extrusion. This belt conveys the bar under the cut-off—at present operated by hand, but which without doubt will before long be mechanically operated. This cut-off is a tightly stretched wire mounted in a swinging frame with its plane of motion at right angles to the motion of the bar of yeast. When a measured length of yeast sufficient to weigh 1 lb. has passed under the cut-off it is operated and in this way uniform pieces of an exact pound in weight are obtained. The operator piles these on the table which is shown in the drawing as situated at the inlet end of the wrapping machine. Random samples are weighed on a scale mounted here in order to keep a running check on the operation.

Wrapping 1-Lb. Cakes of Yeast

The operator situated at the head end of the wrapping machine takes the cakes of yeast—both those from the pile on the table and those from the scale—and places them on the flat, feeding belt conveyor which forms the first part of the wrapping machine. They are put on this belt with their long dimension perpendicular to the axis of motion of the belt. This belt carries the cakes into the machine where each is wrapped and sealed in a transparent sheet of paraffined paper on which an appropriate label is printed. The wrapped cakes are then discharged from the machine onto a second flat belt, which conveys them to the packing tables. Here they are packed by hand in cartons for shipment. These cartons are placed, when filled and sealed with paper tape, on hand trucks and wheeled to the desired point for storage or shipment.

The wrapping machines, designed and patented by the Fleischmann Co., are extremely ingenious. They are simple in operation and have by far less parts than most machines which are built for this class of



PLAN AND ELEVATIONS OF CONVEYING SYSTEM FOR HANDLING YEAST

work. The capacity of each machine is fifty wrapped and sealed 1-lb. cakes per minute. The four machines installed in this plant thus have a total capacity in 1-lb. cakes of 48 tons for each 8-hour day.

Getting Rid of the Empty Bulk Yeast Cartons

The cartons from which the bulk yeast has been removed are placed by the workman at the breaking table on the empty carton conveyor. This is a gravity roller conveyor of the "sensitive" type. It is made up of 1⅛-in. diameter rollers spaced 2 in. on centers and 18 in. long. The rollers are carried by means of ball bearings on through shafts, these shafts being fastened in the angle iron frame of the conveyor.

The cartons are carried by this conveyor to the adjacent wall, where they pass into the 18 x 18-in. straight steel chute shown in section-elevation "A" on the accompanying drawing. This chute, provided with safety fire doors, held open by fusible links at its intake and outlet, takes the empties to the basement and discharges them on a receiving table. Here a workman collapses them and ties them in bundles for shipment back to the plant in Peekskill.

How the Product Is Handled in Shipping

As shown above, the wrapped cakes are packed in cartons directly adjacent to the wrapping machines and thus no handling is necessary there. All of these cartons which are for immediate shipment are wheeled directly to the shipping platform on the trucks on which they are placed when packed. This is possible because all these operations occur on the first floor of the building. Those which are to be placed in storage for future distribution are taken to the basement by freight elevator and placed in storage in the room in which the foot of the vertical package elevator is situated.

To take these packages from storage to the shipping platform an inclined slat conveyor 18 in. wide and 43 ft. on centers is provided. This conveyor starts with a horizontal run of about 20 ft. along the wall of the room in which the cartons are stored. This permits the loading of the conveyor through the entire length of this run. At the end of this straight run the slat conveyor raises the packages up through a hatch in the floor to a point somewhat above the level of the shipping platform. Here they are loaded into motor trucks for distribution by means of a length of portable gravity conveyor fed directly from the discharge of the slat conveyor. This handling in connection with the shipping is of the second class described in the first paper of this series.

Equipment Used in This Installation

The gravity roller conveyors used in this installation are all of standard design and size. The inclined slat conveyors are standard design, but these must always be built for the particular distance on centers and rise which the job requires. The vertical package elevator is a standard machine. The chutes, as with all chutes, are built to fit the job. All this equipment is painted with either aluminum paint or white enamel. This serves the purposes of cleanliness and also conforms well with the surroundings, for the rooms are finished in white enamel and white glazed tiles.

All the conveyors described above were furnished by the Dow Co., Louisville, Ky., except the vertical package elevator, which was furnished by the Robins Conveying Belt Co., New York City.

The decisive reason which makes the use of mechanical handling equipment and automatic machinery advisable in the installation just described is the fact that the product—a food product—must be kept scrupulously clean. While it may be possible with hand methods, it requires extreme care and much oversight to accomplish this end. The use of this equipment provides a much cheaper, quicker and less burdensome way of obtaining the desired result.

The combination of conveying equipment and automatic machinery here described has incidentally effected several other advantageous results for the plant. First, it has eliminated all possibility of confusion in the transportation of the yeast by preventing any crossings in the flow of material through the plant. Second, it has eliminated a number of workers who would otherwise have been employed and has thus made the work more economical. Third, it has lessened the burden of management in the plant because it is nearly automatic in operation. Fourth, by producing more completed packages in the same space, it has lessened the overhead of the operations. And fifth, because the cleanliness necessary has made a showplace of the plant, it has a distinct advertising value.

The writer wishes to acknowledge his indebtedness to L. L. Tieman, constructing engineer of the Fleischmann Co., and to H. Dunning of the Dow Co. for courtesies tion and drawings furnished.

Desulphurization of Cast Iron

It is commonly known that there are three practicable methods of reducing the amount or the effect of sulphur left in the pig iron coming from a blast furnace. In the first place, if sufficient manganese is present to form MnS with all the sulphur, this inclusion is not nearly so damaging as FeS existing in low-manganese pig. This expedient is the only one commonly used in the foundry. Secondly, if pig iron be kept molten in a mixer or other large container, MnS will float to the top and the sulphur burn off. Thus there is often a loss of one-third the sulphur between blast furnaces and steel furnaces from this cause, especially in high-manganese pig. Third, advanced foundrymen who have installed basic electric furnaces can produce irons containing as little sulphur as desired by correct refining under a carbide slag.

In the past there have been many rumors of substances which could be added to cupola metal in the ladle and sulphur forthwith vanishes. Many have been tried and found wanting. Speaking informally before one of the recent sessions of the American Electrochemical Society at Baltimore, Dr. Richard Moldenke said that a new physic of this sort (probably a potash compound) had attained a wide vogue in Germany, and he was anxiously awaiting receipt of a quantity of the material so it could be tested on American irons.

The method was said to be: After the hot cupola metal had been tapped into a ladle all the slag was carefully removed, and a small amount of the compound added. This readily alloyed with the iron, causing more or less violent circulation in the metal. In 4 or 5 minutes the currents had quieted down and a very thin slag appeared, which was absorbed by a little lime, and carefully skimmed. Analysis would then show that the metal, originally, say, 0.14 S, retained but 0.07 per cent. It it reported that half of this remainder could be removed by a second application.

Metallic Sodium—I

A Critical Review of the Development of the Metallic Sodium Industry—Wide Variety of Processes Based Upon the Electrolysis of a Molten Bath Consisting of or Containing a Sodium Compound Such as Caustic Soda or Salt

By HOWARD E. BATSFORD

In THE attempt to prevent a duplication of effort in the further development of metallic sodium work, and to provide an easy way for the beginner to get an insight into the practices of those men who labored very diligently in the field of alkali metal production, the author has made a summary of all the available data on this subject, condensing it in such a manner that there is very little repetition, except for comparison.

An attempt has been made to explain or comment on the important parts of each patent, with a view to showing why the particular patent is not now in commercial operation. The greatest fault of the inventor seems to be in trying to make the apparatus complicated, which instantly means greater cost, difficulty in construction, and finally costly operation and replacement of parts. In many cases the patent is not made in accordance with the actual apparatus in question, since the inventor felt compelled to disguise his real secrets so that they are unrecognizable.

Naturally, the largest share of the earlier work was carried out by chemical means, but in the early '90s electricity became more available and men turned to it as to a panacea for all ills. One of the greatest drawbacks to sodium reduction from its salts was the extreme temperature required; the electrolytic cell seemed to solve the temperature problem but introduced other difficulties such as metallic fog, contamination of other materials by selective depositions, and destruction of cell and electrode material. These evils have slowly been eliminated until today there are on the market, or rather available for commercial use, cells for making metallic sodium of high purity from either fused caustic soda or fused salt, at prices which make it profitable to manufacture, provided the market for the finished product is large enough.

Electrolytic Production of Metallic Sodium

There had been several attempts to make sodium electrolytically after Davy produced small quantities of it with his voltaic cell, but Matthiessen, following the lead of Bunsen, in 1855 succeeded in making it by electrolyzing a mixture of salt and calcium chloride in the proportions of 2 NaCl to 1 $CaCl_2$. This mixture had been dehydrated by heating with ammonium chloride and freed from basic salts.

The troubles encountered by the latter were noticed by Hopfner, who sought to avoid them by using soluble anodes such as copper or silver. These were expected to retard the losses due to solution of chlorine in the melt and the resultant reaction with the sodium, but proved of no avail, since the chlorine gradually passed through the electrolyte and attacked the sodium.

In 1890 Grabau made a cell in which he used bell-shaped compartments for collecting the sodium and chlorine. These were quickly destroyed and were replaced by the formation of solid electrolyte on the walls. His explanation was that the corrosion was due to leakage of current more than to the corrosive action of the electrolyte. The frozen layer was kept in condition by cooling the annular metal walls of the cell.

Grabau made further use of a mixed electrolyte for reducing the melting point of the bath, as Matthiessen and Bunsen had done before him. The bath used was 3(NaCl, KCl) + $SrCl_2$.

The sodium produced contained about 3 per cent of potassium but no strontium. Barium chloride does not melt so easily, and calcium chloride is so difficult to free from water that he preferred strontium chloride to the two others. The chief causes of failure seem to be the high voltage, frequent clogging of cells and necessity of careful attention.

Grabau figured that at the high temperature necessary for the operation great loss of metal occurred owing to formation of sub-chloride of sodium. This sub-chloride was partly oxidized at the surface of the bath and partly diffused to the anode, where it combined with the chlorine.

The Castner Process

In 1892 Hamilton Y. Castner made very important additions to the sodium industry by discovering a process by which metallic sodium could be made commercially from fused caustic soda. Fig. 1 shows the cell as described in U. S. Pat. 452,030; May 12, 1891.

This process consists in electrolyzing caustic soda constantly maintained at not more than 20 deg. above its melting point; also in using a gauze or screen between the electrodes and a superimposed dome for collecting the metal. The temperature must be kept low to prevent re-solution of sodium metal by the bath, and recombination, which takes place actively at higher temperatures.

Caustic soda melts at 308 deg. C. if pure, but down to 300 deg. C. if containing slight impurities.

It is electrolyzed preferably within 10 deg. of its melting point but never above 325 deg. C.

Within 5 deg. of its melting point almost the theoretical quantity of sodium is obtained, at 10 deg. above about 90 per cent, and this is the best obtainable in commercial practice. Above this the yield decreases very rapidly and at 20 deg. above its melting point recombination is as active as decomposition and the bath yields no metal, but lies "dead."

On commencing to pass the current through melted caustic soda, any water present is at first decomposed, evolving hydrogen and oxygen only until every trace of water is gone. After that sodium and hydrogen

Note: Complete references to all the work discussed will be found in the chronologically arranged bibliography at the end of the second part of this article.

together appear at the cathode and oxygen at the anode. These must be kept rigorously separated or re-oxidation of the sodium will occur, and the hydrogen will be oxidized, with an explosion.

Borchers made a study of the production of sodium and arrived at the following conclusions in 1894:

For best electrolysis:

1. Alkali metal must be deposited at a metallic (iron) cathode.
2. Cathode space must permit of collection and removal of metal without the latter coming in contact with reducible substances.
3. The anode must be of carbon.
4. The anode space must permit of the easy removal of the halogen, and its walls must be constructed of material capable of withstanding the action of halogens and haloid salts.
5. No metallic particles should be present in the melt between the poles.
6. All the parts of the apparatus must be constructed of fire-resisting material.

In 1902 Janeczeke made a special study of the decomposition voltages occurring in the electrolysis of fused caustic soda.

At temperatures corresponding to the melting point of caustic soda, as we have seen before, the sodium is absorbed during electrolysis, as is also oxygen; at slightly higher temperatures these products are absorbed so rapidly that there is no decomposition.

Hydrogen may be formed primarily by deposition at the cathode or secondarily by action through the sodium and water formed at the anode.

Janeczeke says that the following reaction takes place:

$$NaOH + Na = Na_2O + H$$

Therefore, there are present H-ions in small number in the fused anhydrous caustic soda.

The decomposition voltage was found to be about 1.3 v. for caustic soda; below 1.0 v. at the cathode a quite lively generation of hydrogen takes place, the oxygen generation taking place promptly at 1.3 v.

The second decomposition point in the voltage curve is at 2.1 v. At 2.4 v. stream lines seemed to go out from the cathode into the melt with flashes of gas. These were apparently sodium particles which reacted with the caustic soda. From this and other data it was assumed that 2.2 v. represents the point at which metallic sodium is formed.

Reactions During Electrolysis of Fused Alkalis

LeBlanc and Brode published in the same year (1902) the results of their observations in *Zeitschrift für Elektrochemie* on the electrolysis of fused NaOH and KOH, as follows:

At the anode oxygen and water are formed, this water reacting with the sodium freed at the cathode with the evolution of hydrogen.

Since one equivalent of water exists for two equivalents of sodium, a current yield of 50 per cent is the maximum obtainable in such a process as that patented by Castner. In fact, the yield generally runs around 40 per cent.

At high temperatures sodium dissolves in the melt, causing evidently strongly depolarizing properties in the melt at the anode. The depolarizing effect of the dissolved sodium was so great that only at high current densities could oxygen be formed. Under these conditions the gas formed at the anode was a mixture of equal parts of hydrogen and oxygen, or detonating gas mixed with hydrogen. This throws some light on happenings in the industry.

Sometimes the cell works badly, makes little sodium and almost every minute has an explosion. It is then too hot, the melt is dissolving too much sodium, it depolarizes partly the anode, it partly reacts with the moisture present, and forms rich mixtures of detonating gas which explode.

At a lower temperature, on account of the diminished solubility of the sodium in the melt, the depolarizing effect at the anode and the formation of detonating gas is reduced to a minimum. The Castner apparatus takes the hydrogen and leads it upward inside a wire gauze along with the metallic sodium, neither being permitted to pass across to the anode.

We have here the apparent paradox, that at low temperatures hydrogen is formed at the cathode and at high temperatures it occurs at the anode. Whether the gas evolution is visible or not at the higher temperature depends on the current density.

The anodic gas generation is not, as Castner believed, a result of the increased solubility of oxygen in the melt, but it is a result of the depolarizing action of the dissolved sodium. If the former were true, we would

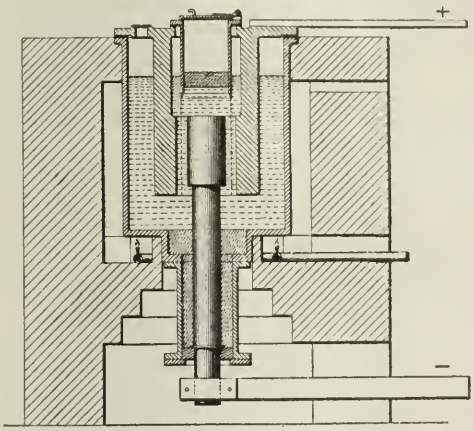


FIG. 1—CASTNER CELL

have anodic hydrogen, but with the latter we have free oxygen and the formation of water.

If sodium peroxide is dissolved in the melt, it has the same depolarizing action as the metallic sodium, but at the cathode.

In pure caustic soda melt there is nothing which exerts a depolarizing action at the anode or cathode, and on this account only small currents pass through the electrolyte at low terminal voltages.

There exist at the anode peroxide and at the cathode dissolved sodium, both of which act as depolarizer for the other electrode, and on continued electrolysis, the following reaction takes place:

$$Na_2O_2 + 2Na = 2Na_2O$$

With water at the anode the following reaction:

$$Na_2O + H_2O = 2NaOH$$

A part of the sodium also acts directly on the water. According to which reaction predominates, we have a melt saturated with sodium or sodium peroxide. Luckily we are able to get anodic or cathodic polarization at will, if we allow fresh electrolyte to flow either from anode to cathode or vice versa.

In order to get good yields of sodium, the following precautions are in order:

1. Do not let the water formed at the anode reach the cathode.
2. Get a good diaphragm.

Pure anhydrous caustic contains no H-ions or O-ions but only Na- and OH-ions, and is very hygroscopic.

In a later article by the same authors, nickel was selected as material for anode, since it does not behave as soluble anode. At least, the amount of dissolved nickel in the melt is insignificant in comparison with that which should be dissolved in accordance with Faraday's law. It is very small and easily within experimental error.

In the same year Thomas Ewan electrolyzed fused NaOH in a cell with a diaphragm of sodium aluminate or alumina or a mixture of both. A current of air (or a suitable gas) was passed over or through the electrolyte to remove water.

Acker Process

At the same time Acker patented his process for making caustic soda from fused salt, with the evident desire of finally producing metallic sodium. For this work he used graphite anodes, dipping into a bath of fused salt, which in turn covered the molten lead cathode. The lead, which was circulated through a subterranean chamber in the iron jacket of the furnace, absorbed the sodium with the formation of lead-sodium alloy. This alloy, entering another chamber in its circulation, was treated with live steam and caused to yield up its charge of sodium, with the formation of strong and pure caustic soda. The lead then returned to the cell for further sodium.

The chlorine gas left the furnace through a pipe at the top under a slight suction and was passed into lime liquor for the formation of chlorine products. It contained about 10 per cent chlorine and 90 per cent air.

The current used was 6,000 amp., the voltage 7 v. and the current density 2.9 amp. per sq.cm.

In 1903 Becker designed a cell for making sodium from a mixture of caustic soda and carbonate of soda. He kept the center of the cell molten and the walls frozen, thus keeping the walls perfectly insulated.

In 1904 C. F. Carrier reported some tests made with proportions of Na_2CO_3 up to 66 per cent. There was no improvement over the Castner process, and no evolution of CO_2 was detected between 330 and 630 deg. C.

Use of Alternating Current

Hambuechen made a study of the electrolysis of NaOH by alternating current with the following results:

The property of aluminum electrodes, which permit the electricity to pass in one direction only, is made use of for electrolyzing the caustic soda.

NaOH is fused in an aluminum vessel, in which is placed an aluminum electrode surrounded by an iron electrode; a perforated aluminum diaphragm is interposed, insulated from the aluminum electrode by a porcelain sleeve.

Alternating currents of 9 amp. at 4 v. gave a good yield of sodium under careful temperature regulation, with very little corrosion of the aluminum.

Cost Data on Castner Process

In 1906 C. F. Carrier published the following figures and facts concerning the Castner process:

Advantages:

Low melting point of bath.
Simplicity of the apparatus.

Disadvantages:

High cost of raw materials.
Low ampere efficiency.
Small size of the units.
Constant explosions during process.

Ampere efficiency is theoretically 50 per cent, since for every atom of sodium liberated an atom of hydrogen must also be formed.

The metal is removed in driblets by dipping out with a spoon, so the latter item may be a considerable factor.

COST FIGURES (1906)

Daily production	1 ton of sodium
Ampere efficiency	40 per cent
Fall of potential	5 v. per cell
Capacity of cells	1,200 amp.
Capitalization	$30,000

360 days per year; 24 hours per day.

COSTS PER YEAR

650 tons NaOH @ $45	$29,250
725 hp.-yr. @ $20	14,500
Thirty men @ $2 per day per man	21,600
Management and expert labor	9,000
Interest and depreciation (15 per cent)	7,500
General expenses and selling, 5 per cent of sale price	9,000
Miscellaneous supplies	1,000
Total	$91,850
Yearly production, 720,000 lb.	
Approximate cost per lb.	12.7c.

In 1905 Edgar A. Ashcroft invented a cell in which he electrolyzed fused soda in one compartment with graphic anode and molten lead cathode; in the second, to which the sodium alloy flowed, he used the above-mentioned alloy as anode and a nickel rod as cathode. By suitable means for controlling the temperature of the alloy, he claimed the possibility of running the process with a bath of molten caustic soda in the second cell.

His current density was 2 to 10 amp. on the anode surface and 10 amp. on the cathode surface; his voltages 8 in the first compartment and about 2 v. in the second. He claimed current efficiencies of between 80 and 100 per cent in both cells under properly regulated conditions.

The lead, after electrolytic separation of the sodium, entered the first compartment for a fresh charge. The idea was novel, but does not seem to be operating on a very large scale.

Fitzgerald described the Castner process as operated by the Niagara Electro Chemical Co. at Niagara Falls, N. Y., under the management of the Roessler & Hasslacher Chemical Co., pointing out particularly the manufacture of oxone from fused sodium peroxide. When treated with water 1 lb. of this substance yields 2.08 cu.ft. of oxygen gas, a fact which has led to its general use in hospitals as a reliable source of gas for resuscitation.

Carrier Fused Salt Cell

C. F. Carrier in 1906 patented a cell in which he electrolyzed fused salt. (See Fig. 2, taken from U. S. Pat. 830,051; Sept. 4, 1906.) For this purpose he had the anode compartment equipped with graphite anodes and the cathode compartment, which was on the other side of a division wall, equipped with a flat iron plate for cathode. The intermediate electrode was molten lead, which was caused to flow back and forth by the action of two heavy plungers.

The melt in the cathode chamber was fused caustic soda kept just a little above its melting point. The cell was started by piling a little salt around the anode, which was lowered almost to the lead (the latter being in molten condition). When an arc had been formed between graphite and lead, some of the salt melted from the intense heat, and by gradually drawing the anode away from the lead and feeding in salt the bath was built up. Care had to be exercised at this time not to pass the current through the cathode, otherwise the lead would be attacked due to absence of sodium.

When, however, the bath was partly built up, the current was put through the regular channels.

The sodium was deposited in the lead, which conveyed it to the cathode compartment, there to be set free at the iron cathode and collected under paraffine after its exit from the overflow pipe.

To prevent shorting of the current from cathode to

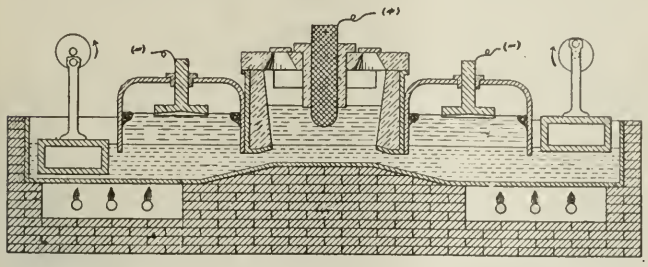

FIG. 2—CARRIER FUSED SALT CELL

bell-covering compartment, a water-cooling pipe was placed on the inner edge of the bell-shaped top of the cathode compartment. This permitted the bath to be kept in solid condition, and hence a good insulator.

One of the chief difficulties which seems apparent in this type of furnace is the control of temperature in the furnace. In spite of the inventor's claims to regulation by means of the water cooling, there still remains the fact that the temperature must drop from about 800 to 300 deg. C. in the space of a few inches. It has also been found that the iron castings do not hold lead tightly and are subject to deterioration, hence it seems like placing too many eggs in one basket.

Darling Process Using Sodium Nitrate

J. D. Darling had meanwhile invented a process for making metallic sodium from sodium nitrate, carrying on the experimental work at the Philadelphia plant of Harrison Bros. & Co., Inc. Fig. 3 represents the cell as described in U. S. Pat. 517,001; March 20, 1894.

For anodes he used carbon or platinum rods set in compartments with perforated inverted bell of aluminum enveloping them. This bell was fitted with perforations sloping down from the inside to prevent the outward flow of the gases generated during electrolysis. The iron pot served as cathode, air being excluded by a tight cover. Sodium nitrate was melted in the pot, the top cover and electrodes were set in place, and the current was turned on. The molten nitrate was reduced to nitrite of soda with the addition of sodium oxide, the latter dissolving in the nitrite of soda. The nitrite of soda and the sodium oxide were then decomposed, permitting the liberated sodium to float to the top of the bath and pass down through a suitable outlet pipe. Gaseous NO_2 and O_2 passed off through an opening in the top of the anode chamber and were led through absorption bottles containing water, thus forming nitric acid and permitting the oxygen to escape.

He later invented a porous diaphragm of portland cement and improved his cell, and attempted to market his process. Unfortunately the explosion hazard was too great a drawback, and the process was abandoned about the year 1905.

Mixed Baths Containing Fluorides

In 1907 Seward and von Kügelgen got out five patents covering bath mixtures and parts of apparatus for making metallic sodium from salt.

The first bath mixture consisted of 4 parts $CaCl_2$, 2 parts NaF and 1 part $BaCl_2$ and was considered a great improvement over previous mixtures, which included potassium salts, because the latter contaminated the sodium metal. This bath melted below a red heat and was advantageous because the alkaline earth metal was not decomposed by the potential used.

The second mixture was composed of 15 parts of calcium and sodium fluorides combined with 100 parts NaCl. It was found to have a much lower melting point than NaCl, and the fluorides had a higher decomposition voltage, hence were practically unconsumed.

The first cell consisted of an iron vessel containing a bath of molten salt. Instead of an iron bottom this pot had one of firebrick or magnesia brick. The anode consisted of the walls of the iron pot and the cathode was molten lead in the bottom of the brick furnace. Halfway down in the cell was an iron wire diaphragm set horizontally in the brickwork so as to separate the anode from the cathode compartment.

During electrolysis the sodium collected on the surface of the electrode and flowed down through an overflow pipe to an outside container; the chlorine attacked the lead, forming lead chloride, which, being heavier than salt, remained at the furnace bottom and was drawn off by a suitable pipe.

One of the main objections to this type of cell is the difficulty of construction and operation. The diaphragm is set rigidly in the furnace walls and cannot be removed

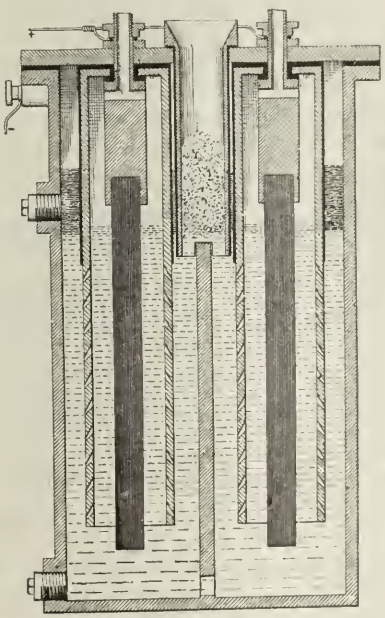

FIG. 3—DARLING CELL USING SODIUM NITRATE

without tearing down the furnace. There is always a large body of sodium on the surface of the bath, which is objectionable.

The second cell consisted of an iron pot as anode lined with magnesia brick at the bottom and fitted with graphite blocks at the top. The cathode is set in the center of the pot surrounded by a water-cooled casting, an arrangement which caused salt to remain molten on the walls of the cathode compartment and prevented leakage and corrosion.

In 1909 G. Van Hevesy made a study of the electrolysis of fused alkalis with especial reference to the

solubilities of the alkali metals in the melt, and arrived at the following tables:

SOLUBILITY OF Na IN NaOH

Temperature, Deg. C.	Grams Na in 100 g. NaOH
480	33.3
500	10.1
610	9.9
670	9.5
760	7.9
800	6.9

SOLUBILITY OF K IN KOH

Temperature, Deg. C.	Grams K in 100 g. KOH
480	8.0
700	1.0

In spite of the rapidly decreasing solubility of the Na and K at higher temperatures, the electrochemical efficiencies in electrolysis of NaOH and KOH rapidly decrease with rising temperature as a result of the increase of velocity with which the metal diffuses into the molten electrolyte.

Measurements show this velocity to be greater for sodium than for potassium, and in the former case to increase rapidly above 340 deg. C., at which point the efficiency for NaOH electrolysis sinks nearly to zero.

Action of Fused Caustic on Metals

At about the same time LeBlanc and Bergmann made a study of the influence of metals on fused caustic, which gave an idea to the chemical engineer as to what to expect in the construction of cells for electrolysis of this chemical.

For the tests they prepared NaOH which analyzed as follows: NaOH, 92.6 per cent; Na_2CO_3, 4.95; H_2O, 2.45. Minor impurities neglected.

The carbonate was not taken out, for the caustic in general use contained about 5 per cent and the tests were not to be made for a special product.

They found that:

Silver is attacked by NaOH.

Gold is not attacked.

Copper is not attacked by NaOH at 435 deg. C., but at 563 deg. C. there was a noticeable reaction which increased at higher temperatures.

Iron does not react with NaOH in a marked manner at 400 deg. C., but at 700 deg. C. the reaction is very lively. After cooling, the melt appears dark red and leaves a dark red precipitate on solution in water.

Copper, on the other hand, leaves a dark blue precipitate.

Nickel does not react with NaOH at 400 deg. C., but at higher temperatures it reacts with the formation of a green melt which yields a black residue in water.

Platinum does not react at 400 deg. C., but is somewhat soluble around 700 deg. C. The melt on solution in water leaves behind a black residue.

Zinc acts on NaOH with generation of water and the residue consists of $Zn(OH)_2$.

Aluminum is slightly attacked by NaOH at temperatures ranging from 450 to 500 deg. C.

Magnesium reacts with NaOH at 400 deg. C. in a nickel crucible in a very vigorous manner.

Sodium had to be tried in a nickel crucible, since gold is dissolved in molten condition. It reacts with NaOH at 450 deg. C. in a slight manner, and more vigorously at 550 deg. C. The water solution was made without any gas evolution.

Their results may be summarized as follows:

Caustic soda is easily dehydrated at 400 deg. C. in a gold crucible and atmosphere of nitrogen.

Of the metals investigated, gold alone did not act on NaOH in that temperature range on exclusion of air.

Silver and sodium react with hydrogen generation; platinum, copper, iron, nickel, aluminum, zinc and magnesium with hydrogen generation and splitting off of water.

This double reaction is explained in the simplest manner by the existence of the metal and sodium oxide compound from the reaction $Me + xNaOH = Me(ONa)_x$ with Na_2O, the final product, being a more or less complex one in which water is split off according to the reaction

$$2NaOH = Na_2O + H_2O$$

Danckwardt invented a cell in 1898 containing two compartments, the positive of which was double walled and provided with water cooling. He melted the charge of salt by means of fuel gas and air, or charcoal and air, removed the chlorine through a pipe with a damper in it, and permitted his sodium to rise to the surface in the cathode compartment and flow by gravity into a container. The apparatus was rather complicated and so far as known was not used on a large scale.

In 1910 R. J. McNitt (with whom the author was associated) patented a process for making sodium-lead alloy in the Acker type of furnace and then recovering the metallic sodium by distillation of the alloy under vacuum. This was partly successful and yielded a good grade of sodium.

In 1912 H. Mehner patented a process of reacting sodium carbonate with molten cast iron, which was not electrochemical but of scientific interest.

Marguet in 1913 obtained a French patent in which he said that neither the impurities of the caustic soda bath nor the depositions on the cathode constitute the cause of the drop in yield. It is caused solely by the excessive temperature rise occasioned by re-solution of sodium in the electrolyte.

Seward and von Kügelgen sought to improve their process by purifying the electrolyte before use in making sodium. They found that small masses of impurities in the salt tended to conduct the current between the poles of the cell and hence defeat the purpose of electrolysis.

By fusing the impure salt and subjecting it to a low current density and high potential, they were able to cause the less electropositive particles to separate out in the bottom of the furnace. The pure salt was then bailed out and used for the final bath.

Effect of Adding Sodium Carbonate

B. Neumann made some experiments on mixtures of NaOH and Na_2CO_3 in 1914, getting melting point curves showing the varying current efficiencies for his mixtures. The best yields of sodium (83 per cent) were obtained on the addition of 12 to 17 per cent Na_2CO_3, the melting point of the mixture being 280 deg. C.

He also made observations on mixtures of NaOH and NaCl, but the yields were lower than with Na_2CO_3 additions or with pure NaOH. In the best run only 39 per cent current efficiency was obtained, with 5.5 per cent NaCl and melting point of 285 deg. C. He stated that higher efficiencies in the production of sodium in technical practice could be obtained by the careful dehydration of the fused caustic before electrolysis, by the use of NaOH free from NaCl, by the addition of Na_2CO_3 to lower the temperature of the bath, by careful temperature measurements, which until now have been regarded as unnecessary, and by greater attention to the anodic separation of water.

The melting point drops from 296 deg. C. for pure NaOH to 280 deg. C. for the NaOH-Na_2CO_3 mixture containing 17 per cent Na_2CO_3, rising again to 297 deg. C. for 30 per cent Na_2CO_3.

The current efficiency rises from about 25 per cent at 2 per cent Na_2CO_3 to a maximum of 63.03 per cent at 17 per cent Na_2CO_3, decreasing again to 40 per cent at 27 per cent Na_2CO_3.

At the maximum current efficiency the range of temperature between freezing and overheating is also a maximum, being 16 deg. Above this concentration of Na_2CO_3 the temperature range gradually diminishes and a factory using these strengths can run with only low efficiencies, if at all. The voltage between the electrodes in this mixture amounted to an average of 6 v.

Caustic soda is found in the industries usually accompanied by some NaCl, sometimes up to 3 per cent. Naturally, in continued electrolysis the salt content increases in the cell, since the decomposition point of salt at 300 deg. C. (likewise that of Na_2CO_3) is about 1 v. higher than that of NaOH. The consequence of continued increase of salt content is poorer yields and the necessity for finally discarding the bath.

It was found that in mixtures of salt and caustic the melting point decreased from 289.3 deg. C. with zero salt to a minimum of 283 deg. C. with 7 per cent salt, then rose rapidly to 315 deg. C. with a 15.6 per cent salt content.

Von Wartburg found that no chlorine was generated at the anode with mixtures containing from 25 to 50 per cent NaCl.

In 1915 Ashcroft invented a cell in which he made sodium-lead alloy from mixed chlorides of sodium and potassium, and then extracted the potassium by addition of a sodium salt, NaCl or $NaNH_2$. The alloy was left with almost pure sodium, and was subjected to electrolysis in a second cell, where the sodium metal was recovered at an iron cathode, the alloy acting as the positive pole.

This was quite an ingenious invention, but, like a great many of the similar sort, very complicated. There were arrangements for stirring the molten salt by the swirl of the current, transfer of the alloy through an intermediate vessel to the second cell and return after impoverishing it of the sodium metal.

Acker in 1915 invented a new process in which he used Ashcroft's idea of the sodium-lead alloy as intermediate electrode, but substituted for NaOH as bath in the second cell cyanide or cyanamide of sodium. By this bath he claimed great improvements in efficiency.

Improvements in Fused Salt Process

Seward and von Kügelgen obtained patents on improvements in the production of sodium in which they used a shallow cell with graphite anodes set in a ring and stationary iron hollow cathodes set in the furnace bottom and projecting upward to the top of the anodes. (See Fig. 4, which is taken from U. S. Pat. 1,092,178; April 7, 1914.)

On the upper end of the cathode was a nipple for catching the sodium as it overflowed, and covering the cathode space was a head of cast iron suitably projected within the bath by salt maintained in frozen condition by a watercooler encircling the lower edge of the hood. In this way the sodium was prevented from oxidation and allowed to flow through the cathode to a container placed beneath the cathode. The pressure within the cathode hood and the container beneath was maintained the same by connecting the two with a pipe, and any excess pressure due to hydrogen formation was relieved through an oil seal.

A later development of the cathode was one consisting of a double jacket, joined only at the top, the space between being filled with asbestos wool or some other suitable material. This improvement was to avoid the magnetism caused by the current passing in one direction and holding the sodium against the side of the cathode. In the new cathode the current had to pass upward and then downward, thus destroying the magnetic effect.

Seward made a very thorough discussion of the process of making metallic sodium from fused salt, which is abridged as follows:

> For melting the bath in the furnace an alternating current is best, since it avoids the generation of sodium and chlorine gas, until the bath has been built up to the level of the sodium collector. In this way the bath is uncontaminated except from the impurities of the graphite, which may be burned off shortly after start of electrolysis.

An electrolyte melting at about 600 deg. C. was used preferably, with an operating temperature 630 to 679 deg. C., suitable fluxes being added to maintain this

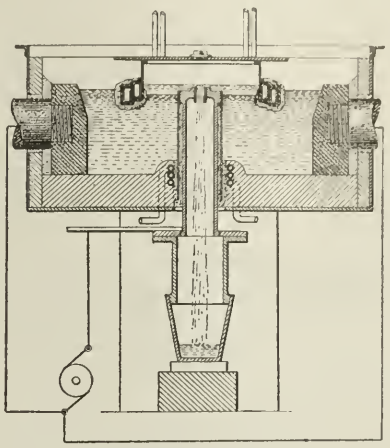

FIG. 4—SEWARD AND VON KÜGELGEN FUSED SALT CELL

melting point. Practically nothing but NaCl is electrolyzed, but after a long time there is some slight volatilization and decomposition of the fluxes, necessitating addition of fresh material. After the direct current has replaced the alternating current the output is poor until all moisture is eliminated from the lining, etc., and the electrolyte is completely dehydrated.

The process requires little attention beyond keeping the electrolyte at the proper level and temperature and periodically tapping the sodium from the receiver. Occasionally the appearance of sodium in the anode compartment indicates that the condition of the curtain or of the crucible bottom has become abnormal and corrective methods must be applied. The appearance of sodium outside of the curtain may also indicate that accumulated impurities on the crucible bottom have become active and are separating sodium so remote that it rises outside the sodium chamber. A preliminary refining of the salt, however, renders the accumulation of impurities so slow that this condition appears only at long intervals.

Developments Since 1916

J. Brode patented a cell in 1916 in which the anode compartment consisted of a pot lined with firebrick in which were set graphite anodes. The cathode compartment was a bell of iron submerged in the molten salt. The top was airtight, but the lower part was perforated to let the electrolyte circulate with the current. By maintaining a definite pressure inside the cathode chamber the sodium was permitted to rise to the top and flow down into a container which was under slightly less pressure. This apparatus runs into complications in

way of keeping the proper pressure and in being compelled to tear down the furnace to replace the diaphragm.

Pfleger and Ott patented a cell, which was a duplication of the Castner cell, in which they proposed to place a wall of solid salt between the anode and cathode chambers. This was maintained by passing a cool gas through a hollow partition wall which carried the diaphragm.

R. J. McNitt patented in the same year a furnace for making metallic sodium, in which he brought the sodium in molten state to the container by putting the top of the bath under pressure of a neutral gas, such as nitrogen. By this means he claimed to raise the boiling point of the sodium well above its normal value. Sodium boils normally very close to the melting point of salt, and consequently was very likely to be formed in a gaseous cloud during electrolysis. The sodium was permitted to rise inside a hood of iron which carried an iron diaphragm, and flowed down into an external container.

In 1917 McNitt took out a second patent in which he applied the pressure to the zone of electrolysis by means of a superimposed column of molten electrolyte. This cell, described in U. S. Pat. 1,219,808; Feb. 6, 1917, is shown in Fig. 5.

In 1920 Smith and Veasey at the Dow Chemical Co.'s plant in Midland, Mich., got out a process in which they used Na_2CO_3 with NaCl in the proportions of 35.6 parts NaCl to 64.4 parts Na_2CO_3, giving a melting point of about 600 deg. C.

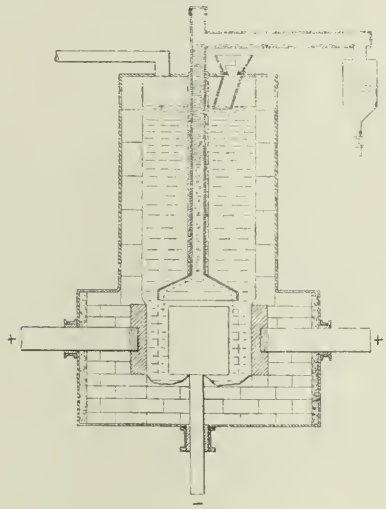

FIG. 5—McNITT CELL

During the years 1917 to 1919 the writer performed a series of experiments on the manufacture of metallic sodium from molten salt at the plant of the Semet Solvay Co. in Syracuse, N. Y., and built furnaces of various designs for the study of the different elements entering into sodium production.

Work along these lines is being investigated by many companies, and the future is bound to bring out new salt processes to compete with the old Castner process, which has almost reached its maximum efficiency.

Of recent years the general dislocation of price levels and labor rates has changed many commercial processes into uneconomical operations, and the production of metallic sodium is no exception. However, the writer believes that the salt process will eventually supersede the caustic soda process, on account of the cheapness and non-corrosiveness of the raw material.

Part II will be published in a subsequent issue.

Electrothermic Zinc Developments

By T. M. Bains, Jr.

SINCE the suspension of experimental work at East St. Louis[1] in 1917, little has been done in dry electrothermic smelting of zinc ores. Further research on zinc condensation was carried on at Case School of Applied Science by C. H. Fulton.

In the fall of 1920 the writer again took up some of the problems which baffled us at East St. Louis and last spring worked out the following improvements:

1. Use of one size of briquet for both cross-connectors and columns, of square or rectangular cross-section.
2. Twelve column set-up of these briquets, for single delta, double "Y" and double delta operation, three phase.
3. Electrodes entering the retort through the top, instead of bottom.
4. Elimination of the costly variable voltage equipment, replacing same by standard transformer equipment.
5. Use of refrax carborundum brick for heating of the condenser.

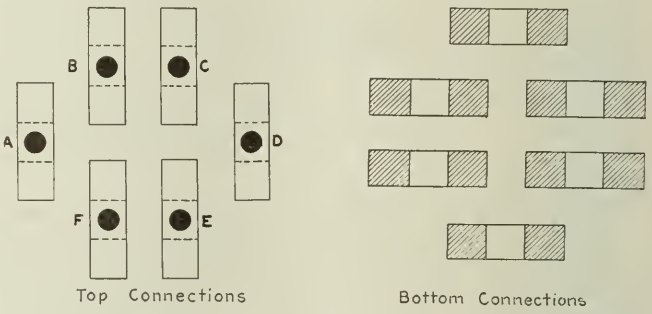

FIG. 1—SKETCH OF CONNECTIONS BETWEEN RESISTORS

By the first improvement, the set-up contains no Acheson graphite or carbon connectors or any material except the briquets. The large, costly graphite connectors used at East St. Louis shown in previous papers were therefore eliminated. By using square or rectangular briquets for cross-connectors and the same size briquets in the columns, a great improvement has been made. The new set-up is shown in Fig. 1. It will be noted that this set-up consists of twelve columns, connected both top and bottom. As the raw briquet on heating softens at about 150 to 200 deg. C. due to the melting of the pitch binder, a height of 6 ft. is probably the maximum limit that can be baked in place. So should a higher set-up be desirable, the baking must be done in two or more steps. The assembly could be considered as made up of "U"-shaped blocks; the lower set of six set bottom down, and the upper set of six set bottom up, on top but rotated through 90 deg. The upper and lower portions of the set-up are identical, except oriented 90 deg. on each other. Briquets of square cross-section are therefore preferable. With this design, the lower half after baking to about 400 deg. C. is strong enough to withstand the weight of the upper half. The latter can be baked in place on top of the lower half.

Electrodes of graphite or carbon are brought through the top of the retort hood and contact is made at the central part of each cross-connector. The base is therefore solid and smooth, instead of containing electrodes,

[1] "Electric Resistance Furnace of Large Capacity," by C. H. Fulton, *Trans.*, A.I.M.E., vol. 64, p. 188; Chem. & Met. Eng., vol. 22, p. 73; p. 130 (1920).

which must be prevented from oxidizing, when the distilled briquets are removed. Also the electrode "jacks" used at East St. Louis are eliminated.

By the use of six electrodes, one at the center of each of the top connectors, three different connections are obtainable in a three-phase furnace. These are, first, single delta, with four columns in series per phase by joining lines to *A*, *C* and *E*; second, double "Y," with two parallel circuits of two columns each per leg of the "Y" by joining lines to *A*, *C* and *E* and connecting *B*, *D* and *F* as a neutral point; and third, double delta, with two parallel circuits of two columns each across each phase of the delta by joining lines to *A*, *B* and *C*, and connecting *A* to *D*, *B* to *F*, and *C* to *E*. By changing from one set of connections to another and with standard transformers, with 2,300-volt primary and 115/230-volt secondary, from 5.6 to 133 amp. would flow through the briquets, assuming each briquet has a resistance of 1 ohm and that the primary 2,300-volt potential is held constant. The automatic control of current and voltages has been worked out by L. F. Woolston, of the General Electric Co.

Heating the condenser above the melting point of zinc, 418 deg. C., has been a difficult problem. Zinc vapor attacks all metal so far tried, and thus electrical resistors of the nichrome type cannot be used. Carbon and graphite heating elements have been failures. Refrax carborundum brick is not affected by zinc vapor and has been successfully used here. This type of heater was described in the *Engineering and Mining Journal-Press* of April 1, 1922.

Experiments in producing sponge iron from refractory ores high in iron have shown that the residue from the distillation of the zinc contains all the other metals in the form of alloys, principally as ferrosilicon. By crushing this residue and adding it to a $CuSO_4$ solution, slightly acidified, the metals in the residue are thrown down with the cement copper and can thus be regained with the copper. It is simpler, however, to use the residue as part of the charge to the lead or copper blast furnace direct.

Prospects of Polish Steel Industry

The future of the iron and steel industry of Polish Upper Silesia, while apparently assured after a few years, is not regarded as optimistically for the immediate future as that of the coal industry, says Colonel A. B. Barber, technical adviser to Poland, in a statement received by the Department of Commerce. This is due to the fact that a considerable part of the production must at present seek its market in Germany, while in the German market there is the difficulty which existed even before the war of meeting west German competition, chiefly on account of the long distance the greater part of the iron ore must be hauled to Upper Silesia and on account of the inferior strength of Upper Silesian coke when used in blast furnaces (200 tons being a maximum charge as against over 400 tons with Westphalian coke). It is reported that today Westphalian pig iron can be laid down in Upper Silesia at a price lower than Upper Silesian pig iron. The Polish Silesian iron and steel industry will therefore for some time be dependent upon the condition of the industry in Germany, and to secure the Polish market will at times require protection by customs barrier against the German industry.

For the future, however, the prospects of the entire Polish iron and steel industry depend fundamentally upon the development of an increased demand for iron and steel in ex-Russian Poland, Galicia and neighboring territories (Russia, Rumania, etc.). Before the war the Russian tariff against pig iron was $15 a ton and against semi-finished iron products $85 a ton. The annual consumption of iron products in ex-Russian Poland was less than 20 kg. per inhabitant. The use of iron products in Galicia shows only a little less retarded development. The per capita consumption in ex-Prussian Poland, on the other hand, amounted to 80 kg. per annum, in France 90 kg., in Germany 140 kg. and in the United States 300 kg. It seems that an increased demand for iron and steel is likely to develop and if this should reach 60 kg. per inhabitant for all of Poland the amount of iron and steel required annually would be 1,700,000 tons. This is more than the entire production of Poland, including Polish Upper Silesia, leaving out of consideration the demand from Russia and other neighboring countries.

Iron-Ore Production Diminishing

While the iron and steel production of Upper Silesia as a whole during the past decade has been constantly in the neighborhood of 1,250,000 tons per annum (of which 70 per cent on the Polish side), the Upper Silesian iron ore production is rapidly becoming insignificant, having fallen to 53,000 tons in 1920. In 1912 the production was 165,000 tons, having decreased steadily from 706,000 tons in 1891.

Upper Silesia has always had to import the essential high-grade ore from Sweden or south Russia, and in recent years, owing to the exhaustion of the Silesian ores, has imported the greater part of her low-grade ores from Germany, together with up to 300,000 tons annually of scrap iron. Polish Upper Silesia will have to continue importing her high-grade ores, but it is expected that within 2 or 3 years the production of ore in the part of Congress Poland lying just to northeast of Upper Silesia (region of Czestochowa and northwest thereof), where the reserves are estimated at 300,000,000 tons, will be sufficiently developed to take the place of the exhausted Upper Silesian and imported German low-grade ores. During the intervening years, before the supply of iron ore from Polish and south Russian mines can be developed and the use of scrap iron replaced by the use of iron ore, the greatest difficulty for the iron and steel industry in Polish Upper Silesia will be to provide the necessary ore and scrap iron to maintain the production at the present rate. However, it is expected that, in the convention now being negotiated in accordance with the Geneva decision, Germany will undertake for a limited period to continue the supply of the necessary German ores and scrap iron.

Zinc and Lead Industry

The future of the zinc and lead industry, all of which is on the Polish side, is limited by the ore available, which will be exhausted in a few decades. In 1913, the greatest zinc year, Upper Silesia produced half of Germany's zinc and one-seventh of the world's supply. Now, however, the ore production has fallen from 508,000 tons in 1913 to 266,000 tons in 1920, and this has rendered superfluous a certain portion of the capacity of the reduction plants. A few of the plants have entirely shut down, while the others are working at less than 50 per cent capacity. Despite reduced output Upper Silesia should be able to supply all Polish requirements and leave a large surplus for sale to Germany and elsewhere.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Yeast Cultivation.—The parent specification, Br. Pat. 174,625, covers the cultivation medium for distillation yeast. Nitrogen for the growth of yeast is supplied in the form of ammonium salts, or salts of amides or amines, the solution being neutral or very slightly acid. The yeast is aërated during cultivation. A suitable solution contains sugar and ammonium lactate, with sufficient lactic acid to neutralize not more than 0.3 c.c. normal soda solution per 20 c.c. of filtered culture medium.

The addition of oxidizing enzymes is covered by Br. Pat. 174,627. In cultivating yeast in a solution containing compounds of amines or amides as described in the parent specification, oxidizing enzymes are added. A suitable solution contains sugar, carbamide and oxidase. The amides or amine compounds are not necessarily added in a pure state; liquids containing them such as urine and waste waters can also be employed.

The fourth specification of the series describes the addition of the nutrient solution to a vessel containing aërated and fermenting yeast at such a rate that the nutritive substances and the alcohol produced are consumed as fast as they are supplied or formed, the concentration remaining approximately constant. Suitable solutions are (1) a wort formed from mashed maize, malted barley and malt germs, (2) a solution of beet sugar, ammonium lactate, biphosphate of potassium and magnesium sulphate. Br. Pats. 174,625 to 174,628 inclusive. Not yet accepted. N. Muskovits, Nagyvárad, Rumania. March 29, 1922.

Tanning.—Hides and skins are tanned by treatment with aqueous acid solutions of the sulphonated products obtained by condensing a carbohydrate with an aromatic hydrocarbon or carbazol or halogen substitution products thereof, the sulphonic acid groups being introduced either by effecting the condensation in the presence of sulphuric acid or by using a sulphonic acid of the cyclic component as reacting material. Natural vegetable tanning agents may also be present. According to the examples, the tanning bath consists of a sulphuric-acid solution of the sodium salt of (1) the product resulting from the condensation of naphthalene, anthracene, phenanthrene, α-chlornaphthalene, or naphthalene-β-sulphonic acid with cellulose in the presence of sulphuric acid, with or without the addition of oakwood extract, (2) the product of the condensation of cellulose and benzene or carbazol in the presence of oleum, or (3) the product obtained by condensing naphthalene with starch, dextrine or grape sugar in the presence of sulphuric acid and anhydrous sodium sulphate. According to the provisional specification, the cyclic component comprises aromatic compounds, or derivatives thereof which are free from hydroxyl. Specification 173,881 is referred to. (Br. Pat. 174,700. Badische Anilin- und Soda-fabrik, Ludwigshafen. March 29, 1922.)

Purification of Anthraquinone.—Anthraquinone is purified by solution in cresol or other homologs of phenol and crystallizing. The process may be applied to crude anthraquinone, dry or moist, or to anthraquinone made from phthalic anhydride or by oxidation of anthracene in the presence of a catalyst. The product melts at 287 deg. C. or higher. (Br. Pat. 174,784. British Alizarine Co., London, March 29, 1922.)

Ammonium Sulphate.—Neutral ammonium sulphate of good color is obtained by passing ammonia free from sulphuretted hydrogen into mother liquor drained from crystals removed from a saturator in quantity sufficient to neutralize the acid in the mother liquor and the acid in the crystals, oxidizing the solution, for instance by air, and filtering, then stirring the crystals with the purified mother liquor. The crystals are separated by settling and the mother liquor is decanted with suspended impurities and may be returned to the saturator. (Br. Pat. 174,878. South Metropolitan Gas Co., E. V. Evans and P. Parish, Bromley, England. March 29, 1922.

Sodium Hydroxide, Carbonate and Thiosulphate.—Hydrated sodium sulphide, reduced to powder, reacts with air or oxygen at ordinary temperatures, in the presence of finely divided active charcoal, to give a product containing chiefly caustic soda and sodium thiosulphate. Charcoals sold under the registered trade marks "Eponit" and "Norit" are very active, but fine anthracite coal, animal charcoal and charcoal obtained by the low carbonization of wood, coconut shell, etc., after being activated by treatment with air or steam at low temperatures, are also suitable. If air is employed, the residual nitrogen may be collected as a by-product. After the reaction, the resulting mixture is treated in one of the following ways: (*a*) The solution obtained by extraction with water is filtered, concentrated and cooled when crystals of thiosulphate and a mother liquor of caustic soda are obtained. The charcoal, after washing, may be used again. (*b*) The product is leached with alcohol to extract the caustic soda, and then with water to extract the thiosulphate. (*c*) The solution obtained by lixiviation with water is treated in the cold with carbon dioxide to precipitate the bicarbonate and leave a solution of thiosulphate ready for crystallization. If the carbon dioxide is passed into the hot solution, a mixture of sodium carbonate and thiosulphate is obtained, which is separated by fractional crystallization. (*d*) The solution, containing from 10 to 40 per cent of sodium compounds, obtained by extraction with water, is electrolyzed, when a solution of caustic soda is obtained at the cathode, and a dilute solution of sulphuric acid and a loose precipitate of sulphur are obtained at the anode. In an example, sodium-sulphide crystals are ground and well mixed with an equal quantity of active charcoal, in an apparatus provided with a water-jacket to prevent the temperature exceeding 100 to 200 deg. C. Steam is evolved and the reaction is allowed to proceed until lead acetate gives a white precipitate with the solution of the product. The latter is extracted with water and subjected to fractional crystallization. (Br. Pat. 174,653. E. E. Naef, W. Bridgford, England, March 29, 1922.)

Reducing Manganese Ores.—A process for the production of manganese or manganese alloys low in carbon and silicon from ores in which the principal manganese content is of a higher degree of oxidation than MnO comprises first smelting the ore with such a proportion of carbon that the manganese is reduced to the form MnO, whereafter the ore is finally reduced with silicon, which may be used in the form of silicomanganese or ferrosilicon. Other oxides such as iron oxides present in the ore may be reduced in the first stage by increasing the amount of carbon. Phosphorus may be similarly reduced, iron being added, if necessary, to combine with it. The amount of manganese in the slag formed on reduction with silicon may be diminished by adding lime with the silicon, or by adding lime or limestone to the ore before smelting with carbon. Silica also may be added. (Br. Pat. 174,923. Not yet accepted. Aktiebolaget Ferrolegeringar, Stockholm. March 29, 1922.)

Borax and Boric Acid.—A mixture of sodium pentaborate and a sodium salt is treated with ammonia, borax being formed and crystallized. The borax in the mother liquors serves to liberate the ammonia for re-use with formation of boric acid, which is drawn off and the remaining ammonia (if any) liberated by addition of lime. Calcium borate is recovered as usual. In examples, the theoretical amounts of pentaborate and sodium chloride are dissolved in water at 40 deg. C. and the theoretical quantity of ammonia added. The borax is then either crystallized as much as possible by cooling and the ammonia recovered by lime, or the theoretical amount of borax required to liberate the ammonia is left in solution and the latter boiled, the boric acid separating out. (Br. Pat. 175,201. A. Kelly and R. B. R. Walker, London. April 5, 1922.)

Tanning.—Mineral-tanned leather is retanned with organic tanning agents in three stages. After rinsing to remove any uncombined mineral salts, the leather is placed in an organic tanning solution of about 50 deg. Bé., the acid formed in the reaction being continually neutralized with alkali until permanent neutralization is obtained. The second stage consists in treating the product with a solution of an alkali salt of an organic tanning matter until it is thoroughly saturated. The substances incorporated in the leather are finally precipitated by reaction with a corresponding quantity, ascertained by analysis or otherwise, of a solution of neutral or alkaline chromium, iron or aluminum salts, so that the final product does not contain any uncombined metal salts. The leather thus obtained is allowed to rest for a few days, is then rinsed and treated in the usual manner. (Br. Pat. 173,508. Not yet accepted. J. Byston, Holstein, Germany. Feb. 22, 1922.)

Purifying Lactic Acid.—The lactic acid or lactate to be purified is first converted into magnesium lactate either by effecting the lactic acid fermentation in presence of magnesium compounds such as carbonate, hydroxide or oxide, or by double decomposition of the more easily soluble lime compound or other soluble lactate with a suitable magnesium compound such as sulphate. The acid is then liberated either by direct acidification with sulphuric acid and extraction with acetone, ether, etc., or the magnesium lactate is suspended in acetone or ether and then agitated with sulphuric acid when magnesium sulphate separates and the solution of lactic acid is evaporated. The product in each case may be purified with bone-black. In examples, commercial lactic acid is treated with magnesia and the resulting lactate treated by each of the above-described methods. (Br. Pat. 173,479. Not yet accepted. J. Schatzkes, Berlin. Feb. 22, 1922.)

Celluloid Sheeting as Glass Substitute.—A sheet material applicable as a substitute for glass is made by incorporating a cellulose ether, such as ethyl or benzyl cellulose, or a composition containing the same, with an open-meshed metallic or textile fabric, or with wires, cords, strips, etc. The cellulose compound may be in solution or melted at a temperature of 180 to 200 deg. C. (Br. Pat. 173,021. H. Dreyfus, London. Feb. 8, 1922.)

Alkali Cyanides.—Alkali cyanides are produced by passing hydrocyanic acid or gases containing it into a solution of an alkali salt and mixed with lime, the acid radical of the salt being one that forms an insoluble calcium salt. Sodium carbonate and sulphate are suitable, and it is preferred to use a small excess of lime. (Br. Pat. 174,364. Not yet accepted. Deutsche Gold- und Silber-Schneide Anstalt vorm. Rössler, Frankfort-on-Main. March 22, 1922.)

Hydroquinone.—Hydroquinone is manufactured by reduction of quinhydrone by heating either with aqueous ferrous sulphate and an alkaline earth carbonate, or with metallic iron and water. Quinone may be half reduced in the ordinary way and the reduction then completed as described above. (Br. Pat. 174,554. W. Carpmael, London. March 22, 1922.)

Book Reviews

MATERIALS OF CONSTRUCTION, THEIR MANUFACTURE AND PROPERTIES. By the late *Prof. Adelbert P. Mills.* Second Edition. Edited by *Prof. Harrison W. Hayward,* Massachusetts Institute of Technology. New York: John Wiley & Sons, Inc., 1922. Price $4.

Six years ago the reviewer was faced with the problem of teaching metallurgy to engineering students. He assumed that the subject would appeal to them better if presented from the viewpoint that metals are very important materials of construction, and wide differences in properties and general dependability result from differences in the smelting processes, in the chemical analysis and the physical constitution. Young engineers can easily be convinced that they should know something of these things in order to make intelligent selection of materials which they will some time build into bridges, transmission lines, lathes or autoclaves.

That decision made, the next thing was to find a text book which described both the metallurgy of metals and alloys in the light of modern scientific developments, and their physical properties. Fortunately, Mills' "Materials of Construction" was just off the press; it seemed to cover both the ferrous and non-ferrous alloys in a comprehensive and accurate manner; in fact, it was a veritable godsend.

Now comes the second edition, delayed by Prof. Mills' untimely death. Prof. Hayward has taken great pains to correct the scattered errors in the first edition. Most of the text has been reset. A 30-page chapter on the proportioning, mixing, placing and waterproofing of concrete has been written by Dean Peabody, Jr., while about the same space is occupied by Prof. G. B. Haven in new sections on fiber and wire rope and mechanical fabrics. These are about the only additions. All the text has been gone over with a long blue pencil, so that the new edition has 450 pages against 650 for the first—a cut doubtless necessary to enable the publishers to reduce the selling price to $4. Such a reduction may give the book a greater sale and thereby increase its usefulness, but will not tempt the owner of the first edition to replace it with a copy of the second.

Since nearly three-quarters of the text is devoted to metallic materials of construction, this portion has suffered most from condensation. At the outset it must be said emphatically that what there is of it is good. It contains very few archaic ideas or incorrect statements such as "Cold-working is beneficial because it closes up the grain of the metal; it also increases the cohesion and adhesion of the crystals," "Most blast furnaces are now equipped with air-drying plants," and that the Domnarfvet and Heroult (California) furnaces are the same. Fortunately, also, the admirable section on non-ferrous metals and alloys has not been compressed very much, and some notes on new alloys like duralumin have been added.

It is too bad, however, that, since the text was to be reset, opportunity was not taken to discriminate between the steels now being used and those which have not yet been adopted. Prof. Mills' concise text seems merely to have been more highly compressed. If space was desired, is it not a shame to get it by cutting down alloy steels to twenty pages, and yet give three to the basic bessemer process, and a few more to details of Stassano and Kjellin electric furnaces? Certainly such widespread and increasingly important materials as alloy steels should not be slighted in favor of foreign processes and furnaces of interest only to expert metallurgists.

Alloy steels have made great advances in the 8 or 9 years since Prof. Mills prepared his original manuscript. He then had to rely largely upon published studies of alloy systems for his data; many of these analyses have not yet found a place in industry. This new edition has not made use of the voluminous literature appearing since that time, and seemingly assumes that all these analyses have, or will have, considerable use, and thus gives the student an entirely erroneous impression on the present state of the art. For instance, considerable space is given to chromium steels ("chrome steel" in the text), while the more important nickel-chromium steels are confined to a half-page tabulation of physical properties of various analyses in the "normal" and "quenched" condition—no indication of the tremendous possibilities of correct heat-treatment. Again, tungsten steels are discussed as though they were used alongside of nickel steel, and only the merest hint that their real importance is as cutting tools, in which, of course, tensile strength is only of minor importance. Furthermore, molybdenum steels containing 1 to 8 per cent Mo are described, whereas the important commercial steels contain less than 1 per cent.

Unfortunately, the only real shortcoming of the first edition has not been corrected. Whereas steel in the abstract is discussed in considerable detail, giving clearly the effect of different impurities, constituents and heat-treatments, nothing is given about those particular kinds of steels which enter into engineering construction in great quantity. Millions of tons of rails, structural shapes,

plates, pipe, steel castings, drop forgings and galvanized sheet are made every year; but not a word can be found about any of these things; no information on the analysis, heat-treatment and properties of steel castings, or on the qualities desired in steel rails or bridge members and how to get them. And until college text books and college instructors talk a lot about steel in particular, as well as steel in the abstract, construction projects will be 10 years behind metallurgical progress, civil engineers will design shapes which cannot possibly be rolled of sound metal, and specifications such as the following will continue to be written (copied):

"Bridge pins over 7 in. diameter shall be forged and annealed; if over 9 in. diameter they shall have a 2-in. hole bored through the center"! E. E. THUM.

THE ELEMENTS OF FRACTIONAL DISTILLATION. By *Clark Shove Robinson.* International Chemical Series. New York: McGraw-Hill Book Co., Inc. 205 pp., 41 figures. Price, $2.50.

At least once a year the industries ask the question, "Why do not our universities turn out capable chemical engineers?" The question has been answered in a hundred different ways, but there is one answer that persists year after year. It is, "There are only a few teachers with fundamental knowledge of the subject and with the ability and courage to work out the essential principles and publish the facts."

Prof. C. S. Robinson of the Massachusetts Institute of Technology has had the opportunity to work in the field of distillation. He has realized the need for basic research and with a nice appreciation of the underlying principles he has made a genuine contribution to the science of chemical engineering.

It is true that Prof. Robinson's book on distillation is not a complete work, but it is a solid foundation upon which to build and it is the first time that a book of its kind has ever been written in any language. There are times when, perhaps, the reader wishes a little more could be said on some phase of the subject, but like a wise host, Prof. Robinson does not allow his guest to leave the table with a stuffed feeling but rather with a comfortable feeling of satisfaction and a desire for more.

It is a book you want to own and not a book that you are pleased to see reposing on the dust-covered shelves of a public library. It is a book that answers your questions why and how. It leaves you with the same feeling toward your next distillation problem as the little mouse had who after swallowing two drops of strong liquor, rose on his hind feet and cried loudly, "Now bring on that damn cat!"

There are several typographical errors and a few awkward descriptions that the reviewer has found—mistakes that the average reader can easily rectify for himself. The sub-titles are not as well placed as they might have been, but this does not detract from the value or interest of the book.

A brief outline of the contents can best be expressed in the words of the author:

"In general it has been divided into five parts. The first part deals with fractional distillation from the qualitative standpoint of the phase rule. The second part discusses some of the quantitative aspects from the standpoint of the chemical engineer. Part three discusses the factors involved in the design of distilling equipment. Part four gives a few examples of modern apparatus, while the last portion includes a number of usual reference tables which have been compiled from sources mostly out of print and unavailable except in large libraries."

The first part, dealing with the phase rule, may seem too elementary for some, nevertheless it will be welcomed by others. In a book of this type very little should be taken for granted, otherwise the field for the book will be restricted.

In the second part an attempt is made to derive a few fundamental equations to be used later as a basis for design. Here the reader is led slowly up to the conclusions; he is not jumped from the gas laws to some complicated expression involving calculus. Many of the equations developed are used in actual calculations in order that the reader will have a clearer vision. There are no mysteries in this book; every attempt is made to simplify the ideas and expressions, in order that the reader will not become puzzled and disgusted. Perhaps the subject matter is made a little too simple; some readers might get the impression that the art of distillation is a finished problem. This class of reader never respects anything the theory of which he can grasp. There is another type of reader that will evaluate correctly this theoretical portion of the book. He will see it only as a foundation to build on; it will act as a catalyst for his own ideas. This is one of the valuable features of the book, it opens up new fields of research to the student.

The third part, to many readers, will contain the "meat" of the text. In this part principles of design based on sound theory and long experience are clearly and simply stated. Every chemical engineer in this country will be interested in this part; they have waited a long while for this and they will not be unappreciative.

The fourth part discusses examples of fractional distillation such as the purification of ammonia and alcohol. Principles of design are illustrated by these examples. It is here that one wishes a little more could be said, a few more suggestions offered.

The fifth part, the appendix, contains several tables of data that have been collected and placed in the book because they are useful and are difficult to find and not because they might be useful and are easy to find.

It is hoped that this is a forerunner of more specialized works by other capable men on various fundamental subjects in chemical engineering. If we could have something similar on filtration, on heat transference, on drying, on grinding, etc., our young chemical engineer would rise more rapidly, our executives would cease their grumbling, and the chemical industry would be materially advanced.

It is not often that the reader discovers a refreshing bit of unconscious humor concealed in a highly technical treatise, but when he does his appreciation is sincere. The last lines of Prof. Robinson's text are as follows:

"The waste liquor from the bottom of the column *D* flows through the recuperator *B* and then to the sewer."

A masterpiece of clearness and a very clever ending. O. Henry could have done no better. D. B. KEYES.

MODERN GASWORKS PRACTICE. By *Alwyne Meade.* Second Edition. Rewritten and greatly enlarged. London: Benn Bros., Ltd. 814 pp. 74 illustrations. Price, 55 shillings net.

This second edition represents a 50 per cent increase over the first edition published 5 years ago. This great increase has been necessitated by the many new developments in British gas-engineering practice. The volume is an up-to-date and therefore particularly valuable summary of English gas works equipment and methods.

The practice in English gas works has varied much more in the 5 years past than in the United States. The necessity of war-time fuel economy particularly was a factor necessitating change in quality of gas produced and hence modification in much of the equipment and in methods of operation. The present work emphasizes many of these new practices—for example, devoting a whole chapter to complete gasification of coal and another to cyanogen recovery.

The book deals with production problems only. The author covers these very thoroughly from the retort and generator through to problems of gas holders and storage. Great emphasis is laid upon the mechanical engineering and structural detail. These features are presented very clearly by means of numerous well-selected illustrations.

American gas engineers who plan works or who decide upon matters of technical policy will find much useful material. The work as a whole is rather a text book than a book of reference, and as such it will be appreciated, especially by those who desire to get a broad working knowledge of the engineering tendencies of the day.

R. S. MCBRIDE.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Voting Begins on Chemical Schedule—King Assails Tariff and Monopolies

Voting on the items in the chemical schedule of the tariff bill began on May 2. On that date the real discussion of the chemical items began. Prior to that time the reference to the chemical schedule had been of a general character, although the first item, acetic acid, was the basis of extended discussion. It was brought about by a statement on the part of Senator McCumber to the effect that the action of the committee on that commodity permeated the entire bill. The discussion, however, was more political than technical in its character. When it came to a vote, there was no objection to the adoption of the committee's amendment to the first item in the bill. The next item, acetic anhydride, proved to be a snag as well. In the course of the discussion, Senator Smoot mentioned that the existing embargo applies to all synthetic organic chemicals. This seemed to come as a surprise to Senator Jones of New Mexico and to Senator King of Utah, who thereupon proceeded to denounce the dye and chemical control vigorously. Senator King declared that the majority party drove the measure through Congress, claiming it to be necessary to save the dye industry, and in the interest of the national defense. Under this guise, he said, the embargo was made to apply to all the synthetic organic chemicals, which, he declared, was a "patent fraud upon the people."

King Disregards Dye Investigation Findings

It is very apparent that the evidence before the Shortridge sub-committee has made little impression on Senator King. He is repeating the charges of monopoly in the dye and chemical industry generally in his remarks on the floor of the Senate. In addition, he characterizes the whole tariff bill as absurd, foolish and reactionary. It is sheer madness, he told the Senate, to strike at our foreign trade with such high schedules as are carried by the bill.

"If under the Underwood law," Senator King said, "imports are limited, as they are today, it is hypocrisy to charge that such limited imports menace our industrial and economic security. It is conclusive evidence that the purpose is to cut off all imports, regardless of the effect upon our exports. In the fourth year since the conclusion of the war the balance of trade in favor of our country is relatively greater than before the war. Imports represent an insignificant proportion of the American consumption. The chemical schedule imposes duties upon about 300 different items, covering a wide range of commodities of primary importance. The rates are designed to protect in the sense that they are to be prohibitory, and are intended to operate as an effectual embargo. The rates cannot be warranted from any standpoint of revenue, because the imports in many cases are negligible, not comprising 1 per cent of the domestic production.

Advocates World Market

"As a matter of general policy," continued Senator King, "the endeavor ought to be to permit the industries of the United States the widest possible range for the selection and procurement of the raw materials of the respective trades, particularly in the field of primary chemicals and chemical compounds. There is scarcely a chemical of wide general use and consumption which we do not produce in superabundant quantities. The surplus must find an outlet in the markets of other countries.

"The aim of the American producer is a large production of standardized products. In the pursuit of this purpose he has been willing to remit to the foreign technicians the development and the production of the more refined and complex chemical compounds of small relative consumption, for which a wide world market alone warrants the investment of capital for their composition and production."

After citing instances to show that the increases of duty in the chemical schedule range as high as 700 per cent over the present rate, Senator King declared these rates were made in the interest of companies of very large capital. He then proceeded to list a number of chemical companies and to comment on their financial strength.

Opposition to Potash Schedule

Senator Harris, of Georgia, has introduced an amendment to the tariff bill placing potash on the free list, on the ground that as nearly all potash imports are used in the manufacture of fertilizer the duty proposed in the bill will increase the cost of fertilizer to farmers. The Senate Finance Committee proposed duties for 5 years after enactment of the law, and thereafter the free entry of the product, but the Harris amendment will place the product on the free list immediately.

An amendment by Senator Jones of New Mexico reducing the duty on boric acid from 1½c. to ¾c. a pound was defeated in the Senate by a vote of 26 to 47.

A.C.S. Committee on Society Procedure Appointed to Improve Organization

At the meeting of the Council of the American Chemical Society during the recent sessions at Birmingham, Ala., a motion was passed to the effect that the president of the society be authorized to appoint a committee of seven to consider various suggestions looking toward improvements in Society procedure, such as the method of election of members, the geographical distribution of directors, the status of the advisory committee and the advisability of intersectional meetings.

President Edgar F. Smith has appointed the following committee to cover this matter: A. V. H. Mory, chairman, 634 Hearst Building, Chicago, Ill.; George L. Coyle, L. C. Drefahl, Graham Edgar, H. C. Parmelee, J. N. Swann and R. E. Swain. The committee will be known as the committee on progress in society procedure and its term is to extend to April, 1923.

The committee will welcome suggestions from members on ways and means of improving society procedure along the above-mentioned lines or on other subjects that might fall within its jurisdiction.

Dye Investigation Report in Preparation—Hearings Not Officially Closed

The report which will represent the views of the Shortridge sub-committee which has conducted the investigation of the dye industry is being formulated and will be submitted to the full committee immediately on its completion, which probably will be the latter part of this month. It is practically certain that this report will state that the charges of monopoly in the dye industry have not been substantiated.

Senator Shortridge has made it clear that while there must be an end to the investigation, he does not want to stop taking testimony if there is any one else who cares to be heard. Before the investigation is officially closed, H. E. Howe will appear to explain the chemical exhibit in the committee room.

Substitute for Stanley Patent Bill Proposed by Chemical Engineer

Realizing that compulsory working of patents along the lines suggested in the Stanley bill is too strongly opposed to permit of its becoming a law, Henry Howard, president of the American Institute of Chemical Engineers and chairman of the executive committee of the Manufacturing Chemists' Association, has suggested a substitute. The substitute has been accepted by Senator Stanley.

Mr. Howard's proposal would grant jurisdiction to any United States Circuit Court of Appeals to conduct an investigation upon request of any citizen or firm. Requests for investigation could be made 2 years after the issuance of the patent in cases where the patent is being worked in foreign countries, but not in the United States. The text of the proposed bill is as follows:

> That 2 years after the issuance of any United States patent, or at any time after the expiration of that period, if it is shown that the invention covered by such patent is being worked in a substantial manner in a foreign country, and that the owner thereof has failed to work it in the United States, and has refused or refuses to grant licenses thereunder upon such reasonable terms as would make it practicable to practice the patent in the United States, then on the petition of any reputable American citizen, corporation or partnership, exclusive jurisdiction is hereby granted to any United States Circuit Court of Appeals in whose district or circuit the last known residence of the owner of the patent is located, and in the case of an alien the Court of Appeals of the District of Columbia, to investigate upon proper hearing, all the pertinent facts, and the burden of proof shall be upon the owner of the patent to show that he has been and is using reasonable diligence in bringing about the bona fide working of said patent, either himself or through the aid of licenses in the United States, on a scale sufficient to show a bona fide establishment of the industry therein, and upon failure to make such showing, the court shall order a non-exclusive license granted to the petitioner upon such terms as it shall determine to be equitable. The costs therein to be adjudged to be paid by the party against whom the decree is entered.
>
> After the expiration of 3 years of the granting of a license as herein provided and upon the petition of either party in interest, the court which granted the license shall hear the parties with a view to investigating existing conditions and making such changes in the rate of royalty as in its judgment conditions warrant, the expenses of such proceedings to be charged to the party against whom the decision is made; provided, however, that nothing in this act shall be construed to prevent the parties to such a license from agreeing among themselves as to the royalties to be paid.

Trend of Modern Organic Research Discussed by New York Section

In a delightfully informal and interesting manner, J. F. Norris, professor of organic chemistry at Massachusetts Institute of Technology, addressed the New York Section of the American Chemical Society on May 5 on "The Trend of Modern Organic Research." Prof. Norris remarked that the trend of organic research is shown by the establishment of modern research laboratories by so many companies. It is a significant fact that in a great many cases, professors of organic chemistry have been chosen as directors of these laboratories, showing an appreciation of a need for a complete knowledge of the fundamentals of the subject and of the value of pure scientific research. Another modern indication of this trend is shown by the establishment of research fellowships in various universities by some of the large companies, the recipient being free to choose his subject.

Prof. Norris emphasized the importance of arousing the interest of students in the important developments that grow out of pure science. He declared that the trend of modern research is evidenced by the work of Americans particularly in the field of organic catalysts and accelerators. Developments of increasing industrial significance were discussed such as the hydrogenation of oils, the production of tetra hydro-naphthalene by catalysis, the hydrogenation of drugs such as glucine, strichnine, etc., the production of anthraquinone by catalysis, the preparation of maleic and succinic acid from benzene, anti-knock compounds of tellurium ethyl, etc., production of butyl alcohol and acetone by fermentation, the synthesis of organic compounds with enzymes and organic synthesis through plant life and photochemistry. In petroleum chemistry the trend is to make petroleum the basis of a series of compounds just as benzene is.

In the discussion which followed L. H. Baekeland emphasized the point that the United States spends more money on research than any other country. He deplored the fact that the research chemists were considered as "dead wood" when business depression came and called this a short-sighted policy. R. H. McKee said that he had observed the average time for research work to bear fruit is about 10 years and in view of this fact entered a protest against a 5-year working clause in the patent laws. G. F. Richmond emphasized the demand in industry for men who are well grounded in organic chemistry rather than its specific applications. M. T. Bogert remarked that growing co-operation is evident both on the part of industries and universities in working with an appreciation of the other's viewpoint.

Rochester Meeting, Institute of Metals and American Foundrymen

Following is a list of papers on non-ferrous metallurgy to be presented before the joint meeting of the Institute of Metals Division of the American Institute of Mining and Metallurgical Engineers and the American Foundrymen's Association, to be held in Rochester, N. Y., June 5, 1922.

Institute of Metals Division Papers

"Cracks in Aluminum-Alloy Castings," by Robert J. Anderson.

"The Effect of Impurities on the Oxidation and Swelling of Zinc-Aluminum Alloys," by M. M. Pierce and Mr. Brauer.

"Temperature Problems in Foundry and Melting Room," by John P. Goheen.

"Core-Oven Tests," by F. L. Wolf and A. A. Grubb.

"Occurrence of Blue Constituent in High-Strength Manganese Bronze," by E. B. Dix, Jr.

"Gas Absorption and Oxidation of Non-Ferrous Metals," by Bruno Woyski and John W. Boeck.

"Some Interesting Unsolved Problems of the Foundry," by W. M. Corse.

"Foundry Difficulties," by Adolph Bregman.

"Physical Properties of Cartridge Brass," by C. Upthegrove and W. G. Harbert.

"Effects of Impurities on Electrolytic Zinc," by G. D. Scholl.

"Mechanism of Metallic Oxidation at High Temperatures," by N. B. Pilling and R. E. Bedworth.

"Extreme Sensitiveness of the Action of Reducing Atmospheres Upon Heated Copper," by T. S. Fuller.

"Some Electrical Properties of Nickel and Monel Wires," by F. N. Sobast, M. A. Hunter and A. Jones.

American Foundrymen's Association Papers

"Aluminum and Aluminum-Alloy Melting Furnaces," by R. J. Anderson, Bureau of Mines, Pittsburgh, Pa.

"Melting Aluminum for Rolling Into Sheet," by J. A. Lange, Western Springs, Ill.

"Use of Secondary Aluminum Ingot in Foundry Practice," by W. M. Weil, National Smelting Co., Cleveland, Ohio.

"Technical Control of McCook Field Foundry," by E. H. Dix, Jr., McCook Field, Dayton, Ohio.

"The Use of Secondary Metal in the Brass Foundry," by C. T. Bragg, Michigan Smelting & Refining Co., Detroit, Michigan.

"Porosity of Non-Ferrous Metals," by R. R. Clarke, Pittsburgh, Pa.

"An Investigation of Segregation With a View to Preventing Its Occurrence in Castings Made of High-Lead Bronze," by Prof. R. E. Lee, Allegheny College, Meadville, Pa.

"Two-Part Castings Made in Three-Part Molds," by W. H. Parry, Brooklyn, N. Y.

National Research Council Appoints Division Officers for Coming Year

E. W. Washburn, professor of ceramic chemistry and head of the department of ceramic engineering of the University of Illinois, has been selected as chairman of the Division of Chemistry and Chemical Technology of the National Research Council. His term will begin July 1. He succeeds F. G. Cottrell, who has served as chairman during the current fiscal year. Dr. Washburn will serve as editor-in-chief of the Critical Tables of Physical and Chemical Constants. This work will be the principal project of the division during the coming year. Dr. C. J. West will be associated with the division as its executive secretary and as managing editor of the Tables.

Charles L. Reese was selected as vice-chairman of the division. In addition to the chairman and the vice-chairman, the new executive committee is to consist of Wilder D. Bancroft, R. B. Moore, W. C. Geer and Edgar F. Smith. To the members at large of the division were added the names of W. C. Geer, Lauder W. Jones and Edgar F. Smith. Dr. Smith is to complete the term of Dr. Washburn. Acheson Smith, of Niagara Falls, N. Y., was selected as the representative of the American Electrochemical Society.

Division of Research Extension

M. M. Corse was selected to succeed H. E. Howe as chairman of the Division of Research Extension. W. A. Hamor, assistant director of Mellon Institute, was chosen as vice-chairman of the division. In addition to the chairman and the vice-chairman, the new executive committee of the division will consist of C. E. K. Mees, George C. Stone and F. K. Richtmyer. E. D. Wallen, of Boston, and W. H. Tutwiler, of Philadelphia, were selected to fill vacancies among the members at large of the division.

Officers of Other Divisions

Louis A. Bauer, director of the department of terrestrial magnetism of the Carnegie Institution of Washington, was selected as chairman of the executive committee of the American Geophysical Union. Robert M. Yerkes is continued as chairman of the Research Information Service. William Duane, professor of biophysics of Harvard University, was selected as chairman of the Division of Physical Sciences. Alfred D. Flinn was continued as chairman of the Division of Engineering. Frederick P. Gay was selected as chairman of the Division of Medical Sciences. F. R. Lillie becomes chairman of the Division of Biology and Agriculture.

Fellows Elected

Eleven applicants were elected to Fellowships in physics and chemistry at the meeting of the Division of Physical Sciences of the National Research Council, held in Washington April 23. This is in addition to the thirty-two Fellows who did active work last year and who were reappointed. This work is conducted under the $500,000 appropriation made to the National Research Council by the Rockefeller Foundation to promote fundamental research in physics and chemistry. These Fellowships are awarded students who have had training equivalent to that represented by the Doctor's degree, and enable numerous exceptional students to continue with research work when otherwise they would have to seek gainful employment.

Chemists' Club Continues Employment Bureau

As a result of the action of the Council of the American Chemical Society in declining to take over the employment bureau of the Chemists' Club of New York, the latter will continue to operate the bureau as usual. Employers will find here lists of chemists for work in the plant, laboratory or class room, and unemployed chemists will be able to learn of openings in the profession. A moderate fee is charged to applicants but no charge is made to employers. Prof. Herbert R. Moody is in charge of the bureau at 52 East 41st St., New York City.

Preliminary Program Announced for U. S. Chamber of Commerce Meeting

A preliminary program for the tenth annual meeting of the Chamber of Commerce of the United States to be held in Washington, D. C., May 15 to 18 gives details of the scheduled treatment of the general subject, "European Conditions and Their Effect on American Business." It is predicted that between 4,000 and 5,000 business men will be in attendance.

Monday, May 15, will be devoted to National Council meetings and secretaries' meetings. The latter includes meetings of the National Association of Commercial Organization Secretaries and of the American Trade Association Executives. The former will be addressed by Secretary Hoover, while the trade association men will hear Magnus W. Alexander, managing director, National Industrial Conference Board.

Among the speakers before the general meetings of Tuesday and Wednesday are Joseph H. Defrees, president of the Chamber of Commerce of the United States; Arthur Balfour, vice-president of the Associated Chambers of Commerce of Great Britain; Herbert Hoover, Secretary of Commerce; John R. Howard, president American Farm Bureau Federation; Dwight W. Morrow of J. P. Morgan and Co.; Silas H. Strawn, Montgomery, Ward & Co.; A. C. Bedford, vice-president of the International Chamber of Commerce of the United States, and Albert Thomas, director of International Labour Bureau, Geneva, Switzerland. Each of these speakers will cover a phase of the general topic, so that the symposium should thoroughly cover the economic, financial and industrial aspects of the European situation in respect to the business of America.

The group on foreign commerce, meeting Tuesday and Wednesday afternoons, will hear Frank Taylor, president of the S. S. White Dental Co., on "German Competition" and Julius Klein, chief of the Bureau of Foreign and Domestic Commerce, on "Markets of the Future for Specialties and Staples."

The group on natural resources production is scheduled for a symposium on coal, including mining, labor, selling and transportation problems. A discussion on the extent to which American industries producing raw materials are dependent upon European markets will be led by addresses by C. H. MacDowell, president Armour Fertilizer Works; Sidney J. Jennings, vice-president American Smelting & Refining Co.; J. Leonard Replogle, Empire Steel Co.; Ben B. Woodhead, president Beaumont Lumber Co., and George M. Dexter, president of Dexter & Carpenter, New York City.

Other group meetings include those on civic development, domestic distribution, fabricated production, finance, insurance and transportation and communication.

A.C.S. Petroleum Research Committee Appointed

The Petroleum Section of the American Chemical Society at the recent Birmingham meeting approved the research outlined by Van H. Manning, director of research for the American Petroleum Institute, and also authorized the appointment of a special committee to co-operate with Dr. Manning in the promotion of research on petroleum. W. A. Gruse, of Mellon Institute, who is secretary of the Petroleum Section, has recently announced that the following chemists have been appointed to serve as members of this committee: W. F. Faragher, chairman, Mellon Institute, Pittsburgh, Pa.; R. E. Wilson, Massachusetts Institute of Technology, Cambridge, Mass.; R. P. Anderson, United Natural Gas Co., Oil City, Pa.; N. A. C. Smith, Bureau of Mines, Pittsburgh, Pa.; C. E. Waters, Bureau of Standards, Washington, D. C.; R. R. Matthews, Roxana Petroleum Co., Wood River, Ill., and E. W. Dean, Standard Oil Co., 26 Broadway, New York City.

It will be recalled that in the general meeting at Birmingham, Dr. Manning presented a paper based on the compilation of about seventy problems of the industry which were indicative of the character and scope of research work which he felt should be undertaken by the petroleum chemists.

Chemical Problems of the Felt Hat Industry Outlined Before Milwaukee Section, A.C.S.

Problems of interest to chemists and chemical engineers were emphasized by Alan G. Wikoff, industrial editor of CHEM. & MET., in discussing the felt hat industry before the Milwaukee Section of the American Chemical Society, April 28.

Fur is almost universally used as raw material for felt hats. Contrary to popular impression, no wool is used except perhaps in some of the cheapest hats. In the preparation of the fur for the felting operation, it is dampened, and brushed with a solution of mercuric nitrate, and the treated skin dried quickly in heated ovens or chambers. This operation, which is essential to the development of satisfactory felting properties in the fibers, offers a most interesting field for chemical investigation. The mercuric nitrate acts upon the scales on the surface of the fur fibers in such a way that they stand out sharply and thus present a much rougher surface for the interlocking process which produces felt. However, mercuric nitrate is a dangerous poison and since it is dried on the fibers its effects are felt not only in the carroting department but in many of the subsequent operations. Indeed, mercurialism in the form of "hatters' shakes" has long been associated with this industry. It would seem that a careful study of the swelling and shrinking action of different reagents on protein material might lead to the discovery of an efficient but less harmful substitute.

While there is scarcely a department which does not offer problems of interest to the chemist and chemical engineer, those in the carroting room, the dye house and the stiffening room are most evident.

"Informashow" Offers Interesting Features for Rochester Meeting of Purchasing Agents

The entire group of buildings of Rochester's famous "Exposition Park" has been engaged for the annual convention and exhibition of purchasing agents in that city in order to house a representative exhibition of products. Among the interesting exhibits will be an immense booth planned by the Eagle-Picher Lead Co., showing a complete plant in miniature, engaged in manufacturing sublimed white lead. It is also expected that one of the leading makers of writing paper will have a paper-making plant in operation with a completely equipped laboratory as an educational feature.

This is the first time in the history of the association that the purchasing agents have invited the selling agents to meet them on common ground at an exhibition in connection with their convention. The occasion promises to be unique, as here the manufacturer and his salesmen may display and demonstrate their products to the largest buyers in the country.

Besides the speakers of national reputation who will address the convention on such subjects as "Commercial Bribery," "Arbitration," "Standardization of Coal Contracts," "State and Municipal Purchasing Methods," etc., the group meetings and technical demonstrations will cover many subjects such as iron and steel, cotton, lumber, wool, paper, etc. These group discussions will be led by experts in the various lines.

Favor Revival of Patent Convention With Germany

After having reviewed the arguments for and against the revival of the patent convention with Germany, the State Department is understood to be inclined to revive the treaty under the authority conferred by the Senate.

The Senate Committee on Patents has reopened its hearings on the working clause bill.

Oil Chemists' Meeting Postponed

Owing to serious flood condition of the Mississippi River, the annual meeting of the American Oil Chemists' Society, which was to have been held at the Grunewald Hotel, New Orleans, on May 8 and 9, has been postponed to June 5 and 6.

Recent Oil Developments in Canada

A syndicate which includes Senator N. Currie of Nova Scotia, W. M. Butler of the Canadian Car Co., M. J. Norcross of the Canadian Steamship Lines, General J. W. Stewart of Vancouver and R. N. Wolvin of the British Empire Steel Corporation has been formed to explore a large area of oil lands in the vicinity of Hay River, Alta. Boring operations for oil and natural gas will be started on an extensive scale during the coming summer.

NEW BOOM IN MANY ISLAND DISTRICT

A heavy flow of wet gas was struck recently in a well that was being sunk by the Medicine Hat Development Co. in the Many Island district, 25 miles northeast of Medicine Hat. The gas was struck at a depth of 1,640 ft., and was so "wet" with gasoline that it had the appearance of steam. The strike has caused such a rush for leases that people stood all night outside the Dominion land office, at Lethbridge, to be among the first to file leases in the morning.

The Canadian Government has recently made some changes in the regulations governing oil and natural gas permits and leases in the Northwest territories. Applications for permits must be accompanied by fees at the rate of 50c. per acre, the rental to be computed on one-half of the area of the location. The time limit on which a permitee must have a drill on the ground located has been extended to 4 years from the previous time limit of 2 years. Rentals for the second, third, fourth and fifth years are placed at $1 per acre yearly, but provision is made for certain refunds according to the amount of boring that has been done on the location.

American Society for Testing Materials Announces Program for Atlantic City Meeting

Advance notices of the twenty-fifth meeting of the American Society for Testing Materials have been issued. It will take place at the Chalfonte-Haddon Hall, Atlantic City, N. J. Aside from committee meetings, the various sessions will be as follows:

Tuesday, June 27. Morning: On Non-Ferrous Metals, Metallography and Corrosion. Afternoon: On Wrought, Cast and Malleable Iron. Evening: Presidential address and entertainment.

Wednesday, June 28. Morning: On Steel. Evening: On Impact Testing.

Thursday, June 29. Morning: On Fatigue of Metals and Methods of Testing. Afternoon: On Coal, Coke, Timber and Shipping Containers. Evening: Simultaneous session on Preservative Coatings, and on Concrete Aggregates, Road Materials and Waterproofing.

Friday, June 30. Morning: Simultaneous sessions on Lime, Gypsum and Ceramics, and on Petroleum Products, Insulating Materials, Textiles and Rubber. Afternoon: Golf and tennis tournaments. Evening: On Cement and Concrete.

Warner-Klipstein Merger Reports Unfounded

Recent rumors and statements in the daily press to the effect that the Warner Chemical Co. interests have taken over the E. C. Klipstein & Sons Co. are entirely without authority and without foundation, according to officials of both companies. The Warner interests never have had nor have they now any financial interest in the E. C. Klipstein & Sons Co., it is stated. There has been no change in the friendly relationship between the companies concerned. The working arrangement between the various companies will continue as heretofore.

Public Conference on Muscle Shoals

The Southern Commercial Congress has arranged for a series of public meetings at Florence and Sheffield, Ala., May 22 to 24 to consider the projects for the disposal of Muscle Shoals. Delegates from all over the country are expected. In view of the decided sentiment through the South in favor of the acceptance of Ford's offer, it is probable that the influence of the conference will be exercised toward that end.

Tacoma Chemical Club Forms Council for Service to Community and Profession

A significant step toward a more widespread appreciation of the chemical engineering profession was taken recently by the Olympic Chemical Club of Tacoma, Wash. At the regular meeting on April 11, the club adopted a charter creating an active body of five members to be known as the Chemical Engineering Council which will co-operate with other civic organizations in the up-building of the community. The personnel of the first Council is made up of the following: T. J. Porro, J. E. Berkheimer, S. A. Huntington, Douglas Stewart, R. E. Chase and W. Stedman, ex-officio member.

The purpose of the Council, as stated in the charter, is to promote the general welfare of the community in matters pertaining to chemistry and also to promote the welfare of the chemical profession. The duties of the Council include aiding in the development of desirable new industries, assisting in the proper development of established industries, educating and protecting the public in matters pertaining to chemistry and raising the professional ethics of professional chemists and chemical engineers. It is emphasized that the Council will not attempt to give free consulting advice or encroach upon the field of qualified experts.

The Council plans to meet once a week and has already begun to carry out its duties in accordance with its charter, giving evidence of filling a real need in the community.

Chemical Expenses of Government Reduced—C.W.S. Shows Savings in Varied Fields

Expenditures of government departments dealing with chemistry have been reduced during the year which closes June 30 next, according to a report of the Budget Bureau of Congress. A saving of $32,000 in expenditures in the Bureau of Chemistry of the Agricultural Department is noted, while larger savings are reported for the Chemical Warfare Service of the army, totaling $224,431, not counting $354,380 saved by abandonment of the branch of the service at Lakehurst and its consolidation at Edgewood, Md. At Edgewood there was in addition a saving of $261,215 by developing more economical operation of the power plant.

In co-operation with the navy in the manufacture of gas masks the Chemical Warfare Service saved the navy $129,960. The Service is co-operating with other government departments by use of its facilities, resulting in savings. This co-operation includes aid to the Treasury in fumigating ships, assistance to the Bureau of Mines in producing gas masks for industrial purposes, extermination of harmful insects for the Agricultural Department, measurement for the Bureau of Standards of the flow of gas in large meters used in the natural gas fields, and destruction of locusts for the Insular Bureau in the Philippines and of rats in the sugar cane fields of Hawaii.

Newly Organized Railroad Will Connect Muscle Shoals With Gulf

The Muscle Shoals, Birmingham & Pensacola R.R., organized in Pensacola and charter for operation of which has been granted in Florida, has formally qualified with the Secretary of State of Alabama to engage in business in that state. The proposed railway will connect Muscle Shoals with the Gulf of Mexico, extending from Pensacola northward to a point near Muscle Shoals, with a branch line between Gateswood Junction and Gateswood in Baldwin County. Within the State of Alabama over 300 miles of main track will be constructed, with sidetracks totaling 29 miles.

The railway company is capitalized at $2,500,000, and under the articles of incorporation filed in Tallahassee, Fla., its indebtedness must not exceed $25,000,000. The officers of the company are John T. Steele, Buffalo, N. Y., president; Hubert C. Mandeville, Elmira, N. Y., vice-president, and Roscoe C. Greenaway, secretary. No announcement has been made as to when construction work on the railroad will be started.

Potash Found in New Area in Texas

The discovery of potash in notable amounts in a new area in Texas is announced by the United States Geological Survey. The new discovery is brought to light through the analysis by the Survey of drill cuttings collected from the Santa Rita No. 1 well, drilled by the Texon Oil & Land Co., in the southwest corner of Reagan County, Texas. Most of the samples contained no potash worth noting, but the sample which, according to the driller's log, was taken from bailings after drilling from 1,150 to 1,165 ft., contained the equivalent of 2.46 per cent of K_2O; that from 1,175 to 1,182 ft., 5.63 per cent; 1,155 to 1,265 ft., 5.65 per cent; 1,265 to 1,275 ft., 2.50 per cent; 1,275 to 1,283 ft., 6.38 per cent; 1,283 to 1,293 ft., 7.88 per cent; 1,293 to 1,300 ft., 4 per cent; 1,310 to 1,316 ft., 2.05 per cent, and 1,316 to 1,325 ft., 8.29 per cent K_2O. This, the richest of the samples, indicates 10.78 per cent of K_2O in the soluble salts when 1 gram of the dry rock is dissolved in 100 c.c. of water.

The well was drilled by standard rig. Accordingly the amount of salt taken in solution by the water used in the process of drilling and bailing is not known. Therefore these cuttings, while significant as disclosing the presence of potash salts in this region, which is 120 miles from the Means No. 1 well in Loving County and 55 miles from the Bryant well in Midland County, where also, according to previous announcements of the Survey, potash deposits are present, do not furnish adequate information as to either the precise thickness of the potash beds or the richness of any considerable thickness of salts penetrated by the drill. Core drilling is needed to furnish definite information.

Wisconsin Plans Colloid Research and Symposium During Summer Semester Under Svedberg

The University of Wisconsin announces that Prof. The Svedberg, of the University of Upsala, will be in residence for the second semester of the scholastic year 1922-23 and the summer session of 1923.

The chief interest of Prof. Svedberg while at the University of Wisconsin will be the organization and direction of research in colloid chemistry. In addition to this work he will also deliver a series of lectures on the general subject and will conduct seminaries for those who are interested in special applications of colloid chemistry.

It is planned to hold a general symposium on colloid chemistry at Madison in June, 1923. Prof. Svedberg will be in charge and papers will be presented and discussed by a number of the leading colloid chemists of America. It is hoped that many who are in the teaching profession and in industrial work may find it possible to attend the symposium and the following 6 weeks of lectures, seminaries and research. The summer session opens June 25, 1923, and closes Aug. 3.

Second Conference on Commercial Engineering Points Out Need of Engineering Training

The second public conference on commercial engineering was held at the Carnegie Institute of Technology, Pittsburgh, Pa., on May 1 and 2, under the direction of the committee on commercial engineering of the United States Bureau of Education. The sessions were featured by a number of addresses by prominent engineers and educators and the discussions were participated in freely by those in attendance.

In a statement embodying the principles which the conference believes to be expressive of proper aims and purposes of educational institutions and industrial organizations, the importance of imparting to engineering students a conception of the breadth of the field was stressed. The desirability of introducing some engineering training in the curricula of schools of commerce and business and of economics and business subjects in engineering schools was emphasized. Better co-operation with the industries in shaping the courses to meet the needs of business for technical executives was recommended.

English Chemists' Exhibition Scheduled for June

Announcement is made of the twenty-third Chemists' Exhibition, to be held at the Central Hall, Westminster, facing Westminster Abbey, London, S.W., on June 19-23, 1922.

The exhibition will consist of a most comprehensive display of drugs, chemicals and allied goods. It is attended each year not only by the pharmacists of Great Britain and overseas dominions, but by a number of representatives of the drug and chemical trades from other countries.

Anyone interested in this field visiting London during the exhibition week will be assured of a hearty welcome.

New Steel Development in South Africa Proposed

A group of capitalists in England and South Africa has sent a mining engineer to thoroughly investigate the report that there are important deposits of first-class iron ore and an abundance of coal in South Africa within reasonable distance of each other that might make it profitable for at least one good steel plant. He is just returning to England and states that his investigations have been eminently successful. Deposits of high-grade ore have been proved of sufficient quantity to carry on the industry for 50 of 60 years, while other sources are expected to be developed practically without limit. It is proposed not only to manufacture iron and steel but also to recover tar, sulphate of ammonia, benzene and other byproducts of coke.

Personal

WILLIAM J. BURGESS has resigned from the Electric Storage Battery Co., Philadelphia, Pa., to accept the position of chemical director of the Pennsylvania Coal Products Co.'s plant at Petrolia, Pa.

THOMAS F. COLE has been elected president of the Seneca Copper Corporation, New York, N. Y., succeeding J. Parke Channing, recently resigned.

F. A. J. FITZGERALD announces that the FitzGerald Laboratories, Inc., has been dissolved. He is continuing his consulting practice at Niagara Falls, N. Y.

LENNART VON FRIESEN, assistant chief engineer of Jernkontoret, the Swedish ironmasters' association, is in the United States for a stay of several months, during which time he hopes to inspect many American metallurgial plants.

C. J. GOODWIN, chemical engineer of London, England, left the end of April for a business tour of Europe. He plans to visit France, Belgium, Switzerland, Austria, Germany and Italy.

W. S. GREENE of Los Angeles is leaving for Mexico, having been engaged as designing engineer by Cía. Minera Mexicana Los Tejones, Yaga, Nayaritt, on the construction of its 250-ton cyanide plant.

Dr. FRANKE HAVENS of the Atlantic Products Co., Philadelphia, Pa., has been elected president of the Philadelphia Chemical Club for the ensuing year. JOHN STUTT, of E. I. du Pont de Nemours & Co., has been elected vice-president; CHARLES A. WAGNER, of the Charles A. Wagner Co., is secretary, and WILLIAM THORN, of Innes, Speiden & Co., is treasurer.

Dr. KUNO B. HEBERLEIN, president of the International Process and Engineering Corporation, New York, is in Europe on an extended business trip.

O. P. HOOD, chief mechanical engineer of the Bureau of Mines, is to spend the summer in Europe investigating recent developments in fuels. He will give special attention to the problems of lignite processing and utilization, in order that the bureau may take account of the latest European developments in planning further work on its special program on lignite.

Prof. J. H. JAMES, head of the department of chemical engineering, Carnegie Technical Institute, and Prof. H. C. BASHIOUM, head of the same department at the University of Pittsburgh, Pa., spoke at the recent meeting of the Pittsburgh Section of the Society for the Promotion of Engineering Education, at Carnegie Tech., on "Chemical Engineering Curricula as They Should Be."

T. A. KLEINFELTER, superintendent at the Tottenville (Staten Island) plant of the Atlantic Terra Cotta Co., resigned May 1, to become general manager at the plant of the J. L. Mott Co., pottery branch, Trenton, N. J. He will be succeeded at the Tottenville works by Frederick Parsons.

Prof. H. R. MOODY of the College of the City of New York has been made director of the department of chemistry in that institution in place of the late Dr. Baskerville.

W. W. ODELL, of the Bureau of Mines fuel division, will spend the summer in North Dakota on a further co-operative agreement between the bureau and Prof. Babcock of the university. It is planned to build another lignite retort for manufacture of lignite char, and the work during the coming summer will deal with the behavior of this new retort and the character of the products which can be made from a low-cost installation. The work is based on the assumption, demonstrated by recent investigations of the bureau, that lignite char can be used direct in certain types of stoves and furnaces without briquetting.

JOHN ORTELL, superintendent of safety at the plant of the Carnegie Steel Co., Pittsburgh, Pa., spoke at the recent annual meeting of the Eastern District of the Portland Cement Association, Allentown, Pa.

Dr. LESTER A. PRATT, who has been in charge of the research laboratory of the Merrimac Chemical Co. for the past 6 years, has been made director of research for the company.

D. A. PRITCHARD, until recently electrochemical superintendent of the United Alkali Co. in England, has been appointed works manager of the Canadian Salt Co., Windsor, Ont., Canada. Mr. Pritchard recently arrived from England and assumed his new duties.

CHARLES L. ROBINSON has become general superintendent of the Simes Leather Co., which has recently taken over the A. H. Walton plant at Bridgton, Me.

HERVEY J. SKINNER, of Skinner, Sherman & Esselen, Inc., sailed for Cuba on April 28 on a trip of inspection of the sugar properties of the United Fruit Co. He will probably be occupied on this work about a month.

Dr. W. R. WHITNEY addressed the Denver Section of the American Chemical Society on May 6, 1922. Members of the American Institute of Electrical Engineers, the Colorado Scientific Society and the Teknik Club were also present.

R. E. ZIMMERMAN, director of the research laboratory of the American Sheet & Tin Plate Co., has been appointed assistant to S. A. Davis, vice-president in charge of operations, succeeding the late Robert Skemp.

Obituary

PHILIPPE AUGUSTE GUYE, professor of theoretical and technical chemistry at the University of Geneva, Switzerland, died on March 27, 1922. The following biographical data are taken from the *Tribune de Geneve*, March 29: Prof. Guye was born in 1862 at Geneva. At the age of about 30 he discovered the process for the manufacture of nitric acid from atmospheric nitrogen and in 1894, in collaboration with his brother Eugene and Gustave Naville, patented the electric furnace now classic and known as the "four Genevois" for the industrial realization of his discovery. In 1896 he became professor of physical chemistry at the University of Geneva and later professor of theoretical and technical chemistry, the chair he occupied at the date of his death. His most important contribution to chemical science is the study on atomic weights. He was the founder and editor of the *Journal de Chimie Physique* and edited also the magazine *Helvetica Chimica Acta*.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Foreign Trade and the Business Cycle

The increase in foreign trade during March is regarded as a particularly significant factor in the movement toward business recovery. Exports, which totaled $332,000,000 in March, represent an increase of 32 per cent over the February figure as against a usual seasonal increase of 2 per cent. Imports in March amounted to $258,000,000, a 19 per cent increase over the preceding month. According to the Harvard Economic Service, this advance, which is well in excess of the average seasonal rise of 11 per cent, "shows that imports have probably 'turned the corner.' When seasonal influences and long-time trend are eliminated, October, 1921, appears as the low point; the trend since that time has been upward and the increase from January to March has been substantial. This movement is significant, since imports move with the business cycle, and their upturn at this time corroborates the evidence from other sources that substantial business improvement is under way."

Imports and Exports of Chemicals

Imports of dutiable chemicals in March, 1922, were valued at $3,389,512. The imports of chemicals on the free list were valued at $5,288,365. The figures for March, 1921, were $2,241,914 for the dutiable chemicals and $8,250,542 for free list chemicals. The figures for February, 1922, are $2,713,180 for dutiable chemicals and $4,044,647 for those on the free list.

The value of imports of coal-tar products during March of this year is $681,388. While this is an increase of $250,000 over February imports, it is more than $800,000 less than the imports of these products in March, 1921.

The imports of gums continue to increase. March imports aggregated 9,807,459 lb. This is 2,500,000 lb. greater than the February imports and more than 5,000,000 lb. greater than the imports of March, 1921. Imports of specific items which show important variations are as follows:

	March, 1921 Lb.	March, 1922 Lb.
Oxalic acid	336,114	
Muriate of ammonia	37,514	485,159
Sulphide of arsenic	376,945	1,254,481
Calcium acetate, etc.	22,020,963	4,325,176
Benzene	151,774	
Synthetic indigo	1,471	16,726
Gum arabic	228,654	1,059,626
Synthetic camphor	43,691	161,550
Copal	1,142,267	2,923,715
Shellac	1,530,668	2,009,148
Chloride of lime	319,214	1,000,634
Nitrate of potash	1,061,620	
Cyanide of soda	158,003	1,642,786

The total value of chemicals exported in March was $5,389,386. This compares with $3,803,768 in February and $4,974,194 in March, 1921. Exports of pigments, paints, and varnishes in March, 1922, were valued at $1,057,347. This is an increase of nearly $300,000 over February and exceeds substantially the rate of exportation in March of 1921. There was a slight increase in the exports of fertilizers and fertilizer materials in March of 1922. The increase amounts to about 15,000 tons as compared with February, but is only 2,000 tons in excess of exports in March of last year. There was a very decided increase in explosives exports. The total in March reached 2,113,796 lb., more than double the rate in February. Comparative figures covering a few of the exports are as follows:

	March, 1921 Lb.	March, 1922 Lb.
Benzene	10,809,450	13,164,479
Sulphuric acid	673,314	1,003,128
Acetate of lime	681,050	2,541,897
Calcium carbide	576,442	1,106,905
Copper sulphate	231,171	915,482
Glycerine	164,765	717,833
Magnesium sulphate		178,958
Soda ash	1,000,013	2,411,745
Caustic soda	1,265,411	18,612,225
Bicarbonate of soda	409,525	1,377,158
Zinc oxide	239,403	535,442

Increased Earnings During First Quarter of 1922

Hercules Powder Co. — The quarterly statement of the Hercules Powder Co. for the 3 months ended March 31, 1922, is very encouraging. This company's gross receipts during the first quarter of the current year were $4,243,-659.17, as compared with $2,828,237.70 during the same period of last year. The net earnings from all sources after deducting expenses incident to manufacture and sale, maintenance and repair, depreciation, taxes, etc., was $375,847.20 in the first quarter of 1922. During the first quarter of 1921 the Hercules company had reported a loss of $62,400.80.

Air Reduction Co.—The gross income of the Air Reduction Co. during the first quarter of 1922 was $1,369,673.57. After subtracting operating expenses of $908,718.58 and interest and payment to reserves of $262,889.77 as well as extraordinary charges to profit and loss of $5,784.94, the net earnings of the Air Reduction Co. on its outstanding stock of 153,110 shares amounted to $192,270.28.

Changes in Freight Rates on Lead Pigments

The Interstate Commerce Commission has decided that the proposed reductions in freight rates on sublimed lead and certain other pigments from central territory to Eastern points are not justifiable. Reduced rates on red lead and litharge were approved, however, effective May 8.

Equipment in the Wood-Distillation Industries

The wood-distillation industries have gone through a number of stages of development in their technology, and this is well reflected in the type of equipment now in use in those industries. The old wasteful charcoal pits were first replaced by brick kilns from which condensable vapors could be recovered. This equipment is still being used, but a great forward step was noted when the use of iron retorts, built in pairs, was inaugurated. A still later improvement followed the introduction of large rectangular ovens, which in many of the larger plants have completely replaced the smaller iron retorts.

The number of retorts, ovens and kilns used by the hardwood distillation industries in 1919 and the steam extraction equipment used in softwood distillation are shown

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	159.77
Last week	158.41
May, 1917	222
May, 1920	279
April, 1918 (high)	286
April, 1921 (low)	140

The continued but gradual rise in the prices of three chemicals of basic importance—viz., caustic soda, caustic potash and soda ash—and the sudden strengthening of the linseed oil market are directly responsible for the unusual increase in this weighted index number.

TABLE I—EQUIPMENT USED IN WOOD-DISTILLATION INDUSTRIES, 1919

(Data from Bureau of the Census)

State	Aggregate Capacity (Cords)	Kind and Capacity of Equipment: Retorts Number	Retorts Total Capacity (Cords)	Ovens Number	Ovens Total Capacity (Cords)	Kilns Number	Kilns Total Capacity (Cords)	Steam Extractors Number	Steam Extractors Total Capacity (Cords)
United States	16,088	824	3,140	243	2,008	167	10,070	132	870
Hardwood distillation	14,684	628	2,676	232	1,938	167	10,070	...	...

Louisiana	57	32	40	...	.....	...	.....	8	17
All other states †	98	50	78	...	.....	...	.....	2	20

* Includes Alabama, Connecticut, Kentucky, Mississippi, Missouri, Tennessee and West Virginia.
† Includes Michigan, Mississippi, North Carolina and Texas.

in Table I, which is adapted from the recent bulletin of the Census Bureau on Forest Products.

The production of these industries during the last census year was as follows:

Hardwood distillation products	Quantity
Crude wood alcohol, gal	*9,103,996
Acetate of lime, lb	168,956,432
Charcoal, bu	46,354,432
Tar, gal	552,124
Tar oils, gal	222,398
Wood creosote, lb	945,605

* Includes a small amount of wood alcohol manufactured from softwoods.

Softwood distillation products	Quantity
Rosin, bbl. (280 lb.)	234,030
Turpentine, gal	1,534,333
Tar, gal	2,125,757
Tar oils, gal	581,042
Charcoal, bu	1,702,103
Wood creosote, lb	207,050

New York Market

NEW YORK, May 8, 1922.

A continued active inquiry for solid caustic soda has kept the chemical market in a moderately firm condition during the past week. It is extremely difficult to book any May shipments of standard brands and June contracts are practically sold up. Prussiates have also shown some notable advances, the sodium salt recording a net advance of ½c. per lb. Consuming inquiries have been quite plentiful for copper sulphate and the market throughout the week has shown a decided firmness, with very little prime stock obtainable. Barium products have maintained their recent strength and the market is in relatively light supply at the present time. Small lots of caustic potash are attracting considerable interest and the market has shown a better tone. The chlorates are meeting with a better demand, especially chlorate of soda. Bichromates are moving rather slowly and without any important price variations. Acetate of soda is also considerably stronger. Citric and tartaric acids continue firm, with the latter showing a fractional change. The general market may be summed up as making slow but steady progress in the face of unceasing labor difficulties, the uncertainties surrounding a readjustment of the tariff schedules and the disturbing influences of the coal strike.

General Chemicals

Acetate of Soda—Recent buying of this chemical has noticeably affected spot supplies and sales were reported up to 5c. per lb. Very little material was available and the market was quoted firm at 5@5¼c. per lb.

Amyl Acetate—Sales are reported on the basis of $2 per gal. and quotations are heard at $2@$2.25, depending on quantity. The movement is irregular with no special feature to trading.

Caustic Potash—Numerous inquires have reached the market for the 88-92 per cent, and quite a number of small-lot orders have been booked. Several leading sellers quote 6@6¼c. per lb. The tendency is for higher prices.

Caustic Soda—Firmer conditions have developed in the export market and higher prices were noted. Offerings for nearby shipments are very scarce, while the demand is extremely active for consuming requirements in South America, Japan, Germany and Italy. Outside brands of caustic were held at $3.75@$3.80 per 100 lb., May-June shipment. Dealers report sales for domestic consumption at 3¾@4c. per lb. Producers quote contracts at 2½c. per lb., basis 60 per cent, carload lots, f.o.b. works. Ground and flake caustic were offered at $3.65 per 100 lb., f.o.b. works, carload quantities.

Chlorate of Potash—Several sales were reported up to 6½c. per lb. for the powdered, while in other directions 6¼c. could still be done. Crystals are rather scarce and as high as 8¼c. per lb. was quoted. Producers continue to quote 8c. per lb. for immediate shipment.

Fusel Oil—Leading sellers quote the crude at $1.30@$1.40 per gal. with some trading reported at the lower figure. Refined is quoted at $2.15@$2.50 per gal., depending on quantity. Demand is moderate.

Sal Soda—Producers are booking business on the basis of $1.20 per 100 lb. in barrels, f.o.b. works. Sales at New York were reported at $1.40 per 100 lb. Kegs are quoted at ¼c. per lb. higher. Demand is not very active.

Coal-Tar Products

The continued strength in phenol has been the feature of the coal-tar market during the past 2 weeks. Spot material toward the end of last week was extremely scarce and the market presented a very firm appearance. Buying conditions in the benzene market continue exceedingly strong, with producers able to quote for future shipment only. Naphthalene is moving quietly with very little change reported. Sales of phthalic anhydride were reported somewhat lower at 35c. per lb. Lower prices were heard for monochlorbenzene, and several sales have gone through as low as 9c. per lb. Producers of salicylic acid reported an advance of 1c. per lb. on both grades. It may be stated in general that business in this market is somewhat irregular and confined mostly to specialties. The tone throughout the list, however, is much steadier than noted a few weeks ago.

Beta Naphthol—First-hand sales of the technical grade are reported at 26c. with the general range around 26@27c. per lb. The demand is moderate, with trading mostly in small lots.

Beta Naphthylamine—The technical grade is reported quiet at $1@$1.05 per lb. The sublimed grade is quoted at $1.50@$1.60 per lb., depending upon seller and quantity.

Cresylic Acid—First-hand sales of the 97-99 per cent are going through at 53@55c. per lb. The 95 per cent dark is moving on the basis of 48c. per gal. The market is reported firm, with a moderate amount of business transacted in small lots.

Phenol—Spot material is quoted by dealers at 13½c. per lb., and it is doubtful if better than this price could be done on any available stocks. The demand is very active, with a pronounced tendency of prices going to higher levels.

The Chicago Market

CHICAGO, Ill., May 4, 1922.

Nothing of interest developed in the industrial chemical market during the past week. Buying is still on a small scale and there is but little evidence of anyone anticipating requirements. Nearly all factors report a fair volume of small business and speculative interests are accumulating stocks of a few commodities. Foreign offers continue to be higher and it is noticeable that the quality is falling off. With these advancing foreign prices it is to be hoped that domestic producers will again be able to operate, but on many items the present selling price is far below the domestic cost of production. The local market as a whole may be characterized as very firm with no one complaining.

General Chemicals

Alkalis showed an increased firmness, with spot stocks more or less depleted. *Solid caustic soda* in small lots was available at $3.80@$4 per 100 lb. and the *ground* at $4.35 @$4.50. *Caustic potash* showed no signs of weakening and only small lots were available at 6¾c., while some houses were asking 7c., basis 88-92 per cent. *Soda ash* was firm at $2.20@$2.30 per 100 lb. for 58 per cent material in cooperage.

Alums were moving in a routine way and lacked quotable change. *Potash alum* was available at 4½@5½c. for the technical lumps and 6@6½c. per lb. for the U.S.P. powder. *Barium* compounds were exceedingly firm in price and very scarce. *Barium chloride* was quoted in small or moderate quantities at $110@$130 per ton. *Copper sulphate* continued to be in a firm position, although one factor was offering small lots at $5.75 per 100 lb., city delivery free. *Furfural* was quoted by first hands at 50c. per lb. for quantities in excess of 100 lb. *White arsenic* moved in a small volume at 7½@8c. per lb. The 7½c. material was reported as nearly all absorbed and the general quotation was on the 8c. basis. *Formaldehyde* was dull and neglected at 10c. per lb. for barrels. This figure could very likely have been shaded with a quantity order. *Glycerine* was somewhat easier and it was possible to produce c.p. material at 16c. per lb., bulk basis.

Bichromate of potash moved slowly in consuming channels at 11¾@13c. per lb. *Soda bichromate*, likewise, moved only in a routine way and was unchanged at 9@9½c. per lb. *Red prussiate of potash* was still unavailable on the spot market and offerings for future delivery were scant. *Yellow prussiate of potash* was scarce and very firm at 32@35c. per lb. *Potash permanganate* was neglected and imported U.S.P. crystals were available at 16c. per lb. *Hyposulphite of soda* moved in a fair volume at $3.95 per 100 lb. for the pea crystals in single barrel lots.

Linseed Oil

Linseed oil was reported to be moving in a good volume. Competition was very keen and it was possible to shade regular quotations a cent or two with a good sized inquiry. The boiled oil was offered today in single barrel lots at $1 per gal. and the raw oil in similar lots at 98c.

Turpentine

A good movement of *turpentine* to the paint trade continued during the week and the market was somewhat firmer. Single barrels were quoted today at $1 per gal., with the usual reductions for larger quantities or drums.

The Iron and Steel Market

PITTSBURGH, May 4, 1922.

On the whole, the volume of turnover in the steel market has decreased farther, but in some lines, notably in merchant bars, demand is approximately as heavy as at any time. A general decrease was to be expected from the strong pace of March and the fore part of April, for the rate of buying then was far in excess of both production and consumption.

The demand now seen in the market is of an insistent character, the buyers desiring early deliveries. In not a few instances delivery premiums are offered of, say, $2 or $3 a ton, but the tonnage involved is small. The condition makes a striking comparison with the condition of only a couple of months ago, when all divergences from regular prices were downward. As usual, it is the mills that were formerly most disposed to cut prices that are now most disposed to demand premiums.

It is plain that the influence of the coal strike, on the whole, is helpful to the steel market, tending to stiffen prices and to stimulate demand. Buyers seem to have no uneasiness that they may overbuy, but are exhibiting much uneasiness lest they may not receive sufficient deliveries. Through realizing that production is unlikely to increase much in the next 2 months if at all, mills are very firm in their price views, firmer than would have been expected at a time when production in the steel industry as a whole is at only about 70 per cent of capacity.

Production Heavy

The rate of steel ingot production is probably between 36,000,000 and 38,000,000 tons a year, or slightly heavier than on April 1. The phenomenal increase in production observed in the first 3 months of the year has been largely arrested, but the present rate is likely to continue. Production in December was at a shade under 20,000,000 tons a year, the rate rising to about 30,000 000 tons on March 1 and to 35,000,000 tons on April 1.

Since April 1 production of pig iron and steel in the immediate Pittsburgh district has decreased a trifle, but has been above the average of March. The Mahoning Valley and the Wheeling district have lost a trifle in production, while the Chicago and some other districts have had sharp gains.

The Carnegie Steel Co. has been operating thirty-two blast furnaces in the past fortnight, against thirty-four on April 1. The company's steel ingot production last week was 75 per cent of capacity, against 71 per cent the preceding week.

The regular market on steel products is as follows: Bars, shapes and plates, 1.50c.; bands, hoops and hot-rolled strips, 2c.; standard steel pipe, 71 per cent basing discount; blue annealed sheets, 2.40c.; black sheets, 3.15c.; galvanized sheets, 4.15c.; tin plate, $4.75; plain wire, 2.25c. On nails there are two prices, the independents holding to $2.50, according to their advance about 3 weeks ago, and the American Steel & Wire Co. adhering to the old price of $2.40, at which price it is carefully selecting its bookings. In occasional instances higher prices than quoted here are being paid, but only on small lots.

Billets and sheet bars are not obtainable at prices commensurate with those ruling on finished products, as the mills are not regular sellers, feeling that their previous commitments together with current sales of finished products will absorb all their possible production. Sheet bars might possibly be picked up at $33, but $35 seems a more probable figure, comparing with $29 in March. Report has it that 1,000 tons of billets have been bought at $32.50 Pittsburgh.

Pig Iron Market

There can scarcely be said to be any regular demand for pig iron, and there is no clearly defined market. Buyers know in general approximately what they would have to pay on forced purchases and are quite unwilling to consider such prices. They will exhaust their stocks before making any commitments, in the hope that meanwhile conditions will ease off. It chances that the strikes in the Connellsville region have affected the operation of merchant furnaces in Pennsylvania and Ohio more than the operation of steel works furnaces. Not many were in blast and some of these have had to bank, the result being that furnaces are not openly quoting prices at all. A guess is that about $24, valley basis, would have to be paid on a forced purchase of bessemer, basic or foundry, which compares with prices ruling April 1 of $19.50 on bessemer, $18 on basic and $19 on foundry, valley basis.

Connellsville coke is offered in a very limited way and there is likewise a very limited demand, on account of high prices. The market is quotable 25c. higher than a week ago, at $6.25 for furnace and $6.75 for foundry coke.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	—	$0 38 – $0 40
Acetone	lb.	$0 08 – $0 09	09¼ – 10
Acid, acetic, 28 per cent	100 lbs.	2 35 – 2 50	2 55 – 3 00
Acetic, 56 per cent	100 lbs.	5 00 – 5 25	5 30 – 5 50
Acetic, glacial, 99½ per cent, carboys, 100 lbs.		9 00 – 9 50	9 75 – 10 00
Boric, crystals	lb.	.11 – .11½	11¾ – .12
Boric, powder	lb.	.11 – .11½	11¾ – 12½
Citric	lb.	—	45½ – 46
Hydrochloric	100 lb.	1 10 – 1 20	1 25 – 1 70
Hydrofluoric, 52 per cent	lb.	.11 – .11½	11 – 12
Lactic, 44 per cent tech	lb.	09½ – .10	10 – 12
Lactic, 22 per cent tech	lb.	.04 – .04½	04½ – 05
Molybdic, c.p.	lb.	3 00 – 3 25	3 30 – 3 75
Muriatic, 20 deg. (see hydrochloric)		—	—
Nitric, 40 deg.	lb.	.06 – .06¼	06¾ – 07
Nitric, 42 deg.	lb.	06½ – 06¾	07 – 07¼
Oxalic, crystals	lb.	.11½ – .12	12½ – 13
Phosphoric, 50 per cent solution	lb.	.08 – .08½	08¾ – 09½
Picric	lb.	.22 – .24	24½ – 30
Pyrogallic, resublimed	lb.	—	1 65 – 1 75
Sulphuric, 60 deg., tank cars	ton	11 00 – 12 00	—
Sulphuric, 60 deg., drums	ton	12 00 – 14 00	—
Sulphuric, 66 deg., tank cars	ton	17 00 – 17 50	—
Sulphuric, 66 deg., drums	ton	20 00 – 20 50	21 00 – 22 00
Sulphuric, 66 deg., carboys	ton	—	—
Sulphuric, fuming, 20 per cent (oleum) tank cars	ton	19 50 – 20 00	—
Sulphuric, fuming, 20 per cent (oleum) drums	ton	22 00 – 22 50	23 00 – 24 00
Sulphuric, fuming, 20 per cent (oleum) carboys	ton	31 00 – 32 00	33 00 – 34 00
Tannic, U. S. P.	lb.	—	60 – 75
Tannic (tech.)	lb.	.40 – .45	46 – 50
Tartaric, imported crystals	lb.	—	.27 – 28
Tartaric acid, imported, powdered	lb.	—	.28 – 30
Tartaric acid, domestic	lb.	—	— 30
Tungstic, per lb. of WO	lb.	—	1 00 – 1 10
Alcohol, ethyl	gal.	—	4 75 – 4 95
Alcohol, methyl (see methanol)		—	—
Alcohol, denatured, 188 proof No. 1	gal.	—	32 – 34
Alcohol, denatured, 188 proof No. 5	gal.	—	32 – 34
Alum, ammonia, lump	lb.	.03½ – 03¾	04 – 04¼
Alum, potash, lump	lb.	.03¾ – 04	04¼ – 05
Alum, chrome lump	lb.	07½ – 08	08¼ – 08½
Aluminum sulphate, commercial	100 lb.	1 50 – 1 65	1 70 – 2 25
Aluminum sulphate, iron free	lb.	.02½ – .02¾	03 – 03½
Aqua ammonia, 26 deg., drums (750 lb.)	lb.	.07½ – .07¾	08 – 08½
Ammonia, anhydrous, cyl. (100-150 lb.)	lb.	.30 – .30½	31 – 33
Ammonium carbonate, powder	lb.	.07 – 07½	08 – 09
Ammonium nitrate	lb.	.06 – .06½	06¾ – 07½
Amylacetate tech	gal.	—	2 00 – 2 25
Arsenic, white, powdered	lb.	.06¼ – 07	07¼ – 07½
Arsenic, red, powdered	lb.	.12 – .12½	12½ – 13
Barium chloride	ton	108.00 – 110 00	111 00 – 115 00
Barium dioxide (peroxide)	lb.	.20 – 21	21½ – 22
Barium nitrate	lb.	.06½ – 07	07½ – 08½
Barium sulphate (precip.) (blanc fixe)	lb.	.03¾ – 04	04¼ – 04½
Blanc fixe, dry	lb.	.04 – 04½	—
Blanc fixe, pulp	ton	45 00 – 55 00	—
Bleaching powder	100 lb.	1 60 – 1 75	1 80 – 2 75
Blue vitriol (see copper sulphate)		—	—
Borax	lb.	.05¼ – 05½	.06 – .06¾
Brimstone (see sulphur, roll)		—	—
Bromine	lb.	27 – 28	28½ – 35
Calcium acetate	100 lbs.	1 75 – 2 00	—
Calcium carbide	lb.	04¼ – 04½	05 – 05½
Calcium chloride, fused, lump	ton	24 00 – 24 50	24 75 – 27 00
Calcium chloride, granulated	lb.	.01½ – 01¾	02 – 02¼
Calcium peroxide	lb.	—	1 40 – 1 50
Calcium phosphate, tribasic	lb.	—	15 – 16
Camphor	lb.	—	79 – 81
Carbon bisulphide	lb.	.06½ – .06¾	.07 – .07½
Carbon tetrachloride, drums	lb.	.09½ – .10	10½ – .12
Carbonyl chloride, (phosgene)	lb.	—	.60 – .75
Caustic potash (see potassium hydroxide)		—	—
Caustic soda (see sodium hydroxide)		—	—
Chalk, precip.—domestic, light	lb.	.04½ – .04¾	—
Chalk, precip.—domestic, heavy	lb.	.03½ – .03¾	—
Chalk, precip.—imported, light	lb.	.04¼ – .05	—
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.05 – .05½	05½ – .06
Chloroform	lb.	—	37 – 40
Cobalt oxide	lb.	—	2 00 – 2 10
Copperas	ton	15 00 – 16 00	16 50 – 30 00
Copper carbonate, green precipitate	lb.	.19 – 20	20¼ – 21
Copper cyanide	lb.	—	58 – 60
Copper sulphate, crystals	100 lb.	5.50 – 5 60	5 65 – 6 15
Cream of tartar	lb.	—	24 – 26
Epsom salt (see magnesium sulphate)		—	—
Ethyl acetate com. 85%	gal.	—	60 – 65
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.	—	90 – 95
Formaldehyde, 40 per cent	lb.	.08½ – .09	09¼ – .10
Fullers earth, f.o.b. mines	net ton	16 00 – 17 60	—
Fullers earth—imported powdered—net	ton	30 00 – 32 00	—
Fusel oil, ref.	gal.	—	2 15 – 2 50
Fusel oil, crude	gal.	—	1 30 – 1 50
Glauber's salt (see sodium sulphate)		—	—
Glycerine, c. p. drums extra	lb.	—	15 – 15½
Iodine, resublimed	lb.	—	4 05 – 4 15
Iron oxide, red	lb.	—	12 – 18
Lead acetate	lb.	—	09⅝ – 12
Lead arsenate, powd.	lb.	.14 – 14½	14¾ – 15½
Lead nitrate	lb.	—	15 – 20
Litharge	lb.	.07½ – .08	.08½ – 08½
Magnesium carbonate, technical	lb.	.07 – .07½	07¼ – .08
Magnesium sulphate, U. S. P.	100 lb.	2 50 – 2 60	2 65 – 2 85
Magnesium sulphate, technical	100 lb.	—	1 00 – 1 80
Methanol, 95%	gal.	—	57 – 58
Methanol, 97%	gal.	—	59 – 60
Nickel salt, double	lb.	—	11 – .11½
Nickel salt, single	lb.	—	11 – .11½
Phosgene (see carbonyl chloride)		—	—
Phosphorus, red	lb.	.45 – .46	47 – .50
Phosphorus, yellow	lb.	—	.30 – .35
Potassium bichromate	lb.	10⅛ – .10¼	.10½ – 13
Potassium bromide, granular	lb.	—	.17 – .20
Potassium carbonate, U. S. P.	lb.	.12 – .12½	.13 – .16
Potassium carbonate, 80–85%	lb.	.05 – .05¼	.05½ – .06
Potassium chlorate, powdered and crystals	lb.	.06½ – .06¾	.07 – .08¼
Potassium cyanide	lb	—	.42 – .45
Potassium hydroxide (caustic potash)	100 lb.	6.25 – 6 40	6 45 – 7.00
Potassium iodide	lb.	—	3.10 – 3.15
Potassium nitrate	lb.	.07⅜ – .07½	.08 – .09
Potassium permanganate	lb.	.15 – .15½	.16 – .22
Potassium prussiate, red	lb.	nominal	nominal
Potassium prussiate, yellow	lb.	28½ – .29	.29¼ – .29½
Rochelle salts (see sodium potas. tartrate)		—	—
Salammoniac, white, granular	lb.	.07 – .07½	.07½ – .08
Salammoniac, gray, granular	lb.	.07¼ – 07½	.07¾ – .08
Salsoda	100 lb.	1.40 – 1.45	1 50 – 1.80
Salt cake (bulk)	ton	18.00 – 20.00	—
Soda ash, light, 58 per cent flat, bags, contract	100 lb.	1.65 – 1.70	2.00 – 2.25
Soda ash, light, 58 per cent flat, bags, resale	100 lb.	1.90 – 2 00	2 10 – 2.50
Soda ash, dense	100 lb.	1.95 – 2.05	2.10 – 2.60
Sodium acetate	lb.	.05 – .05½	.05½ – .06
Sodium bicarbonate	100 lb.	1.80 – 1.90	1.95 – 2.40
Sodium bichromate	lb.	.07½ – .07¾	.08 – .08½
Sodium bisulphate (nitre cake)	ton	4.50 – 4.60	4.65 – 5 50
Sodium bisulphite powdered, U.S.P.	lb.	.04¼ – .04½	.04¾ – .05¼
Sodium chlorate	lb.	.06½ – .07	.07¼ – .07¾
Sodium chloride	long ton	12 00 – 13 00	—
Sodium cyanide	lb.	.22 – .23	.23½ – .25
Sodium fluoride	lb.	.09½ – .10	.10¼ – .10½
Sodium hydroxide (caustic soda) solid, 76 per cent flat, drums, contract	100 lb.	3.35 – 3.50	3.80 – 4.00
Sodium hydroxide (caustic soda) solid, 76% flat, drums, resale	100 lb.	3.80 – 3.85	– 3.90 – 4.15
Sodium hydroxide (caustic soda), ground and flake, contracts	100 lb.	3.85 – 4.00	– 4.30 – 4.50
Sodium hydroxide (caustic soda) ground and flake, resale	100 lb.	4.00 – 4.15	– 4.40 – 4.60
Sodium hyposulphite	lb.	.03 – .03¼	.03½ – .03¾
Sodium nitrite	lb.	.08¾ – .09	.09¼ – .09½
Sodium peroxide, powdered	lb.	.28 – .30	.31 – .35
Sodium phosphate, dibasic	lb.	.03¼ – .04	.04¼ – .04½
Sodium potassium tartrate (Rochelle salts)	lb.	—	.18 – .21
Sodium prussiate, yellow	lb.	.18 – .18¼	.18½ – .18¾
Sodium silicate, solution (40 deg.)	100 lb.	.85 – 1.00	1.05 – 1.25
Sodium silicate, solution (60 deg.)	100 lb.	2.35 – 2.50	2.55 – 2.90
Sodium sulphate, crystals (glaubers salt)	100 lbs.	1.00 – 1.15	1.20 – 1.50
Sodium sulphide, fused, 60-62 per cent (conc.)	lb.	.04 – .04⅝	.04 – .05½
Sodium sulphite, crystals	lb.	.03½ – .03⅝	.03¾ – .04¼
Strontium nitrate, powdered	lb.	.09½ – .10	.10¼ – .12
Sulphur chloride, yellow	lb.	.04½ – .05	.05¼ – .06
Sulphur, crude	ton	18.00 – 20.00	—
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.	—	2.25 – 3.10
Sulphur, roll (brimstone)	100 lb.	—	2.00 – 2.75
Talc—imported	ton	30 00 – 40 00	—
Talc—domestic powdered	ton	18.00 – 25 00	—
Tin bichloride	lb.	.09 – .09¼	.09½ – .10
Tin oxide	lb.	—	.37 – .38
Zinc carbonate	lb.	.14 – .14½	.14¾ – .15½
Zinc chloride, gran.	lb.	.05½ – .06	.06¼ – .06¾
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08¼ – .08¼
Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.16 — .16
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1 30
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb.	.75 — .85
Benzoic acid, U.S.P.	lb.	.65 — .70
Benzoate of soda, U.S.P.	lb.	.55 — .57
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97 %, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00½
Beta-naphthol, sublimed	lb.	.55 — .60
Beta-naphthol, tech	lb.	.26 — .28
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.53 — .55
Cresylic acid, 95-97%, dark, in drums	gal.	.48 — .50
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.65 — .70
Dimethylaniline	lb.	.38 — .40
Dinitrobenzene	lb.	.22 — .25
Dinitroclorbenzene	lb.	.22 — .24
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — 24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .65
H-acid	lb.	.85 — 1.00
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.09 — .11
Monoethylaniline	lb.	1.05 — 1.25
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.08 — .08½
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	2.50 — 2.60
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.70 — .75

Ortho-nitro-toluene	lb.	.12 —	.15
Ortho-tolnidine	lb.	.16 —	.20
Para-amidophenol, base	lb.	1.25 —	1.30
Para-amidophenol, HCl	lb.	1.30 —	1.35
Para-dichlorbenzene	lb.	.14 —	.16
Paranitroaniline	lb.	.75 —	.77
Para-nitrotoluene	lb.	.60 —	.70
Para-phenylenediamine	lb.	1.50 —	1.55
Para-toluidine	lb.	1.05 —	1.15
Phthalic anhydride	lb.	.35 —	.38
Phenol, U. S. P., drums	lb.	.13½ —	.15
Pyridine	gal.	1.75 —	2.75
Resorcinol, technical	lb.	1.30 —	1.35
Resorcinol, pure	lb.	1.75 —	1.80
Salicylic acid, tech., in bbls	lb.	.25 —	.25½
Salicylic acid, U. S. P	lb.	.26 —	.26½
Solvent naphtha, water-white, in drums, 100 gal	gal.	.25 —	.28
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.10 —	.12
Sulphanilic acid, crude	lb.	.24 —	.26
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	.28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	.33 —	.35
Xylene, commercial, in tank cars	gal.	.30 —	....

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl	280 lb.	$5.15 —	$5.20
Rosin E-I	280 lb.	5.25 —	5.30
Rosin K-N	280 lb.	5.35 —	6.50
Rosin W. G.-W. W	280 lb.	7.00 —	7.25
Wood rosin, bbl	280 lb.	6.25 —	....
Spirits of turpentine	gal.	86 —	86½
Wood turpentine, steam dist	gal.	.85 —	....
Wood turpentine, dest. dist	gal.	.70 —	.70
Pine tar pitch, bbl	200 lb.	..... —	6.00
Tar, kiln burned, bbl. (500 lb.)	bbl.	..... —	10.00
Retort tar, bbl	500 lb.	—	9.00
Rosin oil, first run	gal.	.37 —	....
Rosin oil, second run	gal.	.39 —	....
Rosin oil, third run	gal.	.46 —	....
Pine oil, steam dist., sp.gr., 0.930-0.940	gal.		1.90
Pine oil, pure, dest. dist	gal.		1.50
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.		.46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla	gal.		.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.		.75
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.		.35
Turpentine, crude, sp. gr., 0.900-0.970	gal.		1.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.		.35
Pinewood creosote, ref	gal.		.52

Fertilizers

Prices remain quotably unchanged

Crude Rubber

Para—Upriver fine	lb.	$0.19 —	.19¼
Upriver coarse	lb.	.13¾ —	.14
Upriver caucho ball	lb.	.14 —	.14¼
Plantation—First latex crepe	lb.	.16½ —	.16¾
Ribbed smoked sheets	lb.	.16½ —	.16¾
Brown crepe, thin, clean	lb.	.14 —	....
Amber crepe No. 1	lb.	.16 —	....

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.10¼ —	$0.10½
Castor oil, AA, in bbls	lb.	.11½ —	.12
China wood oil, in bbls	lb.	.14 —	.14½
Coconut oil, Ceylon grade, in bbls	lb.	.08¾ —	.09
Coconut oil, Cochin grade, in bbls	lb.	.09½ —	.09½
Corn oil, crude, in bbls	lb.	.11½ —	.11¼
Cottonseed oil, crude (f. o. b. mill)	lb.	.09¾ —	.10
Cottonseed oil, summer yellow	lb.	.12 —	.12¼
Cottonseed oil, winter yellow	lb.	.13¼ —	.13
Linseed oil, raw, car lots (domestic)	gal.	.90 —	.91
Linseed oil, raw, tank cars (domestic)	gal.	.86 —	.87
Linseed oil, in 5-bbl lots (domestic)	gal.	.93 —	.94
Olive oil, denatured	gal.	1.15 —	1.17
Palm, Lagos	lb.	.07¼ —	.07½
Palm, Niger	lb.	.06¼ —	.06½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.09¼ —	.10
Peanut oil, refined, in bbls	lb.	.12½ —	.13
Rapeseed oil, refined in bbls	gal.	.83 —	.84
Rapeseed oil, blown, in bbls	gal.	.86 —	.87
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.11¼ —	....
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.09¾ —	....

FISH

Light pressed menhaden	gal.	$0 54 —	....
Yellow bleached menhaden	gal.	57 —	....
White bleached menhaden	gal.	.56 —	....
Blown menhaden	gal.	.61 —	....

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Asbestos, crude No. 1, f.o.b., Quebec, Canada	short ton	$750 00	$900.00
Asbestos, shingle stock, f.o.b., Quebec, Canada	short ton	60 00	—110 00

Financial, Construction and Manufacturers' News

Construction and Operation

California

SANTA BARBARA—The City Council is planning for extensions and improvements in the water system, including filtration apparatus, etc., estimated to cost about $240,000. Fred L. Johnston is city manager.

Connecticut

NEWFIELD—The Tuttle Brick Co., Middletown, Conn., has acquired the brick-manufacturing plant of James C. Lincoln at Newfield, including about 75 acres of adjoining property, for a consideration said to be $60,000. The new owner will operate the plant, and plans for a number of extensions and improvements.

Delaware

SMYRNA—Extensions and improvements will be made to the plant and system of the Smyrna Gas Co., recently acquired by John V. Postles and associates. A company has been organized to operate the plant.

Georgia

CONCORD—The R. H. Strickland Co. has plans under way for the rebuilding of its fertilizer plant, recently destroyed by fire, with loss approximating $75,000. G. E. Strickland is in charge.

Indiana

HAMMOND—The Jones & Laughlin Steel Co., 3rd Ave., Pittsburgh, Pa., has completed the purchase of property at Hammond, totaling about 1,000 acres of land, for a consideration approximating $750,000. It will be used as a site for a new steel works, estimated to cost in excess of $10,000,000. Plans are under way for the initial structures; no announcement has been made regarding the time of erection.

HAMMOND—Fire, April 25, destroyed a portion of the plant of the Wanner Malleable Iron Co., manufacturer of iron castings and kindred products, with loss estimated at about $80,000, including equipment. It is planned to rebuild at an early date.

Iowa

DES MOINES — The Des Moines Gas Co. is planning for the construction of a new gas plant, with gas holder of about 2,500,000 cu.ft. capacity, and general manufacturing equipment. The estimated cost has not been announced.

Kansas

LEAVENWORTH—The Great Western Mfg. Co., manufacturer of machinery, has preliminary plans under way for the construction of a 2-story and basement addition at 2nd and Choctaw Sts., to be equipped as an enameling plant. W. P. & M. K. Feth, Leavenworth, are architects.

Louisiana

ALEXANDRIA—The Old Dominion Glass Co. has commenced the rebuilding of its plant, recently destroyed by fire. New equipment will be installed.

ALEXANDRIA—The City Council is arranging for a special election to vote bonds for $110,000 for a municipal gas plant and system.

HOUMA—John O. Trahan, Houma, is organizing a company to construct and operate a local plant for the manufacture of paper products from sugar cane refuse. A sugar mill will also be erected.

Maine

PHIPPSBURG—The Basin Quarries, Inc., Portland, Me., recently organized, has acquired a local tract of feldspar property, comprising about 100 acres, and plans for the installation of a mining and refining plant, including crushing, grinding, pulverizing and other equipment. Joseph F. Perry, Portland, heads the company.

Maryland

BALTIMORE—The Rennous-Kleinle Division of the Pittsburgh Plate Glass Co., 3221 Frederick Ave., has awarded a contract to the Consolidated Engineering Co., Calvert Bldg., for the erection of its proposed new 4-story and basement plant, 62 x 95 ft., estimated to cost about $50,000. Work will be commenced at once.

CUMBERLAND — Fire, April 26, destroyed the chemical works and laboratory of Alexander Sloan, located in the building at Baltimore and Center Sts., with loss estimated at about $30,000.

EASTON—The Easton Gas Co. is arranging for extensions and improvements in its artificial gas plant and system. The property is operated by Kitzmiller Brothers, Shippensburg, Pa. The work has been ordered by the State Public Service Commission.

Massachusetts

CAMBRIDGE—Fire, April 27, destroyed a section of the plant of the Whittemore Brothers Corp., Albany St., manufacturer of polishes, with loss estimated at about $65,000, with machinery. The bulk of the damage was confined to the mixing department. It is planned to rebuild at an early date.

LYNN—Fire, April 28, destroyed a portion of the plant of the Ryan Ideal Stain & Blacking Co., Washington St., with loss estimated at about $50,000, including equipment.

Michigan

CHEBOYGAN—The Cheboygan Brick & Tile Co. is considering a proposition for the sale of its plant to other interests. It is said that the prospective owners will resume operations at an early date, and plan to make a number of improvements.

Mississippi

LAUREL—The Continental Turpentine & Rosin Co. has preliminary plans under way for the rebuilding of the large portion of its plant destroyed by fire, April 25, with loss estimated at about $100,000, including equipment.

Missouri

IRONTON—The Iron Mountain Co. is planning for the construction of a new iron ore works, including crushing, separating and other departments, estimated to cost about $500,000, including machinery. It is purposed to develop a capacity in excess of 5 cars per day.

POPLAR BLUFF—The Poplar Bluff Rubber Co., recently organized with a capital of $100,000, has plans under way for the construction of a new local plant for the manufacture of inner tubes for automobile tires, and other rubber products. Roy E. Nieman and J. J. Wehlgemuth, Maplewood Postoffice, St. Louis, Mo., head the company.

POPLAR BLUFF—The Iron Exploration Co., a subsidiary of the St. Louis Coke & Chemical Co., Granite City, Ill., is considering the installation of a new crushing and washing plant, with crusher, grinding and other equipment. Plans will be prepared at an early date.

New Jersey

TRENTON—The Ajax Rubber Co., Breunig Ave., manufacturer of automobile tires, etc., has filed plans for the erection of a 1-story addition.

NEWARK — The H. G. Mooney Co., 356 Mulberry St., paper products, has completed plans for the construction of a new 1-story building at Frelinghuysen Ave. and Willow St., to cost about $30,000.

New York

NIAGARA FALLS—The Paper Converting Corp., Royal Ave., is considering the erection of a new 2-story building at its plant, 50 x 80 ft. Plans will be prepared at an early date.

NEW YORK—In connection with the recent acquisition of the West India Oil Refining Co. of Kentucky by the Standard Oil Co. of New Jersey, 26 Broadway, the latter organization will secure an oil refinery at Havana Harbor, Cuba, and has plans under way for extensive operations at this point, with proposed plant improvements.

NORTH TONAWANDA—The Board of Water Commissioners is completing plans and will soon call for bids for the erection of a new filtration plant at the municipal waterworks, to cost about $250,000, with equipment. J. N. Chester, Union Bank Bldg., Pittsburgh, Pa., is engineer.

BATAVIA—The Gypsolite Co., Buffalo, a Delaware incorporation, has filed notice of organization to operate in this vicinity with a capital of $1,000,000. Plans are nearing completion for the construction of a complete gypsum works on local site, comprising crushing, grinding and other departments, to cost about $100,000, including equipment. J. F. H. Haggerty, 66 Bedford Ave., Buffalo, heads the company.

North Carolina

ELKIN—The City Council has completed plans for the construction of a filtration plant in connection with a general waterworks system, and will commence work at an early date. Pegram & Reynolds, Winston-Salem, N. C., are engineers.

MARSHALL—The Town Council has plans under way for extensions in the municipal waterworks to cost about $50,000, including chlorine sterilizer plant. T. A. Cox, 78 Patton Ave., Asheville, N. C., is engineer.

Ohio

YOUNGSTOWN—The Paul J. Kalman Co., 22 West Monroe St., Chicago, Ill., manufacturer of steel bars, etc., will proceed at once with the construction of its new steel-fabricating plant on Cypress St., near Poland St., which has recently been held in temporary abeyance. The plant will cost about $200,000, including equipment. A general contract for completion has been let to the Heller-Murray Co., Furnace St., Youngstown.

Oklahoma

MUSKOGEE—The Oklahoma Producing & Refining Corp. has plans under way for the construction of a new storage and distributing plant to include oil stills, tanks and operating equipment estimated to cost about $250,000 complete. The engineering department of the company is in charge.

TULSA—In connection with a new water development project at Mohawk, near Tulsa, the City Council will install an aerating and sterilizing plant, with complete filtration equipment. The work is estimated to cost in excess of $5,000,000. J. D. Trammell, Fort Worth, Tex., and the Holway Engineering Co., Tulsa, are engineers.

Oregon

PORTLAND—The Columbia Tire Co., 1401 Northwest Bank Bldg., will soon break ground for the construction of a new 2-story plant, to cost about $100,000, with equipment. It will be used for the manufacture of automobile tires and other rubber goods. The Rasmussen Grace Co., 919 Chamber of Commerce Bldg., is engineer in charge. R. A. Wurzburg is head.

Pennsylvania

PHILADELPHIA—H. Swoboda & Son, Inc., 1027 North Bodine St., has completed plans and will soon commence the erection of an addition to its leather-manufacturing plant, to be located at North Bodine and American Sts.

PHILADELPHIA—The Fibre Container Co., Fountain and Nixon Sts., is considering plans for the rebuilding of the portion of its plant, destroyed by fire April 27, with loss reported in excess of $500,000, including equipment.

WAYNESBORO—The Frick Co. will soon call for bids for the construction of a new 1-story foundry, 300 x 600 ft., at its agricultural machinery works, estimated to cost approximately $200,000, with equipment. A. J. Frick is in charge.

CLAIRTON—The Carnegie Steel Co., Pittsburgh, is completing plans and will commence foundation work immediately for the construction of an addition to its local by-product coke plant, estimated to cost close to $20,000,000, including ovens and other equipment. It is planned to double the capacity of the present works.

PITTSBURGH—The Fleischmann Co., 701 Washington St., New York, N. Y., manufacturer of yeast, has tentative plans under consideration for the construction of a new local plant.

Tennessee

MEMPHIS—The City Council plans to call for equipment bids during June for extensions and improvements in the municipal waterworks, including a new filtration plant, estimated to cost in excess of $1,500,000. Fuller & McClintoch, 421 Produce Exchange Bldg., Kansas City, Mo., are engineers.

Texas

FORT WORTH—The Moco Monkey Grip Co., Oklahoma City, Okla., has acquired the local plant of the Texas Motor Car Association for a consideration of about $295,000. The new owner will take immediate possession and plans for the installation of equipment for the manufacture of automobile tires. Employment will be given to about 850 men for initial operations.

Virginia

RICHMOND—The Virginia Carolina Rubber Co., 10 North 19th St., has awarded a contract to E. L. Bass & Brother, 708 Bainbridge St., for the erection of a new 1-story plant, 100 x 125 ft., to cost about $25,000.

Washington

PORT ANGELES—The Union Oil Co. has commenced the erection of its proposed new storage and distributing plant on 2nd St., to have an initial capacity of about 100,000 gal. Three buildings will be constructed, 40 x 50 ft., 26 x 32 ft. and 12 x 15 ft., with steel tanks and other apparatus.

West Virginia

FAIRMONT—The Dixie Co., recently organized, has perfected plans for the construction of a new plant on Speedway St., for oil storage and distribution, to include a complete chemical laboratory. A number of buildings will be erected, with steel tanks and operating equipment. The initial works will cost about $30,000. Walter Smith is general manager.

Wisconsin

MILWAUKEE—The Red Star Yeast & Produce Co., 79-83 Buffalo St., has awarded a contract to the Edward S. Steigerwald Co., 3012 Cherry St., for extensions and improvements in its yeast-manufacturing plant on 27th St. A. N. Graw is president.

Canada

MONTREAL, QUE.—The John Cowan Chemical Co., Ltd., 179 Common St., is planning for the rebuilding of the portion of its plant destroyed by fire, April 26.

New Companies

THE FRASER CHEMICAL CO., Fraser (Macomb County), Mich., has been incorporated with a capital of $25,000, to manufacture washing powders, paint emulsifiers and other chemical products. The incorporators are Ernest Lorenz and Simon Palmateer, Mount Clemens, Mich.; and Charles J. Reindel, Fraser.

THE RILEY-FORD CO., Brooklyn, N. Y., has been incorporated with a capital of $200,000, to manufacture industrial alcohol, chemicals and chemical byproducts. The incorporators are C. Riley, J. E. Ford and W. E. J. Collins. The company is represented by W. E. J. Collins & M. Kamber, 135 Broadway, New York.

THE EAGLE REFINING CO., Houston, Tex., has been incorporated with a capital of $10,000, to manufacture refined petroleum products. The incorporators are O. M., W. E. and Clarence Kendall, all of Dallas.

THE SAVOEI RUBBER MFG. CO., 314 Pond St., Woonstocket, R. I., has been organized to manufacture rubber products. Philias J. Savoei heads the company.

THE PIERPONT PAINT & COLOR CO., Camden, N. J., has been incorporated with a capital of $50,000, to manufacture paints, varnishes, colors, etc. The incorporators are E. C. Young, M. A. Sudlow and W. J. Wix. The company is represented by the Corporation Co., 104 Market St., Camden.

THE TIDEWATER CHEMICAL CO., New York, N. Y., has been incorporated with a capital of $100,000, to manufacture chemicals, paints, dyestuffs, etc. The incorporators are F. H. Twyeffort, J. Moncrief and W. C. Dubois. The company is represented by Fletcher, Brown & Twyeffort, 342 Madison Ave., New York.

THE ARMOR OIL CO., Room 846, 29 South La Salle St., Chicago, Ill., has been incorporated with a capital of $10,000, to manufacture petroleum products. The incorporators are Morton H. Eddy, Oliver C. Heywood and Bernice Gormley.

THE INDUSTRIAL PRODUCTS CORP., Trenton, N. J., has been incorporated with a capital of $125,000, to manufacture brick, tile and kindred products. The incorporators are John P. Fenner, William F. Garton and Fred P. Rearwin, 842 Greenwood Ave., Trenton.

THE UNIVERSAL PRODUCERS CORP., Kansas City, Mo., has been incorporated under Delaware laws with capital of $500,000, to manufacture petroleum products. The incorporators are C. W. Sheppard, Kansas City; F. J. Horton, Iola, Kan.; and L. L. Morgan, Chanute, Mo. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington, Del.

THE D. C. CORP., 1317 Gratiot Ave., Detroit, Mich., has been chartered under state laws to manufacture soap products. The incorporators are Alexander Miller, Theodore M. Browne and Samuel Hoffenberg, 513 Kirby Ave., Detroit.

THE WINNER LABORATORIES, INC., New York, N. Y., has been incorporated with a capital of $50,000, to manufacture chemical products. The incorporators are A. A. and E. F. Smith, and J. Baptiste. The company is represented by Frost, Watson & Sharp, Albany, N. Y.

THE CONVERSION PRODUCTS CORP., New York, N. Y., has been incorporated under Delaware laws with capital of $100,000, to manufacture chemicals, dyes, etc. The incorporators are Lester C. Brulett, John J. Doeley and George W. Study, New York. The company is represented by the United States Corporoation Co., 65 Cedar St., New York.

THE CHARLES S. WILBUR CO., Columbia, S. C., has been chartered under state laws to manufacture paints, varnishes, etc. The incorporators are Charles S. Wilber, E. J. Duffy and George F. Von Kolnitz, all of Columbia.

THE DUNIGAN-PATTON OIL CO., Tulsa, Okla., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are W. A. Dunigan, Tulsa; Paul Patton and C. D. West, Kansas City, Mo.

THE FLORIDA FIBRE CONTAINERS, INC., Leesburg, Fla., has been incorporated with a capital of $150,000, to manufacture fiber products. Edward E. Lacy is president; Gilbert D. Leach, vice-president; and Charles E. Danniel, secretary, all of Leesburg.

THE CENTRAL RUBBER CO., 25 North Franklin St., Chicago, Ill., has been incorporated with a capital of $15,000, to manufacture rubber goods. The incorporators are Robert M. Pierson, Francis J. Loughran and E. E. Schobel.

THE ROY I. L. CARTER OIL CO., Wichita Falls, Tex., has been incorporated under Delaware laws, with a capital of $1,000,000, to manufacture petroleum products. The incorporators are Roy I. L. Carter, Wichita Falls; I. W. Keys and Richard F. Bailey, Mexia, Tex. The company is represented by M. M. Harbordt, Dover, Del.

THE LEON BLOCH BRASS CORP., New York, N. Y., has been incorporated with a capital of $15,000, to manufacture brass and bronze products. The incorporators are L. H. and W. Bloch, and E. C. Cohen, 110 William St.

THE FRANK M. KENNEDY PAINT & COLOR CO., Newark, N. J., has been incorporated with a capital of $50,000, to manufacture paints, varnishes, colors, etc. The incorporators are M. C. and Frank H. Reynolds, and Frank M. Kennedy, 277 Passaic St., Newark.

THE HARRINGTON PETROLEUM CORP., Cairo, Ill., has been incorporated under Delaware laws with a capital of $1,000,000, to manufacture petroleum products. The incorporators are Herbert Harrington, V. C. Clarke and Casper K. Usener. The company is represented by the Delaware Registration Trust Co., 900 Market St., Wilmington.

THE WAYNE BRICK CO., Wayne, W. Va., has been incorporated with a capital of $50,000, to manufacture brick and other burned clay products. The incorporators are C. D. Martin, L. F. Adkins and W. F. Toney, all of Wayne.

THE DUNN-GRENET OIL CO., Pittsburgh, Pa., has been incorporated with a capital of $25,000, to manufacture oil products. V. P. Keefe, Sharpsburg, Pa., is treasurer.

THE ACME POTTERY WORKS, INC., Trenton, N. J., has been incorporated with a capital of $100,000, to manufacture pottery products. The incorporators are Noah W. Boch, A. H. Kennedy and M. K. Hoffman. The company is represented by Frederic R. Brace, 137 East State St., Trenton.

THE PENNZOIL CO., Buffalo, N. Y., has been incorporated with a capital of $1,000,000, to manufacture petroleum products. The incorporators are A. S. Matthews, D. Hyland and R. R. Bearsley. The company is represented by Kent, Cummings & Means, Dun Bldg., Buffalo.

PHILLIP S. MALICKSON, INC., Philadelphia, Pa., has been incorporated with a capital of $100,000 under Delaware laws, to manufacture automobile tires and other rubber goods. The company is represented by the Corporation Guarantee & Trust Co., Land Title Bldg., Philadelphia.

THE TULSA-TENNESSEE OIL CO., Salpulpa, Tenn., has been incorporated with a capital of $75,000, to manufacture petroleum products. The incorporators are George L. Burk, Tulsa; John M. Jones and Grason A. Bailey, Sweetwater, Tenn.

THE BLACK SEAL CHEMICAL CO., Tampa, Fla., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. H. C. McMichael is president; J. L. Moon, vice-president; and H. P. Boyce, secretary, all of Tampa.

THE ATLAS PRODUCING CO., Kansas City, Mo., has been incorporated under Delaware laws, with a capital of $2,500,000, to manufacture petroleum products. The incorporators are Joseph Clover, M. England and R. H. Yates, all of Kansas City. The company is represented by the Corporation Service Co., Wilmington, Del.

FOOSHKILL & HIRSCH, INC., Woodhaven, L. I., has been incorporated with a capital of $25,000, to manufacture ceramic products. The incorporators are W. and S. Hirsch and L. Fooshkill. The company is represented by Slensby & Wolff, Richmond Hill, L. I.

THE DENNETT & PRINCE LEATHER CO., Boston, Mass., has been incorporated with a capital of $25,000, to manufacture leather products. The incorporators are Nathan W. Dennett, Auburndale, Mass.; Fred A. Prince, Sharon, Mass.; and Byron S. Kent, Melrose, Mass.

THE TANNER OIL CO., Lake Charles, La., has been incorporated with a capital of $100,000, to manufacture petroleum products. T. J. Tanner is president, and R. B. Sutherland, vice-president, both of Shreveport, La.; and W. C. Strange, Singer, La.

THE H. A. BLOESER CO., Buffalo, N. Y., has been incorporated with a capital of $5,000, to manufacture turpentine, industrial alcohol and chemical products. The incorporators are H. A. Bloeser, J. R. Hartley and G. E. Keller. The company is represented by Albert F. Geyer, Brisbane Bldg., Buffalo.

THE AMERICAN TEXTILE SOAP CO., Springfield, Mass., has been incorporated with a capital of $100,000, to manufacture soaps and affiliated products. The incorporators are Charles A. Stone, Robert F. Warren, both of Springfield; and Albert F. Alstrom, West Springfield, Mass.

THE WEATHERFORD-BRAZOS REFINING CO., Weatherford, Tex., has been incorporated with a capital of $200,000, to manufacture refined oil products. The incorporators are A. G. Fullerton, V. H. Williams and J. W. Wilson, all of Weatherford.

THE RICHARDS CHEMICAL CO., Glen Olden, Pa., has been incorporated under Delaware laws with capital of $50,000, to manufacture chemicals and chemical byproducts, drugs, etc. The incorporators are Arthur Richards, John H. Yates and J. Lamont Stewart, all of Glen Olden. The company is represented by the Corporation Guarantee & Trust Co., Land Title Bldg., Philadelphia, Pa.

THE HOLSTON FOUNDRY CO., Knoxville, Tenn., has been incorporated with a capital of $10,000, to manufacture iron, steel and other metal castings. The incorporators are H. G. Fowler, C. H. Johnson and C. E. Dawson, all of Knoxville.

THE FRAMINGHAM MFG. CO., Framingham, Mass., has been incorporated with a capital of $125,000, to manufacture iron and other metal castings. The incorporators are: Edward H. Talbot, Sharon, Mass., and Edward A. Hitze, Framingham.

THE TRI-STATES OIL CO., New Boston, Tex., has been incorporated with a capital of $150,000, to manufacture petroleum products. The incorporators are E. B. Guess, G. Roell and Walter Deemer, all of New Boston.

THE ROSENWASSER LEATHER PRODUCTS CO., Brooklyn, N. Y., has been incorporated with a capital of $10,000, to manufacture leather specialties. The incorporators are B. Merker, M. Jones and M. Kanin. The company is represented by C. E. Frankel, 19 West 44th St., New York.

THE STAR OIL CO., Harrisville, W. Va., has been incorporated with a capital of $50,000, to manufacture oil products. The incorporators are B. F. Patten, A. C. Woodford and Edward Robinson, all of Harrisville.

THE CALIFORNIA-PACIFIC OIL CO., Wilmington, Del., has been incorporated under state laws with capital of $5,000,000, to manufacture petroleum products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

Manufacturers' Catalogs

PAUL MAEHLER CO., Chicago, Ill., has issued a new catalog which describes in detail its line of industrial ovens. The construction of Maehler ovens is given, as well as data on ventilation and circulation, assembling or setting up, fuels for industrial ovens, gas-heated ovens, electric heat and its adaptation to Maehler ovens, conveyor and special type ovens, core ovens, potash tanks and boiling cauldrons and oven accessory equipment. The booklet is well illustrated.

THE PAGE STEEL & WIRE CO., Monessen, Pa., has just issued a new handbook describing and illustrating interesting developments in the welding field.

THE AEROIL BURNER CO., INC., Union Hill, N. J., has just received from the press its new bulletin, No. 20, on "Oil-Burning Appliances."

CLEMENT K. QUINN & CO., Duluth, Minn., has issued its 1922 Analyses of Lake Superior Iron Ores.

THE GRINDLE FUEL EQUIPMENT CO., Harvey, Ill., has issued its first general catalog on Grindle powdered fuel equipment, which contains 40 pages of text and illustrations. The advantages of powdered fuel in general is given and the advantages and operation of the Grindle system in particular. Copies will be sent to interested parties on request.

Industrial Developments

RUBBER—The Mason Tire & Rubber Co., Akron, O., has increased its production schedule from 2,500 to 2,800 tires per day, and will soon advance this output to 3,500. The ultimate manufacture will be on a basis of 5,000 tires a day, and arrangements are being perfected for the installation of considerable new machinery for this purpose.

The Seiberling Tire & Rubber Co. is arranging for an immediate increase in production at its New Castle, Pa., and Barberton, O., plants, to a basis of 3,000 tires a day, as against a present schedule of slightly in excess of 2,000 tires.

The Kelly-Springfield Tire Co. is increasing production at its plant at Cumberland, Md.

The Firestone Tire & Rubber Co., Akron, O., is advancing production in its tube-manufacturing department, developing an output of about 3,400 tubes a day.

PAPER—The Parsons Pulp & Lumber Co., Horton, W. Va., has reopened its local pulp and paper mills, and will operate under a day and night shift until further notice.

Paper mills in the Montreal, Que., district are now operating on a basis of about 90 per cent of capacity.

The International Paper Co., New York, N. Y., has placed its new mill at Three Rivers, Que., on an increased operating basis for the manufacture of newsprint.

CERAMIC—The United States Refractories Corp. has resumed operations at its plant at Mount Union, Pa.

The Harbison-Walker Refractories Co., Pittsburgh, Pa., is advancing production at its plants at Mount Union, Pa., and is now operating at both the No. 1 and No. 2 factories.

The National Fireproofing Co., Pittsburgh, Pa., is increasing manufacture at its different plants to handle incoming orders. A number of large contracts have been obtained during the past month for hollow tile, vitrified clay conduit and other fireproofing specialties.

The General Refractories Co. has resumed operations at its plant at Mount Union, Pa., on a 6-day week basis.

CEMENT—The Giant Portland Cement Co. has resumed operations at its Central Mill, Egypt, Pa., following a shut-down since last summer. The company is running at capacity at its Reliance Mill.

Practically all mills in the Lehigh Valley cement district of Pennsylvania are now in operation, including reserve plant units. It is said that production within the next 2 or 3 weeks in this section will be the highest ever recorded.

The Coplay Cement Co. is arranging for the immediate resumption of operations at its Mill B, Coplay, Pa. The Mill C, of the company, with 10 kilns, is now running at capacity.

The Atlas Portland Cement Co., Northampton, Pa., is running full at its local mills, and has announced an increase in wages, effective May 1. The Lawrence Portland Cement Co., in this same section, has also increased the wage scale at its plant.

The International Cement Co., New York, N. Y., has increased production at its different mills, and is now making heavy shipments from the plants.

IRON AND STEEL—The Charcoal Iron Co., Manistique, Mich., is arranging for the resumption of operations at its plants at Boyne City and Newberry, Mich., not later than May 15.

The Brier Hill Steel Co., Youngstown, O., has blown in another blast furnace at its mills. The company is also planning for the early resumption of an additional sheet mill, now said to be impossible through labor shortage.

The Trumbull Steel Co., Warren, O., is now operating 34 hot mills at its plant. The Liberty Steel Co., in the same district, is running 10 hot mills at its works.

The Wheeling Steel Corp. has resumed operations at three mills, located at Yorkville, O.; Creek and Beech Bottom, W. Va., respectively. This brings production up to the highest point for the company within the past 18 months.

The Bethlehem Steel Co. has reopened another finishing mill at its Lebanon, Pa., works, giving employment to about 100 additional men. The unit has been idle for more than a year past.

The American Steel Foundries, Chicago, Ill., is arranging for an immediate increase of 15 per cent in production at its various plants. The company is now running at more than 50 per cent in advance of the output at this time a year ago.

The Rogers-Brown Iron Co., Buffalo, N. Y., has increased production to a capacity basis at its blast furnaces. The company is said to have orders on hand to insure this schedule for the remainder of the year.

The Worth Brothers Steel Co., Marcus Hook, Pa., is increasing production at its mills and adding to the working force. It is planned to adopt a double operating shift at an early date.

The Gulf States Steel Co., Birmingham, Ala., is running full at all of its finishing mills. Two open-hearth furnaces are in service.

The Steel & Tube Co. of America, Chicago, Ill., is running 7 of its 8 blast furnaces at capacity, with orders on hand to insure this basis of output for the remainder of 1922.

Capital Increases, Etc.

THE NEW YORK RUBBER CO., 84 Reade St., New York, N. Y., has filed notice of increase in capital from $500,000 to $800,000.

THE PEERLESS OIL CORP., Richmond, Va., has filed notice of increase in capital from $250,000 to $500,000. A. L. Hawse is secretary.

THE GRAND CORRUGATED PAPER CO., INC., 30 Crosby St., New York, N. Y., has filed notice of increase in capital from $150,000 to $300,000.

THE UNION BAG & PAPER CORP., Woolworth Bldg., New York, N. Y., manufacturer of paper products, with plant at Hudson Falls, N. Y., has disposed of a bond issue of $6,500,000, the proceeds to be used for general operations, financing, etc.

THE WESTON GLASS CO., Weston, W. Va., has filed notice of increase in capital from $50,000 to $75,000.

THE FORT ORANGE PAPER CO., Castleton, N. Y., has filed notice of increase in capital from $200,000 to $500,000.

THE H. C. FRY GLASS CO., Rochester, Pa., is disposing of a bond issue of $600,000, the proceeds to be used for additional working capital, expansion, etc.

THE DECATUR UNION CHEMICAL CO., Decatur, Ill., has filed notice of increase in capital from $150,000 to $180,000.

THE BULLION CHEMICAL CO., Memphis, Tenn., has filed notice of increase in capital from $50,000 to $150,000.

THE PRODUCERS & REFINERS CORP., California Bldg., Denver, Col., operating oil refineries at West Tulsa and Blackwell, Okla., has disposed of a bond issue of $2,000,000, the proceeds to be used for general operations, expansion, etc. F. E. Kistler is chairman of the board.

THE ROGERS-BROWN IRON CO., Buffalo, N. Y., producer of pig iron, coke, ferromanganese, fluorspar, etc., has disposed of a bond issue of $4,000,000, the proceeds to be used for general operations, financing, etc. William A. Rogers is president.

THE CHAPEL LEATHER CO., 308 Prudential Bldg., Newark, N. J., has filed notice of dissolution under state laws.

THE NEW YORK BRASS FOUNDRY CO., 405 Broome St., New York, N. Y., has filed notice of increase in capital from $10,000 to $50,000.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold a joint meeting with the Pacific Division of the association, on the occasion of the annual meeting of the latter, in Salt Lake City June 22 to 24.

AMERICAN ASSOCIATION OF ENGINEERS will hold its eighth annual convention at Salt Lake City, Utah, June 4-6.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Pittsburgh, Pa., Sept. 5 to 9.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 21, 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, Canada, June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its nineteenth annual meeting at Bigwin Inn, Bigwin Island, in the Lake of Bays district, Ontario, Canada, on June 21, 22 and 23.

AMERICAN OIL CHEMISTS' SOCIETY will hold its annual meeting at the Grunewald Hotel, New Orleans, La., June 5 and 6.

AMERICAN PULP AND PAPER MILL SUPERINTENDENTS ASSOCIATION will meet in Kalamazoo, Mich., June 1, 2 and 3.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS is holding its spring meeting at Atlanta, Ga., May 8-11.

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting at the Bureau of Mines auditorium, Pittsburgh, Pa., on May 25 and 26. The International Steel Exposition and Convention of the society will be held in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

ANNUAL SAFETY CONGRESS of the NATIONAL SAFETY COUNCIL will be held in Detroit, Mich., Aug. 28-Sept. 2.

CANADIAN INSTITUTE OF CHEMISTRY and the SOCIETY OF CHEMICAL INDUSTRY will hold their annual meetings in Ottawa May 15-17.

CERAMIC SOCIETY (London) is to have a foreign trip to Sweden and Denmark from May 27 to June 10.

CHAMBER OF COMMERCE OF THE UNITED STATES will hold its tenth annual meeting in Washington, D. C., May 15 to 18.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

NATIONAL ASSOCIATION OF PURCHASING AGENTS EXPOSITION (the "Informashow") will be held in connection with the seventh annual convention of the association at Exposition Park, Rochester, N. Y., May 15-22.

NATIONAL COAL ASSOCIATION will hold its annual meeting at Congress Hall, Chicago, May 24-25.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NATIONAL FERTILIZER ASSOCIATION will hold its twenty-ninth annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 12.

NINTH NATIONAL FOREIGN TRADE CONVENTION will be held at Philadelphia May 10 to 12.

NEW JERSEY CHEMICAL SOCIETY will meet at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: May 12—Société de Chimis Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

A New Trade Association of Chemical Equipment Manufacturers

IN THE organization last week of a trade association by manufacturers of chemical equipment, the chemical industry has now rounded out its quota of such associations. For some time past the producers of heavy and fine chemicals have been organized in the Manufacturing Chemists Association and the Synthetic Organic Chemical Manufacturers Association, and the makers of apparatus have been banded together in the Apparatus Makers Association. The group of four is now completed by the makers of plant equipment, who have just formed the Chemical Equipment Manufacturers Association. With every interest of the chemical industry thus organized, it should be possible through concerted action to accomplish whatever is best for its welfare.

The new association has been launched under most favorable auspices. Trade associations are the order of the day in business. Government encouragement and leadership are offered through the friendly attitude of Mr. HOOVER and the Department of Commerce, which has been reorganized to afford the greatest measure of assistance to business. That there are numerous problems internal to the chemical equipment manufacturing industry is clearly evidenced by the purposes and aims of the new association set forth in its constitution, printed elsewhere in this issue. And if any doubt existed in the minds of the organizers as to probable activities for the association it was dispelled at the first meeting when the subject was thrown open for discussion. Thoughts that apparently had long been slumbering in the minds of those present suddenly found expression in the form of suggested activities for the new organization.

We offer our congratulations to those manufacturers whose foresight has led them to create and foster the Chemical Equipment Manufacturers Association and we urge upon all others the merit of joining and supporting a movement that, in our judgment, must inevitably prove helpful to the industry. There are many problems of common interest to be solved, and doubtless many more will develop as experience is gained. Success in early undertakings will beget confidence in the organization and suggest new lines of activity. The movement has had sound guidance thus far and we confidently predict success if attention is directed primarily to the avowed purposes of the association. The first requisite is a membership representing as nearly as possible 100 per cent of the manufacturers of chemical equipment. The second is the selection of able and energetic officers and committeemen through whom the association will function. To those ends CHEM. & MET. is glad to lend its aid and encouragement and pledge its support.

New Lamps For Old

COMING when naval disarmament did, many fears were expressed that the abandonment of warship construction would prove the last straw to break the back of the deeply depressed metallurgical industry. With steel mills operating at one-quarter capacity or less and important brass works running but one or two shifts a week, to some pessimists it seemed particularly inopportune to shut off one substantial outlet for highly wrought metal and add to the millions of men facing a jobless winter.

However, a little calculation indicated that our warship program consumed an extremely small percentage of the total output of steel and alloys. With the exception of four or five sizable plants engaged in making armor and guns, it makes comparatively little difference to the industry by and large whether we are building warships or not. The proportion of their product going directly to the navy is small indeed—even armor plants are usually single departments of highly integrated steel companies, making almost everything from huge forgings to railroad spikes.

Sober second thought and a wide vision indicated immediately (and events have proved) that the indirect effects of naval disarmament were to be far greater than the direct effects. It is a truism that business is based on credit—that is to say trust—and nothing cuts deeper into the volume of sound trading than suspicion, wars and rumors of war. If naval disarmament increased the sum total of peace on earth by 1 per cent, the direct loss to those industries most vitally concerned has been repaid to them indirectly through their other departments. Other lines of activity have multiplied their profit enormously.

Being of an optimistic turn of mind, we are sure that even the dislocation and scattering of the personnel from the armor and gun plants will quickly redound to the benefit of sound metallurgy. Perhaps this is small comfort to the worker who must hunt up a new job and probably move to a new town, all at considerable loss in money and contentment. But there are few American metallurgical plants whose operations would not eventually profit by adding to their staff even one man who has been exercising for years that meticulous care necessary in the making of fine steels. Granted that the most of the laborers from gun plants are men who merely do as they are told without knowing why they do it, and therefore are not capable of applying their experience to other kinds of product, there are many other men, some with the advantage of college education and some who have acquired their knowledge in the works, men who have studied steel closely for years and have always made a sincere effort to find the cause of failures

in whatever stage of manufacture they occur, so as to avoid them in the future rather than to establish an alibi.

A wise manager does not let such men get away if he can possibly take care of them in any other department. But some managers are not particularly astute, and others may be chained by circumstances. So if one of these technologists of parts, metallurgist, heat treater, melter, smith, whatever he may call himself, is available, and you can obtain his services, do not hesitate to give him a job, for he will prove to be a jewel of great price.

Beginnings of Chemistry in China

IN THE May number of the *Scientific Monthly*, Dr. WILLIAM HENRY ADOLPH gives some interesting notes on the history of chemistry in China. While the Chinese are responsible, he says, for many things long before the European world had developed them, "the tendency has been to consider the hoary annals of Chinese history a convenient dumping ground for disposing of clouded beginnings." We suggest as a secondary reason for the tendency that it is the safer guess. In the early sources of science there were three centers of almost independent development, of which India was the first, China the second and Egypt-Arabia-Europe the third and ours. The Hindus claim responsibility for being the teachers of China, but this is rather a claim than an established fact.

Like the development of chemistry in Europe, the Chinese began with an age of alchemy, which was followed by one of iatrochemistry, but the respective periods in China were much earlier than those of Europe. Alchemy was a Chinese art as early as 1100 B.C. Their iatrochemistry, or inorganic chemicomedical practice, which would more correctly describe it, began very early, but it lasted until the close of the nineteenth century. Two hundred years ago Chinese and Europeans were at about the same milestone of chemical science.

A number of interesting notes are given. For instance, mercuric chloride was used in surgery, although there is no evidence to indicate that the Chinese had any idea of the principle of sepsis. We understand that the people at large are still somewhat unfamiliar with the subject. Practice frequently outran theory, as with us, by many centuries. Gold, silver, copper, iron and tin constituted the "five metals," which were so known for a long time. Indeed the Chinese ideograph for a hardware store is literally translated "Five Metals Shop." Mercury was known as water-silver, and lead, being used only as an adulterant of tin, was not dignified as one of "the metals." This knowledge dates back to the early days of Chinese alchemy. The five metals were regarded as convertible into one another, a belief which grew from the fact that the galenites of China invariably contain all five, in varying proportions. There's a touch of philosophy in this conclusion which is especially interesting in the light of modern research. Discussion of "elements" and "original substance" date back to LOADZE, the great philosopher who flourished about 700 A.D.

Another theory with the odor of prophecy makes all compounds reducible to a single substance which is a gas. The gas may recombine with itself, and assume various forms and groupings. These are secondary elements and one philosopher likens them to vortex rings. They are of two kinds, being either positive or negative in principle. Combination between a negative and a positive may take place, and all the simple, material substances are formed in this way. This theory was put into its final shape in China about the tenth century of our era. With the substitution of hydrogen and H ions and OH ions for various Chinese words used in the text, it comes pretty near to telling what we think we think about matter today.

Alloys were considered as combinations, and much attention was given to the preparation of bronzes. Zinc was compounded with lead and bears the name "secondary lead" in current language. They had a phlogiston theory long before the days of STAHL, and they needed it more than our chemists, because they had scarcely any reagents. Heat was the universal agent used by them in their transformations. White lead is made by what we call the Old Dutch process, but the Dutch got it from the still older Chinese. Sulphates were prepared by oxidation of sulphides; they had no sulphuric acid.

Fevers and Chills In Steel

ABOUT 20 years ago a stock brokerage house got out a prospectus for some new steel venture, inviting the confidence of the public on the ground that the steel industry had lately got into a position of stability and was no longer an uncertain proposition. The steel trade poked some fun at the statement, holding that the industry had been rather a stable affair for years.

Now we can take a longer range view. Much more than 20 years ago the late JAMES M. SWANK had said in one of his annual reviews that the iron and steel industry appeared to be chronically subject to alternations of chill and fever. ANDREW CARNEGIE, who was a great admirer of SWANK, said "prince or pauper," but that expression rather grates on one's nerves these days. Developments of the past 20 months show that the demand upon the steel mills, which is a different thing from the actual ultimate consumption of steel and manufactures of steel, is more subject to chill and fever than was the case 20 years and more ago.

Demand upon the steel mills fluctuates more than does steel production. The steel mills do not stock steel to any extent, simply making it on order. When demand decreases production decreases, but sometimes demand increases more than production, because production reaches a physical limit. Even production, however, has shown unprecedented fluctuations in the past 20 months. In the first 9 months of 1920 the rate of steel ingot production averaged 42,000,000 tons a year. At the middle of the following July the rate was down to about 10,000,000 tons. Then the rate rose to 25,000,000 tons Nov. 1, dropping to less than 18,000,000 tons at the end of the year, while last month has now shown a rate of more than 36,000,000 tons.

The United States Steel Corporation's "unfilled tonnage," which is reported monthly, has shown wide fluctuations, and yet these fluctuations do not exhibit the full fluctuation in demand, for when demand is heavy the corporation is reserved about accepting obligations and does not enter all the tonnage it is offered. The corporation's unfilled tonnage (including unspecified contracts) stood at a high point of 11,118,-

468 tons July 31, 1920, and decreased to 4,141,069 tons at the end of last February, the low point for years. At the end of April it stood at 5,096,917 tons, making an increase of 956,848 tons in 2 months. The shipments during the 2 months were about 1,850,000 tons, so that the bookings were about 2,800,000 tons, a trifle more than the full capacity, which is now reckoned at 53,000 tons (in steel products for sale) per working day. The shipments were at about 65 per cent of capacity in March and 70 per cent in April. Production would have been heavier in the latter month but for the coal strike.

That actual requirements in steel have been increasing since last July is beyond question, but they have not increased either as buying or as production has increased. Last July the country was running largely on stocks of steel and stocks of manufactures of steel. Lately it has been replenishing stocks. Jobbers and manufacturing consumers seem to have but one settled policy, never to keep their stocks uniform, but always to be increasing or decreasing them.

The bituminous coal strike has undoubtedly had much influence in stimulating buyers of steel in the past few months, both when the strike was being talked about as a certainty and when it was an actuality. Strikes have played and still play an important part in steel market history.

Photography as a Tool of Industry

AMONG the familiar tools of science, there is probably none which finds more universal application than the art of photography. In the modern routine of business and industry, there is scarcely an individual who does not depend to some extent upon one of the myriad applications of photography. In fact, such an admirable tool has it become that we are apt to lose sight of the fact that photography is a science in itself, keeping pace with the development of industry through the efforts of its devotees, who are at once scientists and artists.

In order that photography may serve industry most efficiently and blaze the way for progress in the technology of the industries, technical photographers have felt the need of closer co-operation with one another and with the industries that they serve. This sentiment has crystallized in the formation of a new organization, the Technical Photographic and Microscopical Society, details of which are set forth on the news pages of this issue. It is with an appreciation of the importance of industrial photography that we welcome the new society and bespeak for it the co-operation of the chemical and metallurgical industries.

Within the past few years photography has been enlisted to an increased extent in the aid of technology. Industrial establishments are coming to consider the permanent photographic department an invaluable adjunct to the business instead of an added item of overhead, as was once the case. Industrial photography not only has come to stay, but its applications are bound to increase. Witness the field opened by the ultra-rapid cinematograph in motion study or in the study of detailed stresses in physical tests. Witness, too, the development of apparatus for photographing such minute but spectacular physical phenomena as the disintegration of an alpha particle or the pulsations of an alternating current. Metallography has long been indispensable to metallurgical research and photomicrography and macrography are becoming equally important in the pulp and paper and textile industries, in the study of powder, dynamite and other explosives, for the comparison of raw materials in the manufacture of drugs and chemicals, for studying gelatine and other emulsions, for investigations of yeast cultures, bacteria and molds, in studying leather tanning processes, in the technology of rubber, paint and pigments.

A step to correlate the experience and problems of photography in these and other fields should be of mutual benefit to all concerned and should open new uses for an already invaluable aid to industry.

An Innovation in the Teaching of Chemistry

BEGINNING next September, at the College of the City of New York, where Prof. HERBERT R. MOODY succeeds the late Prof. CHARLES BASKERVILLE as director of the department of chemistry, an interesting experiment will be made in presenting the general inorganic course in chemistry. This was formerly given by Dr. BASKERVILLE himself. The innovation will consist in bringing in various members of the staff and occasionally someone from outside the faculty to expound phases of chemistry with which each one is especially familiar and which he has taught successfully. The entire course will be supervised by Professor MOODY, who will address himself more particularly to industrial development within the science and such other features as may call for exposition by him.

This is the series in which the lecture hall is twice filled to capacity for each lecture. The purposes of the experiment are obvious. The students will receive instruction from men who have been tried and approved as teachers of their several subjects. To knit together what is said into a consecutive whole will present its own difficulties, but we have abundant faith in Dr. MOODY'S capacity to do so. It will also bring the leading members of the staff into contact with a large proportion of the student body, which is also desirable. And it will provide a certain stimulus—we may almost say a gentle competition—in the art of exposition, within the faculty.

City College, as it is popularly called, is *sui generis*. It is free to residents of New York. There are very few automobiles or other objects of luxury owned by its students. The courses are intensive, and the students themselves are a very live body of young men. Their attention is remarkably close; they fairly eat up what the lecturer says. It is indeed an unusual experience to appear before them. We shall follow with keen interest the results of the experiment, and, more particularly, its effect on the faculty.

Another innovation which is to be introduced in the fall term is a series of lectures on chemical economics, to be delivered at both the day and the night sessions by Prof. FREDERICK E. BREITHUT, who has returned to the faculty. With the exception of Dr. BERNHARD C. HESSE, it would be difficult to find any one so well equipped as Dr. BREITHUT to explain the sources, the wanderings and the utilization of materials. The advantage of this course to chemists, especially to those engaged in business or technological activities needs no comment, and we predict for Professor BREITHUT a lively attendance, especially at his evening lectures, from the enrollment of graduate chemists.

Readers' Views and Comments

Improved Technology on the Chilean Nitrate Pampa

To the Editor of Chemical & Metallurgical Engineering

SIR:—I was disappointed to read that Paul F. Holstein, an interview with whom appeared in your April 12 issue, although emphasizing the need for improvement in the working of the average nitrate oficina in Chile, failed to indicate, directly or indirectly, the direction that such improvement should take. Many chemical engineers interested in the treatment of Chilean caliche feel that his experience there during many years would add weight to constructive criticism. They would appreciate something more than casual comment on the obvious need for "better recovery, more efficient fuel utilization and improved mining methods . . ."

I suggest that the high cost of extracting the raw material has been due primarily to the expense incurred by selective mining—(1) in hand picking the richer caliche to boost the grade and make possible profitable operations on a small scale, and (2) to avoid the inclusion of slime or borra. Recent developments on one of the most refractory deposits in Chile are tending to disprove the need for this. Large-scale operations are inevitable eventually.

Low recovery of nitrate during beneficiation has been due to the inefficiency of treatment by the Shanks system and a neglect to appreciate the fundamental principles of a logical method of dissolving the nitrate and displacing the nitrate liquor.

High expense in fuel consumption has been aggravated because of a neglect to realize the cheapness and efficiency of solar evaporation in a country where atmospheric conditions are ideal for the purpose.

San Francisco, Cal. A. W. ALLEN.

To the Editor of Chemical & Metallurgical Engineering

SIR:—I think Mr. Allen is entirely correct in his comments on the causes of high cost of extraction of the caliche, low recovery in manufacture and poor fuel utilization. The industry, in my opinion, requires a complete reformation in methods from the extraction of the ore in the pampa to the shipping, every step being susceptible of improvement, some of them in a very great degree. The combined reductions in cost possibly would reduce the cost of nitrate at the plant in many instances by 40 per cent and the cost f.o.b. by several shillings. The past 10 years has seen much, on the whole, unprofitable experimentation with new processes, most of them attempts to apply bits of knowledge snatched from milling practice without any great understanding of the applicability of the methods. The use of filters of various types is an example of one of these unfortunate efforts. While the nitrate man has gained costly knowledge, his enthusiasm has become much dampened as each much-heralded "invention" went the way of its predecessors into the scrap pile. The only definite advance made in many years outside of a better application and control of the old system has been the Allen process, which gets down to fundamentals which, as very usual, means simplification. Filters, screenings, classification, etc., are, in this industry, but medicine for the symptoms instead of for the disease itself.

Specifically I would indicate the following points (among many others) as worthy of study:

1. Co-operation of plants not too widely separated for the centralization of manufacture. The production of a cold solution and its transportation by pipe line to a central plant is not only feasible but has many more or less obvious distinct advantages.

2. The Shanks system has outlived its usefulness mainly through lack of appreciation of the fact that decrease in the percentage of nitrate in the ore being handled is accompanied by an increase in the percentage of insoluble matter and a consequently much greater proportionate retention of liquid by the extracted masses. Indeed old tailing dumps of 15 to 20 per cent nitrate content often indicate a higher percentage recovery of nitrate in those days than a 5 per cent tailings dump does today. The only reason that recovery today is as good as in the early years of the industry must be because of slower operation in leaching. This thought can be carried to its logical conclusion. If it were practicable, a plant consisting of, say, one hundred leaching tanks (cachuchos) and treating ten tank charges (fondadas) per day would give a recovery well over 90 per cent. This has been proved by the writer by experiments on slow operation on full-sized tank charges. It appears therefore that the time factor is a good point for attack, there being several ways by which this factor may be applied in a practical manner. As for leaching in a shorter time with a high recovery, particularly from ores containing much borra, there has been no method tried which appreciates the fundamental principles with the exception of the Allen process.

3. Evaporation of water from leaching tanks is a crime against common sense. As high as 50 per cent of the fuel consumed in some plants is thus driving off water from open boiling tanks. The non-technical manager often appreciates this to the extent only of stopping boiling, and then talks much about saving fuel but very little about recovery. Without entering into the other aspects of the subject, a triple effect evaporator will save one-third of the total fuel.

4. Hand picking of the ore in the pampa is not the only, though the principal, cause of high cost of ore placed at the plant. Several other factors might be mentioned, for instance car-loading, track-shifting, transportation. A penny per quintal here and a penny there is part of the 40 per cent possible reduction in cost previously mentioned. Should the ore be transported, or only the solution transported, to a central plant?

5. Regarding solar evaporation, it may be of interest that experiments conducted by the writer show that a ton of water is evaporated from nitrate solutions from an open exposed area of 3,400 to 3,600 sq.ft. The applicability of this fact has not been sufficiently ap-

preciated, yet it must not be immediately assumed that here is a solution of this point for all conditions; there are other considerations.

I think the most serious need of the industry today is a reconsideration of every step from ore in pampa to sales, without regard to precedent as established by methods outlived, but rejecting, changing and retaining solely by the criterions of simplicity, practicability and accordance with the fundamental facts. Indeed, many changes suggested years ago never really got much beyond conversation, principally because of lack of appreciation of the changing conditions and perhaps, too, of a lack of incentive by competition. Is it not conceivable that, if private producers do not make improvements, it may some day become the business of the Chilean Government, in self-preservation, to step in?

At a later date the writer hopes to go more fully into the above-enumerated and many other points, and though perhaps far from unbiased because of his convictions as to the best means for producing cheaper nitrate, it is believed at least that discussion and criticism will bring out many ideas and eventually establish truths that will serve as a basis for progress.

PAUL FERGUSON HOLSTEIN.

Buffalo Foundry & Machine Co.,

(Sailed for Chile, May 17.)

Mr. Almqvist's Point of View Repudiated

To the Editor of Chemical & Metallurgical Engineering

SIR:—The viewpoint of Harold Almqvist, of Domnarfvet, Sweden, as represented in his letter to you published in your April 5 issue, certainly does not represent, fortunately, the prevailing viewpoint in Sweden.

The majority of the people of Sweden during the war were of the Liberal and Socialistic parties and at no time were pro-German and at no time did they take the point of view your contributor has taken in regard to the European war.

The tone of the letter is unfortunate and the few Swedes to whom I have shown this letter have all expressed themselves as highly regretting Mr. Almqvist's contribution of provincial venom.

San Francisco, Cal. J. W. BECKMAN.

Henry P. Davison—An Appreciation

To the Editor of Chemical & Metallurgical Engineering

SIR:—The name of the late Henry P. Davison, of J. P. Morgan & Co., who died on May 6, is doubtless familiar to most of your readers, although he was distinctly a banker, and as such he became eminent. He had the banking mind, with singular freedom from its faults. He did not think he knew what he did not know. He was, however, a person of such potentiality in affairs and of such remarkable strength that a note on his passing may not be amiss. He was one of the few financial leaders of this country. Our reserve banking system was largely of his making. Immense institutions of today are the children of his imagination and his great organizing ability. During the war his work to relieve suffering was probably unprecedented in the annals of history. And he was always constructive; he would not destroy for profit.

What manner of man was he? There was nothing unusual in his bringing up. His mother died while he was a young child, his father was of a roving disposition, and he grew up with a couple of elderly uncles who owned the village bank in Troy, Pa., where he was born. They sent him to boarding school, but would not send him to college, which was a sore disappointment to him. Later he received no fewer than ten doctorates of law from leading universities and the grade of Major-General from the U. S. War Department. He taught school, became a bank clerk in Bridgeport, Conn., then in the Astor Place Bank in New York, and within a few years he was president of the Liberty Bank at the age of 31.

But how did he do it? We can give only incidental facts about him. He had a very engaging quality of good fellowship. Few men are loved as he was by those who were close to him. He was the best kind of company, with a rich sense of humor, although serious things were not funny to him. He did not worry about his dignity; that took care of itself. He was just a little quicker on the trigger than most other men; a little keener to sense what was going on. When he was a bank teller and a lunatic presented a check for a thousand dollars drawn to the order of Almighty God together with the end of a loaded revolver, he engaged him in such pleasant conversation about the size of the bills he wanted and meeting his convenience in every respect that the lunatic forgot to shoot until he was pinioned from behind. He thought only a little harder, a little more intensely, than other men.

He was not a speculator, and yet, when he knew he was right, there seemed no limit to his courage or his nerve. He recognized talent when he saw it, and thus surrounded himself with men of signal ability. He paid a little above rather than a little less than the market rate for services rendered. But he had also the catalytic quality that develops ability in others which theretofore lay dormant. There was no trickery in this; it was merely a little extra gift of what we call intelligence. Had he been selected as president of Yale, for which post his name was earnestly considered, and had accepted the task and retained his health, he would have been a rare inspiration to the students.

There was no particular quality that stood out as explaining his success in everything except perhaps his likableness and his resolution. At the age of 19 he wanted a post in the First National Bank of New York, but was frightened away by the man at the door. Fourteen years later he entered it as first vice-president. While at Bridgeport a post as cashier of a suburban bank with better pay was offered him, but he refused because he did not want "to get lost in a hole." When he applied for the position of paying teller in the Astor Place Bank he was refused. Three times he visited the vice-president, urging his suit, and the third time he won it. Then the vice-president telegraphed him that strong pressure was brought to bear to give the place to another, and would he accept a junior position at less pay? He replied that he would gladly do so. Three months later he was paying teller. This shows a little longer vision and a little more clearly defined purpose than most young men possess. His other qualities all seemed just a shade or so more developed than those same qualities in other men who are good and competent without being national figures or even great.

What a grand thing it would be for chemistry to add minds and characters of that sort to the practice of the profession! I do not deny that we have them, but we need more of them.

ELLWOOD HENDRICK.

New York City.

Thermal Problems of Petroleum Refining

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your April 26, 1922, issue an article appeared by L. A. Mekler entitled "Thermal Problems of Petroleum Refining." On page 775 equations for coefficients of heat transfer *a* and *b* were given.

While probably Mr. Mekler did not intend to give the impression that the coefficients *a* and *b* respectively would hold for any cold or hot fluid flowing through a pipe, the casual reader might infer that the expressions given for *a* and *b* were *general* equations. The facts are that the value given for *a* represents certain data for *water* flowing inside pipes over a definite range of velocity and temperature, and similarly *b* represents certain data for *air*.

As a result of more recent investigations, equations more accurate than those quoted by Mr. Mekler are available for the flow of both gases and liquids in pipes.

As shown in recent articles, the *general* equations for the heat transfer coefficient between a fluid and the pipe through which it is flowing are quite complex because of their generality and must include corrections for the physical properties of the fluid being handled, such as viscosity, etc. In designing an oil to oil or a vapor to oil heat exchanger or preheater, the use of the coefficients quoted by Mr. Mekler may introduce enormous error; in the case of a direct-fired oil preheater or still, suitable allowance should be made for the transfer of heat by radiation, in addition to that transferred by conduction and convection.

Massachusetts Institute of Technology,
Cambridge, Mass.

Austrian Chemical Industries

FROM OUR SPECIAL CORRESPONDENT

VIENNA, March 22, 1922.

WITH the collapse of the Austro-Hungarian monarchy the new Austria has become a country with a rather weak and undeveloped chemical industry. Entire branches of its former industry have disappeared, not only because the works were located in the territory of some of the new succeeding states, such as Czechoslovakia, but also because raw material is not at all available or is present in insufficient quantities within the Austrian borders. Such, for instance, is the case with both the mineral-oil and the beet-sugar industries. Attempts have been made to increase the growth of beets in Austria, but so far only very modest progress can be reported. The harvest of 1921, because of unusually unfavorable climatic conditions, did not even reach the quantity produced in 1920.

CHINA AND GLASS INDUSTRY

A new deposit of kaolin has recently been discovered in upper Austria and there has resulted a considerable expansion of the ceramic industry. A new chinaware factory will soon be erected near Wels. A factory for the manufacture of plate glass, established in 1920, is working at Attnang (upper Austria), but up to the present time has been able to furnish only a small part of the plate glass needed in Austria. The purpose of these efforts is, of course, to render Austria as far as possible independent of Czechoslovakia, where nearly all of the glass factories of the former monarchy had been concentrated. It is also reported that another company, founded in 1921, has taken up the manufacture of glassware in Stockerau, near Vienna.

PHARMACEUTICAL CHEMICALS

Industrial activity along pharmaceutical lines has had an unusual development since the breakdown of the monarchy. Existing establishments have been enlarged and a goodly number of new plants have been erected, some of which, to be sure, are still in the early stages of production. A factory producing salicylic acid in Kufstein, belonging to the firm Suchy-Werke, has already taken up work and the same firm is also manufacturing ichthyol products from a fossilliferous oil obtained from a seam of oil shale lately discovered in Tirol.

INORGANIC CHEMICAL INDUSTRY

The production of sulphuric acid during the war had been increased to a considerable extent. The annual productive capacity at the end of the war is compared with that of 1913 in the following table:

	1913		End of War	
	Sulphuric Acid, 92 to 98 Per Cent, Tons	Oleum, 20 Per Cent, Tons	Sulphuric Acid 92 to 98 Per Cent, Tons	Oleum, 20 Per Cent, Tons
Austria	60,000	3,900	80,400	62,700
Hungary	16,800	800	61,200	27,700
Total	77,500	4,700	141,600	90,400

The actual consumption during 1921 amounted to 53,000 tons of domestic production and 22,000 tons of acid imported from Germany, making a total of 75,000 tons. The total productive capacity after the war calculated in terms of 92 per cent sulphuric acid amounted to 236,000 tons, or something like three times pre-war requirements. The breakdown of the monarchy, however, has left Austria with only two oleum factories and one other important establishment producing other strengths of sulphuric acid. The production of pyrites had also been increased to 25,000 tons a month during the war, principally by more intensive operations of existing works and the resumption of production at various abandoned mines. In the new Austria pyrites is now mined at only a few places and in relatively small quantities, so that there is practically no domestic raw material for manufacturing sulphuric acid. Recently, however, it has been announced that the newly organized Permanganat-Aktiengesellschaft of Linz, which since 1921 has been producing potassium permanganate by an electrochemical process, is going to erect a new factory for sulphuric acid production. The same company is also erecting some new plants for wood distillation, since there is an entire absence of such an industry at the present time in Austria proper.

The situation as far as the manufacture of caustic soda is concerned is much more favorable. Austria has, it is true, lost nearly all of the establishments for the manufacture of this article, but the raw material is available in abundance from the brine of the Salzkammergut. Consequently the industry is preparing to manufacture caustic soda on a large scale. The Bosnische Elektrizitats-Gesellschaft has enlarged its plant at Klagenfurt until it now has several times its former capacity. A new company, Elektro-chemische Werke of Aussee, is erecting a hydro-electric plant which will produce caustic soda electrolytically. The previously mentioned permanganate company at Linz also intends to produce caustic soda from brine in this manner. The utilization of considerable quantities of

chlorine, however, presents a very difficult problem. Only a small quantity can be used for manufacturing bleaching powder. It is hoped that there will be a commercial development for using chlorine in chlorinating methane, since natural gas is available at Wels, which is very near the salt mines. The opinion as to the quantity of gas to be obtained from these sources is, however, widely different.

The works of the former state gunpowder factory at Blumau, which during the war had been enlarged to enormous dimensions, have already been transformed and adapted for peace-time production. Their newly organized chemical company produces nitric acid, hydrochloric acid, sodium sulphate, and in addition a number of organic chemical products. Furthermore a fertilizer factory has been installed there and the melinite factory of Blumau has been altered and adapted for the manufacture of coal-tar products, such, for example, as aniline and certain basic colors. Only the oleum plant was not changed. A second large gunpowder factory had been built during the war by the Skodawerke-Wetzler Aktiengesellschaft near Tulln, but these works, with a power plant of 9,000 hp., and an estimated capacity for producing 400 tons of gunpowder per month, have not yet engaged in any extensive peace-time pursuits. An exception, however, is in the case of copper sulphate and chrome alum, now being made there.

Italian Chemical Industries

From Our Special Correspondent

Genoa, Italy, April 6, 1922.

During the past 5 weeks there has been some recovery in the status of the Italian chemical industries. One reason has been the larger supply of electric current available due to an increase in the utilization of water power; another has been a further reduction in the price of coal and of certain imported raw materials. A general strike in all of the Italian ports recently brought imports and exports practically down to zero, crowding the harbors with ships loaded with all kinds of merchandise. In the port of Genoa alone there were at the end of March as many as twenty-seven ships loaded with coal awaiting discharge, and many others have since arrived. The industries that suffered most through this situation were the fertilizer manufacturers, the sulphur-mining industry and the metallurgical industry.

Fertilizers

After a series of discussions between the owners of the principal Italian fertilizer plants and their workers, an agreement has finally been reached which will keep alive the wage contracts effected last November. There are other factors, however, which are seriously affecting this industry. The situation in the phosphate market has completely changed owing to the continued fluctuations in foreign exchange and the increase in the cost of transporting phosphate rock from the mines to the sea in the principal countries of origin. During 1921 conditions in the phosphate industry were practically normal. The output of superphosphate was 501,975 tons, as compared with 496,575 tons in 1920. The maximum productive capacity of Italian plants for producing superphosphate is probably in the neighborhood of 750,000 tons. Consumption in Italy during 1921 was about 850,000 tons, although in 1913 it had reached 1,070,000 tons.

During the war practically all of the supplies of nitrate of soda were used for the production of explosives. Sulphate of ammonia, produced as a byproduct in the manufacture of illuminating gas, was produced in a quantity corresponding to only about one-half of the pre-war output. Likewise the importation was enormously reduced. During 1913 there was a consumption of about 100,000 tons of nitrogenous fertilizer; in 1918 this had fallen to 50,000 tons and in 1919 it remained at approximately this amount. Some little increase was noted in 1920, and there was further betterment in 1921. During this latter year the consumption of nitrate of soda was 32,000 tons, against an average of 55,000 tons before the war; that of sulphate of ammonia was 20,000 tons (of which only about one-half is of domestic origin), against an average consumption of 35,000 tons in 1913. The consumption of ammonium nitrate was about 12,500 tons, that of cyanamide was 16,000 tons in 1921 and 24,000 tons in 1920. Italy consumed only about 8,000 tons of crude potash salts during 1920, as compared with 28,000 prior to the war. The average consumption of potash in Italy at that time was 0.8 of a kilo per hectare of cultivated ground, while in France the average was 3.2 kilos, in Belgium 20 kilos and in Germany 63 kilos.

Sulphur and Blue Vitriol

A meeting was held in Rome about the middle of last month for the purpose of demanding the immediate intervention of the government in settling the crisis existing in the Sicilian sulphur industry. It has since been reported that a large Italian bank would offer financial backing to one of the most important mines, and it is hoped that this will result in speedy recovery and consequent re-employment of the miners.

The sulphur refineries of Cesena, Bellisio and Pesaro have been working regularly with satisfactory results and continue to produce products of good quality which find sale in Italy and abroad. The refinery of Murano was closed and its work taken up by the refineries at Bagnoli, Borgo Panigale, Pozzolo, Reggio and Rifredi. The Societa Unione Raffinerie Siciliane, as a consequence of the high prices arranged by the sulphur consortium for its raw material, has had to reduce its activity considerably.

The consumption of copper sulphate was unusually good in 1921 and the establishments at Vicenza, Casale, Rifredi and Bagnoli were able to take care of a considerable part of the supply. A new plant is under construction at Reggio Emilia and it is believed that a plant in this locality will facilitate the distribution of the product and also reduce expenses of transportation. Blue vitriol will also be produced in the works at Piano d'Orte and in other chemical plants of that vicinity. The total production of copper sulphate at present is about 1,000,000 tons per year, whereas the national requirements are probably only about 750,000 tons.

Pharmaceutical Products

On March 4 the special committee which is assisting the Ministry of War in the sale of those pharmaceutical chemicals obtained from Germany on account of war reparations established a sales organization for these products with the Farmacia Centrale Militare of Turin. Certain limitations have been set on these sales with a view to protecting the interests of the Italian industry producing pharmaceutical products. It is reported that the German goods are in very good condition and nearly all are in the original package bearing the name of the original producer.

The Business Side of Chemical Manufacturing

In This Article, the Second in the Series, the Marketing Function Is Analyzed, the Necessary Steps Are Outlined and a Detailed Consideration of the Advertising Department Is Undertaken

By CHARLES WADSWORTH, 3d

THE marketing function in any organization includes a number of departments. The scope of these departments varies tremendously with the type of organization and with the men in it. If, for example, we were to describe accurately the functions of the sales department in a given organization today and if tomorrow a new sales manager were appointed, we would have to rewrite our description. The old description would not fit the new department. Let us take a mythical example. Old J. P. Smith, head of the sales department, had been with the company 30 years. He was a Tartar and people never intentionally aroused J. P.'s wrath. Fulton, head of advertising, was the only one who dared to argue with him, but "J. P." had the final say on all marketing policy. "J. P." died, and Sprague, metropolitan district sales manager, took over the work, but Fulton dominated sales policy from that time on. So you see we would first have said the advertising manager formulated all the plans for campaigns, but they were always revised and approved by the sales manager. After "J. P.'s" death we would have to say the advertising manager had entire charge of the planning of the marketing campaigns and the co-operation of the sales department was tacitly assumed. With the possibility of such variations in mind, let us examine the various component departments co-operating in the marketing function of an organization. The following steps are undertaken in the order named and the work is accomplished by the department or group listed on the same line.

1. Locate the market.	Sales research or engineering.
2. Interest it in the product.	Advertising.
3. Classify prospects.	Credit.
4. Consummate sales.	Sales.
5. Deliver the product.	Traffic.
6. Keep customer satisfied.	Trouble dept., or sales source.
7. Collect the bills.	Collection (or credit).

There are a great many more incidental steps necessary which will be taken up under the detailed consideration of the departments, but those steps just mentioned summarize the functions of the main departments engaged in this work.

Advertising

In the first article of this series I mentioned only two of these departments as being fundamental units of organization, sales and advertising. That was because the other departments are usually subsidiary functions of the sales department. Not infrequently sales and advertising will also be under one head, but they are more apt to keep their own identity, and therefore deserve to be considered fundamental units. In discussing this work we shall adhere to our original classification and take up advertising first and then all the rest of the functions under sales.

In this discussion of advertising we are forced to leave the chemical field for our models. The question, How shall advertising be done? cannot be answered by the chemical industry. With the exception of perhaps half a dozen large corporations chemical advertising is rather unintelligent. It is unintelligent because it is generally not well advised. Good advertising men are not used.

There is rather a valid excuse for this, however. It is this. Advertising technique seems at first glance to be simple. As a very able advertising man once remarked, "Every American business man believes that he is preeminently competent to criticize advertising copy and organize an advertising campaign, whereas nothing could be farther from the truth." The result is that at first business men are very apt to underestimate the value of an advertising department. The first industries to appreciate its value have been those selling to the general public. Their advertising departments have been able to show conclusive proof of more efficient expenditure and greater net results. The chemical industry does not sell to the general public and has been slower, therefore, to understand the value of advertising and of the advertising department.

Relation to Sales Department

If you will recall the definition given of the advertising function, it was "to interest the prospective customer in the product." It is the second step in marketing the product and must very obviously be closely co-ordinated with other marketing effort. Co-operation is really not a strong enough word to indicate the relationship which should exist between advertising and sales. United is more accurately descriptive if we remember that this should not mean a complete merger of identity. The advertising manager must be intimately familiar with all of the other steps of marketing. He is the only one who needs to be in this position. All of the other marketing units such as sales engineering, credit, traffic, etc., function fairly independently. Not so with advertising. The manager must study the sales engineering or research work, the demand for the goods, the distribution of the market, competition, merchandising methods, policy of price regulation. These things he must correlate with the details of advertising policy. He therefore acts as a consultant in the marketing field. By the very requirements of his work he is in a position to get a perspective of marketing which is unique.

The work of the advertising department falls naturally into three parts: 1. Planning. 2. Production. 3. Statistical.

For this discussion we shall devote most of our time

The first article in this series appeared in Chem. & Met., vol. 26, No. 15, p. 679, April 12, 1922.

to planning. The technique of producing advertisements is too complicated for treatment in an article of this kind. There are many excellent books which take up this subject, and none of them contains less than several hundred pages. It would be impossible even to list and balance the factors which must be considered in constructing advertisements. Men who have such work in charge correspond to high-grade technical men in other departments. They have artists, draughtsmen, copy writers, photographers to assist them. In a large department such men are called creative men. They must be capable of translating advertising policy into a message through one of the many methods of advertising. The production unit of the advertising department will vary in size as greatly as the production unit in a plant: from zero on the one hand where the department depends on the agency or the publishing house for practically everything, to units which in addition to large staff of specialists will have their own engraving done and send the finished plates to periodicals. The needs and temperament of the business will determine the kind of production unit.

Similarly the statistical work of the advertising department may be negligible, with scarcely an adequate record of the kind of advertising placed. Or it may be of the most elaborate kind, including tables of sales or other returns classified by the medium used, the time of year or month, the territory, the salesman and in combinations of these classifications. Then there can be costs per unit sold or per unit advertising depending on the judgment of the head of the department and the kind of results desired.

Planning

We are mainly interested, however, in the planning. It is here that the advertising manager displays his deftness in co-ordinating advertising effort and sales policy. It is the most important part of the advertising manager's work. Good drawing, good copy, good layouts, good choice of medium, all go for naught unless they are part of a plan harmonious with sales effort. Examples without number indicate the loss which results from a petty jealousy or lack of co-operation between sales and advertising.

Therefore before making any plans the advertising manager should absorb (and perhaps modify or create) marketing policy. With that as a foundation he can begin to build toward a definite result. Advertising should strive for a definite result almost quantitatively expressed.

Naturally the size of the appropriation is closely tied to the results desired. You can't buy a Rolls-Royce when you can only afford a bicycle. Neither can you reach the ten million people, nor ten industries, nor the automobile accessory men in ten states when you can afford only one of each. So we have two factors to determine first, the result desired and the appropriation. Usually the board of directors determines the appropriation and the advertising department does its best with what it can get. The department, however, should be able to supply the board with programs of what can be accomplished with various given amounts.

Distribution of Advertising

Given an aim and an appropriation, the most difficult problem is that of distribution.

Shall we use direct advertising, periodical advertising or poster advertising?

Those are the three classes of advertising which are usually differentiated. Direct advertising may not be an obvious term. It includes all forms of advertising which are specifically addressed to an individual. Usually this takes the form of mailing circulars, catalogs, letters or advertisements.

By far the largest annual expenditure for advertising is for periodical advertising, including newspapers, magazines, programs, etc. This does not mean that periodical advertising is the best kind of advertising. There is no "best kind" in general. Practically all of the Sears-Roebuck appropriation goes into direct advertising, whereas for years Campbell's soups appeared only on posters and car cards. Each advertiser has a different problem, a different group of prospective customers, a different appeal, and consequently would choose different media. It is obvious that the problem of distributing advertising is one which should command experience and knowledge of advertising technique. On what basis except experience can there be any preference for one method as against another? The only other basis is the royal game of guess, in which the ordinarily shrewd business man seems to like to indulge. It is incidentally a convenient way of accounting for poor advertising.

Chemical Advertising

It has seemed to me rather obvious that, in general, chemical advertising could be limited to direct advertising and advertising in technical and trade periodicals. With a definite and limited list of prospective consumers, manufacturers of chemicals and chemical equipment do not have the difficult problems of national advertising to face nor yet those of local advertising to the general public. (The few exceptions to this general rule, chemical manufacturers whose products go to the general public, are in a healthier condition in regard to advertising policy than the rest of the industry and will be neglected in this article.)

Evidence is at hand that there are advertisers who do not agree with the above thesis. A large manufacturer of equipment recently appeared in some full-page displays in the *Saturday Evening Post*. For the price of one page he could have covered his six biggest consuming industries for a year in the technical and trade magazines. That is one example of unintelligent advertising.

Again, a manufacturer of chemicals spent nearly a thousand dollars putting little $\frac{1}{16}$-page announcement cards in trade periodicals and did not back up the campaign with proper sales support. He received three inquiries—from dealers—in the course of a year. He was depending on his advertising to make sales, an ill-conceived policy, expensive no matter how few dollars and cents are involved.

These two advertisers represent the two extremes—the profligate spending of a large and poorly estimated appropriation on the one hand and the self-advised throwing away of a small amount of money on the other. Most chemical advertising resembles the second example. The attitude of the advertiser lies midway between that of a patron of art bountifully bestowing a largess and that of a skeptic who, though he does not believe in vaccination, nevertheless for his own peace of mind grudgingly pays a physician to be inoculated. The idea that advertising is an aid to marketing and is a study conducted by experts on scientific principles has not seemed to occur to the chemical advertiser.

The point I am anxious to make is this: Chemical

manufacturers must realize that their advertising problems should be solved with the aid of the advertising experts. Otherwise their money is apt to be wasted.

Indirect Advertising

There are other methods of advertising—indirect methods. They have value, although they are not usually included in advertising appropriations. Manufacturers of high-grade automobiles sometimes make it a practice to keep cars of their make looking well. When they see a dilapidated car they approach the owner with offers to trade it in or have it fixed up. An analogous procedure exists in the follow-up of some firms to make sure their customers are satisfied.

One enlightened firm sends some of its technical representatives to the various conventions at which consumers of its products are likely to be found. No soliciting is done, but the good appearance and friendliness of these men create a very favorable tone.

The trouble work, so called, or sales service, which will be discussed later, is a splendid advertising aid. One satisfied customer is worth a number of prospects; the exact number depends on the product and might vary from two or three with acids to say fifty with dyestuffs.

Every point of contact with other firms presents an opportunity to create favorable or unfavorable impressions and to build up assets and liabilities. The policy of collecting accounts may lose friends. The purchasing agent may leave a bad impression on salesmen. The company's salesmen in particular are ambassadors reflecting policy. All of these contacts are indirect advertisements and should come under the scrutiny of the advertising manager.

The Advertising Agency

If I had been made advertising manager of a company I should certainly not begin to talk about advertising agencies at once. It would be poor psychology. Presumably the board of directors would assume that I was trying to get someone to do my work for me. Few persons realize that the advertising department and the advertising agency are complementary and not interchangeable. The point at which the department stops and the agency begins varies with each company. One firm may have an advertising manager and two or three stenographers or clerks who simply keep records. In such a case the agency would co-operate in planning the campaign, produce all the drawings and literature necessary, take charge of accounting, etc. The same agency may have a client with a large staff of advertising men, artists, compositors, as well as routine clerks, etc. In such a case the agency acts in an advisory capacity only.

In any national advertising the advantages of dealing with an agency are very great. Its wealth of experience can be focussed on the problem of the individual firm to great advantage. It cannot displace the advertising department, however. Experience has shown that it is very wise to have the point of view of someone inside the organization turned on these problems. Several large companies have experimented with this plan and abandoned it.

There is less evidence of the value of the agency in technical advertising. There has been less of it for them to do and in addition many accounts were and are still unwisely undertaken by agencies—accounts about which they know very little. Their advice is therefore either superficial or obtained from technical publishers. So widespread has this been that a large number of technical publishers have instituted their own advertising service. Some have all the facilities of first-class agencies at their disposal and are able to plan for clients a campaign of advertising which will put their product before that part of the technical world which will be interested.

In general then the agency has yet to prove its value in technical advertising, but has won a deserved place in the counsels of national advertisers.

There have been no figures given here to show the value of advertising. That has not been the purpose of the discussion. Such figures are easily available, even in our backward industry. A firm which tries to market without obtaining the advice of an advertising expert and finding out whether and how he should advertise is like the man who lit a candle and put it under a bushel basket. It is a waste of light. Rather set it on a candlestick and use the lenses and reflectors of advertising so that the light will go where it will do most good.

A word of caution to technical men may be in order. Our confessed attitude in these articles has been how valuable technical training is in non-technical departments. In the case of advertising, however, technical men will find their training of least value. It would be difficult to justify a technical course as a preparation for advertising. Other things would be so much more worth while. Every position, technical or non-technical, should be approached with humility but with perhaps confidence. If you are drawn toward advertising, take it up with more humility and less confidence but with great optimism. The future is there for the department and for the man who creates and develops it.

Indications of a Finished Heat in Acid Electric Furnace*

By James L. Cawthon, Jr.

In the acid way, a percentage of silicon may be reduced from the slag. Under certain conditions, if the temperature is permitted to get high, the slag highly acid and the furnace condition highly reducing, a considerable amount of silicon will be reduced from the slag. The action which produces this takes place at a very rapid rate, conditions being propitious, and a closer analysis may be obtained if this condition be avoided, relying entirely upon a ferrosilicon addition.

All three of the conditions mentioned above are necessary to silicon reduction, and by modifying any one of them it can be stopped instantaneously. The simplest method is to introduce a small amount of fireclay or lime immediately under the electrodes. To the operator experienced in acid electric furnace operation, the condition is immediately apparent by several signs, among them being the almost total silence of the arcs, the extreme paucity of fumes around the electrodes and the general "tightness" of the furnace.

It may be added here that this condition which comes about in the acid electric furnace is indicative of a highly deoxidized condition of the bath. Tests taken from heats under this furnace condition show the metal to be in excellent condition. Its use, with proper judgment and understanding, may therefore well be adopted. Some steel foundries regularly permit a heat to come to this condition incipiently before tapping, the results being reflected in the soundness of the castings.

*Extract from a paper on "Synthetic Cast Iron," read before the Baltimore meeting of the American Electrochemical Society, April 27, 1922.

Studies in the Carbonization of Coal: Characteristics of Low-Temperature Coal Tar*

Outline of a Scheme of Examination for Tars Obtained in the Low-Temperature Carbonization of Coal—Composition of a Commercial Low-Temperature Tar and Comparison With Coke-Oven and Gas-Works Tars—Review of Results Obtained by Previous Investigators

BY JEROME J. MORGAN AND ROLAND P. SOULE
Department of Chemical Engineering, Columbia University

THE present report is the first of a projected series of studies in the carbonization of coal. It concerns itself primarily with an examination of a low-temperature coal tar, but its scope has not been confined to specific analytical data. In the absence of any standard analytical procedure in this little explored field, it has become necessary to develop a scheme of examination by which the component groups of low-temperature tars may be readily examined. An intensive investigation has been made of a commercial low-temperature tar, comparing the analytical results obtained with those of other tars. This scheme and the character of the tar determined by it are described in the present paper.

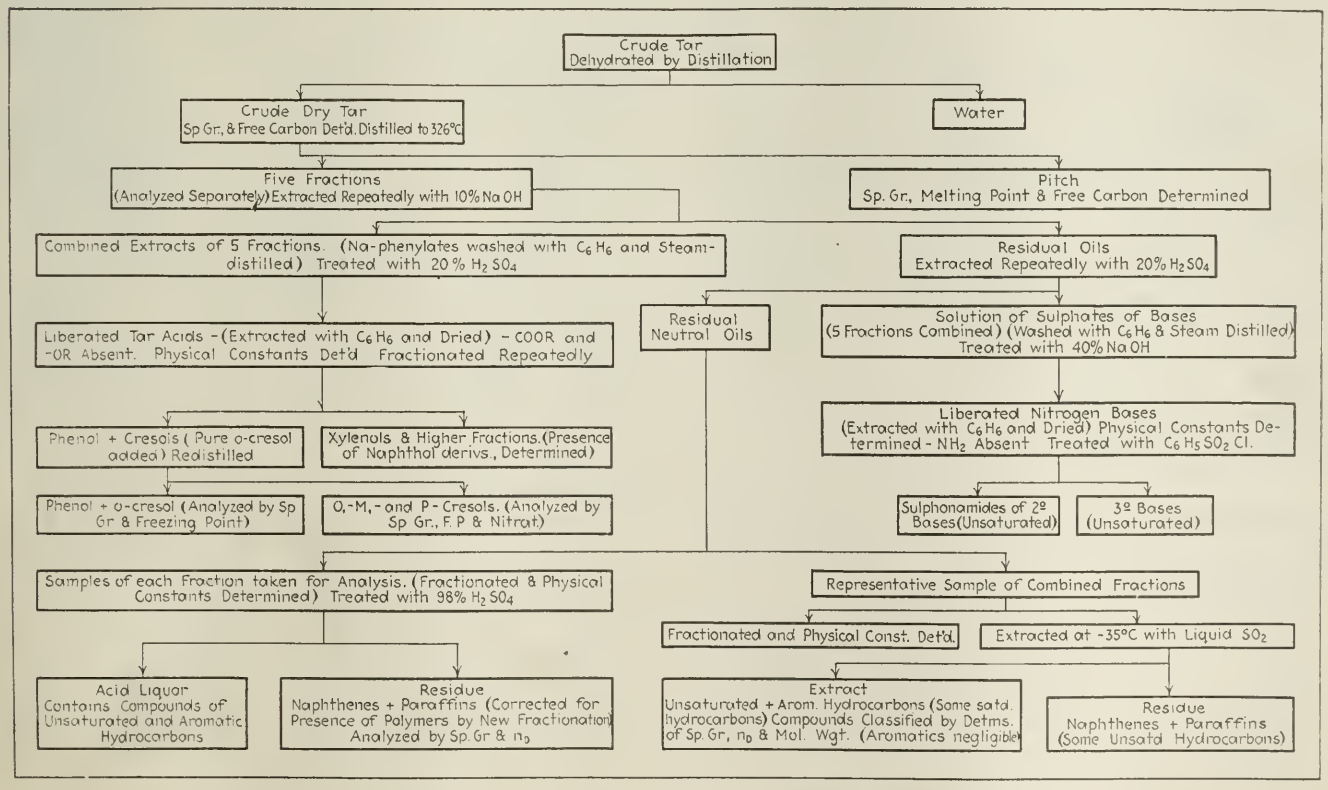
The composition of this tar indicates a stage in the decomposition of the primary liquid distillates of coal which hitherto has not been carefully studied. In a second installment it is intended to define more precisely several distillation reactions, and to present a new viewpoint on the much disputed mechanism of the carbonization of coal. Thus, a rational basis will be found for reconciling to a large extent the reported differences in the composition of low-temperature coal tars.

Until recently the commercial carbonization of coal has been performed at 1,000 to 1,300 deg. C. primarily for the production of city gas and metallurgical coke. Within the past decade, however, lower temperatures of distillation have been made to serve two purposes. The first of these is scientific in nature—the study of the products of distillation at various temperatures has shed light on the constitution of coal, and afforded evidence for theories of carbonization. The second object has been the production of new materials of commercial value. By distilling an ordinary bituminous coal at 500 to 600 deg. C. there are obtained a friable, free-burning coke which may be made to serve as a smokeless fuel, and a distillate which upon removal of the phenols resembles crude petroleum in properties and uses.

*Condensed from a thesis presented by Roland P. Soule in partial fulfillment of the requirements for the degree of Doctor of Philosophy in the Faculty of Pure Science of Columbia University in the City of New York.

OUTLINE OF INVESTIGATION

An outline of the type of methods used in the present investigation is given in Fig. 1. According to this pro-



Crude Tar
Dehydrated by Distillation
Crude Dry Tar
Sp Gr, & Free Carbon Det'd. Distilled to 326°C
Water
Five Fractions
(Analyzed Separately) Extracted Repeatedly with 10% Na OH
Pitch
Sp. Gr., Melting Point & Free Carbon Determined
Combined Extracts of 5 Fractions. (Na-phenylates washed with C_6H_6 and Steam-distilled) Treated with 20% H_2SO_4
Residual Oils
Extracted Repeatedly with 20% H_2SO_4
Residual Neutral Oils
Solution of Sulphates of Bases
(5 Fractions Combined) (Washed with C_6H_6 & Steam Distilled) Treated with 40% Na OH
Liberated Tar Acids - (Extracted with C_6H_6 and Dried) - COOR and -OR Absent. Physical Constants Det'd Fractionated Repeatedly
Liberated Nitrogen Bases
(Extracted with C_6H_6 and Dried) Physical Constants Determined - NH_2 Absent Treated with $C_6H_5SO_2Cl$.
Phenol + Cresols (Pure o-cresol added) Redistilled
Xylenols & Higher Fractions. (Presence of Naphthol derivs., Determined)
Phenol + o-cresol (Analyzed by Sp Gr & Freezing Point)
O.-M.- and P.- Cresols. (Analyzed by Sp Gr., F.P & Nitrat)
Sulphonamides of 2° Bases (Unsaturated)
3° Bases (Unsaturated)
Samples of each Fraction taken for Analysis. (Fractionated & Physical Constants Determined) Treated with 98% H_2SO_4
Representative Sample of Combined Fractions
Fractionated and Physical Const. Det'd.
Extracted at -35°C with Liquid SO_2
Acid Liquor
Contains Compounds of Unsaturated and Aromatic Hydrocarbons
Residue
Naphthenes + Paraffins (Corrected for Presence of Polymers by New Fractionation) Analyzed by Sp. Gr & n_D
Extract
Unsaturated + Arom. Hydrocarbons (Some satd. hydrocarbons) Compounds Classified by Detms. of Sp. Gr, n_D & Mol. Wgt. (Aromatics negligible)
Residue
Naphthenes + Paraffins (Some Unsatd Hydrocarbons)

Résumé of Earlier Studies

Low-temperature coal tar may best be defined as the tar produced by the carbonization of coal at temperatures (500 to 750 deg. C.) not high enough to cause an appreciable decomposition of the primary liquid products of distillation.

Certain circumstances must be borne in mind in attempting a comparison of previous investigations of low-temperature tars. The low heat conductivity of coal makes the exact nature of tars distilled at approximately the same temperature dependent upon such factors as agitation, rate of distillation, the thickness of the fuel layer and the resulting temperature gradient. Moreover, the extent to which secondary reactions may also occur is determined by the pressure employed, the use of steam, the size of the gas space, the temperature of the crown of the retort and other conditions controlling the path of the gases.

Of the several investigations of one aspect or another of low-temperature tars, four studies are cited in Table II as the most important and representative efforts toward a through analysis. A. Pictet[1] and his co-workers in Switzerland and D. T. Jones and R. V. Wheeler[2] in England employed the tar as an agent in their re-

searches on the constitution of coal. S. W. Parr[3] and his associates in this country were primarily interested in the commercial aspects of low-temperature carbonization, as were F. Fischer[4] and his staff in the Kaiser-Wilhelm Institute of Coal Research in Mülheim-Ruhr, Germany. The details tabulated in the case of Fischer's work represent only one of a large number of related experiments, but serve to indicate his characteristic method of reporting tar investigations in technical rather than in scientific terms. For the purpose of comparison the results obtained in the present investigation are also included in this table.

Origin of the Tar Examined

The tar examined was produced by the "Carbocoal" process[5] (C. H. Smith patents) of the International Coal Products Corporation. It was a representative sample made in March, 1921, under commercial conditions at the experimental plant of the company at Irvington, N. J.

The low-temperature tar produced by the *primary* retorts is the subject of this investigation. These retorts are horizontal, about 18 ft. long, and of cardioid section. The walls are constructed of carborundum blocks, and the ends of cast iron lined with firebrick. The coal is continuously stirred and advanced through the retort by paddles of radius 2 ft. 3 in. mounted on two parallel 12-in. paddle shafts, which revolve at 1.8 r.p.m. Each retort is operated about one-third full, and has sufficient capacity to permit an output of 1 ton an hour. The products of distillation leave at the top of the discharge end of the retort. The temperature in the retort shell is about 730 deg. C., in the gas at the feed end of the retort 300 deg. C. and at the discharge end about 500 deg. C. The temperature of the discharged coke approximates 480 deg. C.

It is apparent from this description of retort conditions that the opportunities for secondary decomposition are not negligible. Thus the outgoing products of distillation come into contact with surfaces heated to 600 deg. C. and undergo decomposition to some extent.

A Pennsylvania bituminous coal known as "Pittsburgh Terminal" coal was used in the preparation of the sample of tar examined. Its analysis[6] on a dry basis is given in Table II. The moisture content of the coal as fed into the furnace amounted to 2 per cent. The calorific value was 13,925 B.t.u. per lb.

Properties of the Tar and Pitch

Dehydration and Distillation. Carbocoal tar, in common with other low-temperature tars, is a black oil of petroleum-like fluidity. It smells strongly of cresols and to a less extent of hydrogen sulphide. The viscosity is lower than that of ordinary coke-oven and gas-works tar, and no odor of ammonia or naphthalene can be detected in it.

The tar was dehydrated for subsequent examination by distilling to 200 deg., separating the light oil from the water in the condensate and returning it to the main body of tar remaining in the still. A specially constructed 3-gal. copper tar-still of the same proportions as the Barrett type[7] was used in the operation. About 8 kg. of tar was distilled at a time. The content of water in the sample of tar amounted to 2.12 per cent.

A sample of thoroughly mixed, crude, dry tar was taken for specific gravity (Hubbard bottle) and "free carbon" determinations according to standard procedures[7]. A dry distillation of the 8 kg. of crude tar thus dehydrated was made at atmospheric pressure in the same copper still. The rate was 15 c.c. per minute, or about 0.2 per cent of the total volume of tar per minute. For comparison samples of coke-oven tar[8] and gas-works tar[9] were fractionated in exactly the same manner and the results are recorded in Fig. 3 and Table III.

TABLE III—FRACTIONATIONS OF REPRESENTATIVE TARS[10]

Fraction B.P. Range Deg. C.	Percentages of Total Weight—Low-Temperature Tar	Coke-Oven Tar	Gas-Works Tar
20–173	0.64	0.70	1.19
173–237	9.19	8.27	9.22
237–281	12.50	12.44	10.12
281–315	6.94	6.21	3.78
315–326	2.90	2.53	1.93
Pitch (diff.)	67.83	69.85	73.76
M. P. of pitch, Deg. C.	53	69	89

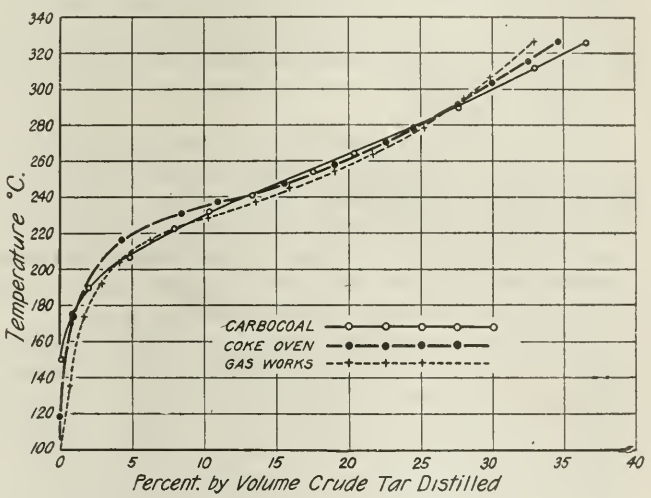

FIG. 3—DISTILLATION OF CRUDE, DRY TARS

In general there is a close resemblance between the three fractionation curves, disproving the many exaggerated statements that have been made of the larger quantity of low-volatile oils in low-temperature coal tars. The percentage of pitch is only slightly lower in this tar than in the high-temperature tars, although the difference would be greater with higher cutting temperatures, or if the distillates had been carried to a pitch of the same melting point in each case, as commercial conditions might demand. Thus, when Carbocoal tar is carried to a pitch melting at 80 deg. C. for use in briquetting, only 56 per cent remains in the still.

Pitch. The pitch obtained from the low-temperature tar was an amorphous, black residue, which lacked the brittleness and lustrous fracture of high-temperature pitches. Briquets made from it lost their sharp edges

TABLE IV—COMPARISON OF TARS AND PITCHES

	Low-Temperature	Coke-Oven	Gas-Works
Crude, dry tar			
Sp.gr. 15.5 deg./15.5 deg.	1.0676	1.1845	1.2172
"Free carbon," per cent	0.71	6.93	20.1
Pitch, cut at 326 deg.			
Sp.gr. 15.5 deg./15.5 deg.	1.134	1.263	1.312
"Free carbon," per cent	2.17	16.8	31.1
Air melting point, deg. C.	53	69	89

within an hour at room temperature. The specific gravity (Hubbard bottle), "free carbon" and air melting points of the Carbocoal, coke-oven and gas-works tars and pitches were determined by standard procedures, and are recorded in Table IV.

The Phenols

The high content of phenols in low-temperature tars has been remarked by nearly all investigators (*cf.* Table II), and within certain limits may be accepted as an important characteristic distinguishing them from high-temperature tars.

Removal From the Tar. The percentages of phenols were determined separately in each of the five fractions (*cf.* Table III). In the method used, 100 g. of a fraction was weighed into a 200-c.c. glass-stoppered separatory funnel, and extracted four times each with 50 c.c. of 10 per cent sodium hydroxide solution. The loss in weight of each sample checked against the gain in weight of the alkali used was taken as the percentage of tar-acids present.

Fig. 4 was obtained by plotting percentages of tar-acids against the average boiling points during distillation of the corresponding tar fractions, taken as the mean ordinates of the respective sections of the distillation curve of Fig. 3. It shows a well-defined maximum between 240 and 280 deg., and indicates that a large quantity of tar acids is contained in the pitch.

Purification of the Tar-Acids. The fractions of low-temperature tar were washed completely free of phenols with 10 per cent sodium hydroxide solution. The alkaline solution, after purification by benzene extraction and steam distillation, was acidified with 20 per cent sulphuric acid to liberate the phenols, as indicated by Fig. 1. The tar-acids thus recovered formed a dark brown, slightly viscous liquid, which had a strong odor of cresols.

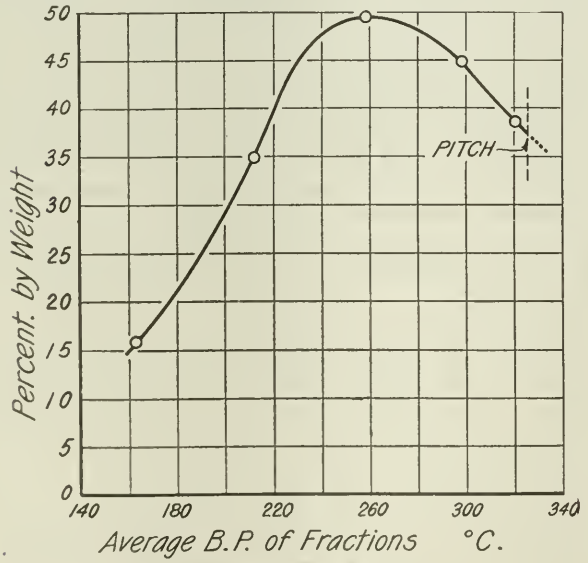

FIG. 4—RELATION OF THE BOILING POINTS OF TAR FRACTIONS TO PHENOL CONTENT OF EACH

Carboxylic Acids. No solubility of this mixture in a saturated sodium carbonate solution could be detected, and a sample after solution in sodium hydroxide was completely recovered by precipitation with carbon dioxide. Carboxylic acids, therefore, could be admixed with the phenols only to a negligible extent.

None of the four investigators quoted above has reported such compounds, but recently Marcusson and Picard[11] found in a low-temperature tar from upper Silesian coal a solid mixture of 13 per cent phenols and 12 per cent aromatic carboxylic acids. Tropsch[12] distilled under similar conditions a coal from the same region, however, and found viscous, not solid phenols, with only traces of solid carboxylic acids. He stated that the tar described by Marcusson and Picard was probably exceptional.

Phenol Ethers.—The occurrence of guaiacol in wood-tar[13] and in peat-tar,[14] both of which are formed by carbonization below 500 deg. and resemble low-temperature coal tars in their high content of phenols, suggests the possible presence in the latter of phenol ethers. A negative Zeisel test, however, showed that methoxyl and ethoxyl groups are absent from the phenol mixture obtained from the low-temperature tar.

A similar result has been reported[15] for the phenols from Lohberg coal tar (*cf.* Table II).

Polyhydroxy Phenols. The water obtained simultaneously with the tar in the distillation of the coal in the low-temperature process was not available for the present investigation. Since this liquor contained the largest proportion of polyhydroxy phenols distilled from the coal, their estimation in the tar was not attempted.

Catechol has been identified[16] among the products of low-temperature distillation of Lohberg coal, and was estimated to be present to the extent of 0.02 per cent of the weight of the coal.

Fractionation and Density Determinations

The phenol mixture from the low-temperature tar had a specific gravity[17] of 1.036 at 25 deg./4 deg. as compared with 1.044 of the mixed coke-oven and gas-works phenols extracted with 10 per cent sodium hydroxide at 60 deg., and purified in the same manner as the low-temperature phenols. Fractionation curves of the two types are seen in Fig. 5.

It is evident that in the first-named mixture there are no phenols of boiling point higher than may be found among the high-temperature phenols. The proportions of the components, however, differ quite markedly, 52 per cent by volume of the low-temperature phenols boiling below 220 deg., as opposed to 77 per cent of the phenols from coke-oven and gas-works tar. In both cases these percentages may be increased considerably by continued fractionation.

[17]Unless otherwise specified, all densities cited in this investigation were determined by use of a Becker analytical balance and a 7 g. glass plummet immersed in the liquid, which was jacketed with water at the desired temperature.

To obtain a more informative comparison of the low- and high-temperature phenols, each series was slowly distilled four times with a Young four-pear head, dividing the distillate into eight fractions. The specific gravity at 25 deg./4 deg. of each was determined, and plotted in Fig. 6 against the average boiling point of that fraction, taken as the mean ordinate of the boiling-point curve of the final fractionation in each case.

The decrease in the specific gravity of the phenols as the boiling point increases indicates the presence of

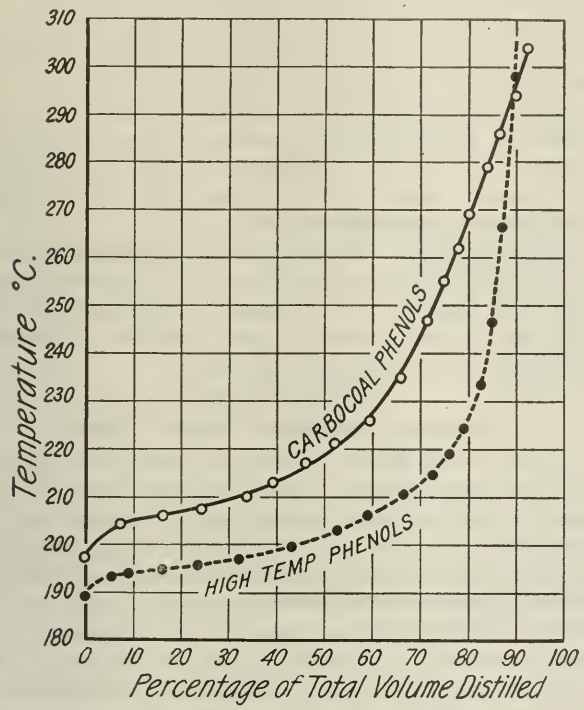

FIG. 5—DISTILLATION OF PHENOLS

aliphatic sidechains of lower density attached to the phenol nucleus—e.g., cresols and xylenols. In the higher homologs a sharp rise in density and a notable increase in the viscosity of the fractions mark the appearance of α- and β-naphthols[18] in the high-temperature phenols, and bicyclic compounds at least in the low-temperature phenols.

These higher homologs have been investigated,[19] and found to contain naphthol derivatives, as the wide divergence of the two curves suggests, but neither α- nor β-naphthol. However, the coincidence of the first section of the curves indicates that the Carbocoal mixture contains the same low-boiling components as the high-temperature phenols, although the proportion is much smaller.

TABLE V—FRACTIONATION OF PHENOLS FROM LOW-TEMPERATURE TAR

No.	Fraction, Deg. C.	Weight in G., Fraction	Per Cent of Total Phenols	No.	Fraction, Deg. C.	Weight in G., Fraction	Per Cent of Total Phenols
1	182–189	41	7.3	6	214–220	44	7.9
2	189–195	38	6.8	7	220–227	14	2.5
3	195–202	60	10.8	8	227–260	102	18.3
4	202–207	71	12.7	9	260–300	92	16.5
5	207–214	48	8.6	10	Pitch	48	8.6
					Total	558	100.0

Another sample of the mixed phenols was fractionated once each with a Young four-pear and a 10-in. Vigreux column, and then five additional times below 230 deg. with the Vigreux head. The average rate of distillation was 1 c.c. per minute, or 0.2 per cent by volume per minute. The results, corrected for the slight distillation losses, are recorded in Table V.

The specific gravity and bromine tests of Fraction 1 indicated the presence of phenol. Fraction 2 showed with ferric chloride the characteristic color reaction of *o*-cresol. In classifying these fractions it is customary to assume that if the cut is made midway between the boiling points of two components, the quantity of the higher-boiling compound appearing in the lower fraction will be approximately balanced by an equal amount of the lower-boiling compound in the higher fraction. Subsequent experiments have shown this assumption to be justified. On this basis Fractions 1 through 4 contain phenol and the cresols (210 g.; 37.6 per cent); Fractions 5 through 7 contain the xylenols (106 g.; 19.0 per cent); and Fractions 8 through 10 contain the higher homologs (194 g.; 34.8 per cent).

Estimation of Phenol and the Cresols

The general scheme employed is that indicated in Fig. 1. The phenol and cresols, separated from the higher homologs by 15 fractionations, amounted to 35.0 per cent (uncorrected for distillation losses; *cf.* 37.6 per cent above) of the total phenols. Since *m*- and *p*-cresols preponderated in the mixture thus obtained, pure *o*-cresol was added to accomplish a sharper separation by distillation into two fractions, one comprising essentially phenol and *o*-cresol, and the other a mixture of the three cresols.

These fractions were analyzed separately by methods

TABLE VI—COMPOSITION OF THE LOW-TEMPERATURE PHENOLS

Component	Percentages by Weight, Phenols	Basis of Distillate	Crude Tar
Phenol	4.2	1.9	0.6
Cresols *a*	33.4	15.2	4.9

involving nitration[20] and the determination of density and freezing points.[21] Table VI shows the composition of these phenols.

Comparison With Previous Investigations

The yield of tar in the Carbocoal process from the particular coal in question is 225 lb. per ton, or 11.3 per cent. This is higher than any other yield reported in Table II. The reason for this lies to a large extent in differences in the composition of the coal used by various investigators, as indicated by Table VII.

TABLE VII—COMPARATIVE YIELDS OBTAINED IN VARIOUS INVESTIGATIONS

Investigation	Temp. of Distillation, Deg. C.	Time of Distillation	Tar Yield Per Cent V.C.M. in Coal	Tar Yield Per Cent Wgt., Coal	Per Cent Tar-Acid Dist.	Per Cent Tar-Acid Tar
Pictet	450 max.	5 hr.	15–20	4.0	....	8
Jones & Wheeler	430	5 wks.	26–31	6.5	12–15	6–8
Parr	450–525	6-8 hr.	35	8.7	40	28
Morgan & Soule	500–600	3 hr.	35	11.3	43	13
Fischer	350–500	1-2 hr.	39	10.0	..	50

For the purpose of comparison it may be noted in connection with this table that the distillation of a 30-55 per cent volatile coal in a coke oven at 900-1,000 deg. C. yields from 4 to 6 per cent of tar. The phenols recovered from the coke-oven and gas-works tar mentioned above averaged about 9 per cent by weight of the distillate, or 2.5 per cent of the total tar.

It must be borne in mind in studying these results that Pictet and Fischer alone actually removed the phenols from the entire tar, and that the percentages of tar-acids in the total tars reported by the others are consequently somewhat too low. As an added complication, Parr[3] reports a decrease in the yield of tar-acids with a decrease in the amount of steam used in the distillation of the coal. In general, however, it will be observed that the content of phenols increases with a rise in the volatile content of the coal from which it was distilled, and hence with the actual yield of tar. It seems apparent, therefore, that this increase in bulk of the tar is due largely to phenols.

The comparison of Table VII is superficial, however, and the underlying cause of this relationship is probably not so simple a matter as the mere volatile content. It has been shown[22] that the phenols owe their origin to the fraction of coal insoluble in pyridine and chloroform (the so-called "cellulosic" constituent), which is not a direct function of the volatile content. A low content of phenols in a tar, therefore, cannot be taken as direct evidence of a high temperature of coal carbonization unless the constitution of the coal distilled is also taken into consideration.

Previous Analyses of Low-Temperature Phenols

Jones and Wheeler[2] collected the fraction of phenols distilling between 100 and 145 deg. C. at 30 mm. (d. 1.037 at 15 deg./15 deg.), and from its ultimate analysis concluded it to consist essentially of a mixture of cresols and xylenols. Pictet[1] stated that the phenols obtained in fresh Montrambert "vacuum tar" have a very high boiling point, crystallize easily and contain no phenol, cresols or xylenols. Among the phenols which appeared on standing in a sample of tar prepared 5 years before, he was able to identify phenol itself, the three cresols and 1:2:4 xylenol by qualitative tests.

Fischer[23] reported the 45 per cent of phenols from Lohberg gas coal to contain 0.25 per cent catechol, 0.06 per cent phenol, 1 to 2 per cent cresols, 1 to 2 per cent xylenols, 30 to 32 per cent higher-boiling than xylenols, and 10 per cent acid resins. Phenol was determined by a freezing-point method[24] in a mixture obtained by fractional neutralization of the tar-acids. The cresols were studied by a development of Lederer's chloracetic-acid method[25] using Raschig's nitration method[20] as an alternative procedure for *m*-cresol. The amount of *m*-cresol was about one-quarter of the total cresols, which checks roughly the 19 per cent found in the cresols from low-temperature tar.

EDITOR'S NOTE: This study of the characteristics of low-temperature tar is to be concluded in a second paper which will appear in a subsequent issue and will describe the nitrogen bases, alcohols, sulphur compounds and hydrocarbons present in the tar.

Census of Industrial Power Plants

When the 1919 census was taken, there were 290,105 industrial establishments being operated in the United States. They employed $44,688,093,771 capital and an aggregate horsepower of 29,575,242. These establishments employed 10,160,107 wage earners in addition to 1,447,227 officers, superintendents and other salaried employees. The figures are those of the Bureau of the Census, grouped in a special form for the use of the Senate, in connection with its study of the tariff.

The amount of fuel used by these industrial plants is as follows: Bituminous coal, 203,452,724 short tons; anthracite coal, 14,545,300 long tons; coke, 42,764,287 short tons; oil, 92,608,186 bbl.; gasoline, 2,344,469 bbl.; natural gas, 305,768,321,000 cu.ft.; manufactured gas, 38,522,330,000 cu.ft.

At 237,855 of these plants 116,158 steam engines furnished 13,839,744 hp.; 6,472 steam turbines furnished 3,258,235 hp.; 33,407 internal combustion engines furnished 1,259,394 hp.; 13,244 waterwheels furnished 1,753,548 hp.; 817 water motors furnished 22,165 hp. In addition to the foregoing equipment which is owned by the establisment, 9,442,156 hp. is furnished by rented equipment. Of that amount 9,347,556 hp. is furnished by 996,000 electric motors. The remaining horsepower generated with rented equipment amounts to 94,600.

Explosives Production in 1921

A decrease in the quantity of explosives used in the United States in 1921 as compared with 1920 is shown by a falling off of 37.2 per cent in sales of black powder, 25.4 per cent in high explosives, and 23.8 per cent in permissibles. The total sales amounted to 372,107,503 lb., as compared with 537,954,750 lb. the year before. Of this total, 160,021,250 lb. was black blasting powder, 170,952,402 lb. high explosives other than permissible explosives, and 41,133,851 lb. permissible explosives.

Fine Steels From the Acid Open Hearth*

Discussion of the Underlying Principles and Necessary Furnace Practice for the Production of High-Grade Nickel Steel for Gun Tubes and Shafting—Comparison of the Pig, Scrap and Ore Process Used in America With the All-Scrap Practice Used in Europe

STEEL for gun tubes and heavy shafting is usually tested tangentially, and should develop the following physical properties, depending upon its use:

Ultimate tensile strength..86,000 to 95,000 lb. per sq.in.
Elastic limit .....46,000 to 65,000 lb. per sq.in.
Elongation in 2 in. .....18 per cent
Contraction of area .....30 per cent

To comply with these specifications, especially the maximum, acid open-hearth nickel steels within the following limits of composition are usually supplied by American makers:

	Per Cent		Per Cent
Carbon	0.35 to 0.50	Manganese	0.50 to 0.75
Phosphorus	below 0.05	Silicon	0.15 to 0.30
Sulphur	below 0.05	Nickel	2.50 to 3.75

Charging and Melting

Forty parts of pig iron are usually charged to 60 parts of scrap, not more than 20 per cent of which may be turnings (which oxidize badly in melting). Half the pig iron is put into the furnace, then the scrap, and finally the remainder of the pig. Thus the top layer protects the scrap from undue burning caused by direct impact of the flame, and the lower layer reduces the oxidized drops of molten metal before they reach and corrode the hearth beneath. Composition of the mixture is as follows:

	Per Cent		Per Cent
C	2.0	Mn	1.0 to 1.25
P	less than 0.05	Ni	less than specification
S	less than 0.05	Cr	less than 0.05

Melting should be done with expedition, since the hearth is attacked more or less severely during the early hours.

Sulphur and phosphorus, being substantially unchanged during the heat, should be low. Both of these elements segregate toward the axis of the ingot, and also at the surface of primary austenite crystals, and on forging result in black ghost lines. A surprising amount of manganese remains in the metal, and is throughout a very powerful deoxidizer and desulphurizer. Chromium intensifies the tendency toward laminated fractures in the finished forging, and should be kept to the extreme minimum.

Oring

When the charge is well melted it contains 0.90 to 1.20 per cent C, which must now be removed. A preliminary step is to add 10 lb. $CaCO_3$ per ton of charge and stir it in. It gives off CO_2 gas, which bubbles up through the metal. Boiling or chemical stirring aids the mechanical stirring in heating the cold metal at the bottom of the bath. Cold metal mixes with the hotter upper layers, which in turn have received radiation from flame and roof. The CaO remaining also forms a fusible slag with the oxides formed during melting.

As shown in Fig. 1, in about 45 minutes the temperature of the bath is hot enough so that small amounts of cold ore thrown in from time to time will not chill the adjacent metal and slow down the reactions. For each ton of metal is added 28 to 33 lb. of rich, pure low-phosphorus hematite. Reactions of the type

$$Fe_2O_3 + 3C = 2Fe + 3CO$$

take place; the liquid boils violently. In about 2 hours oring should be complete, the carbon then being some 0.30 per cent above the desired figure, a margin which is needed in the subsequent operations.

Deoxidizing

A rather thin line exists between the oring and the deoxidizing period. In the former, iron oxide was added to rid the bath of excess carbon. Now comes a time when the object is reversed; the reaction is the same, but the residual carbon is used to rid the bath of excess oxide.

Carbon is a good deoxidizer to use, since the product is a gas which easily escapes. In order to proceed with reasonable speed the reaction requires a very high temperature, as high as the roof can stand. Progress is judged by the appearance of the slag crust adhering to furnace tools—as the slag contains less and less FeO, the freshly broken sample becomes more vitreous or waxy, and the color changes from dark brown or black to pale lemon and then to light gray.[1] Toward the end of the carbon reaction, decreasing oxide in the metal may also be recognized by a decreasing number of gas cavities in test ingots, taken periodically.

The principles of physical chemistry indicate that a soluble oxide will distribute itself between two liquids in contact in a definite ratio (which is constant as long as such conditions as temperature and nature of slag remain fixed). Therefore, as the slag loses FeO, it is a sign the metal is also losing oxygen. A light gray slag contains about 15 per cent FeO, and when the heat has progressed this far, the reaction between carbon and FeO has been nearly halted. In fact during the later portion of this stage carbon has been attacking the slag and hearth, reducing SiO_2 and adding up to 0.12 per cent silicon to the metal.

It is of utmost importance, in the manufacture of fine steel, that this high-temperature refining of the metal by carbon be carefully attended and pushed to completion.

When the carbon has fallen to approximately that percentage required for the finished product, as judged by the fracture of a test ingot, a rapid carbon analysis is made, and the word passed to "go ahead" with prepa-

*A digest of a paper entitled "Acid Open-Hearth Process for Manufacture of Gun Steels and Fine Steels," presented by W. P. Barba and Henry M. Howe before the February meeting of the American Institute of Mining and Metallurgical Engineers.

[1]The outer surface of slag samples is always brown, like glazed tile, doubtless on account of oxidation of the cooling ferrous oxide. Use of high-manganese pig has a considerable influence on these slag samples, giving them a strong greenish cast and at times a dark green core. Appearance is also affected by the rapidity of melting, and the kind of hearth, and excessive drippings from the roof.

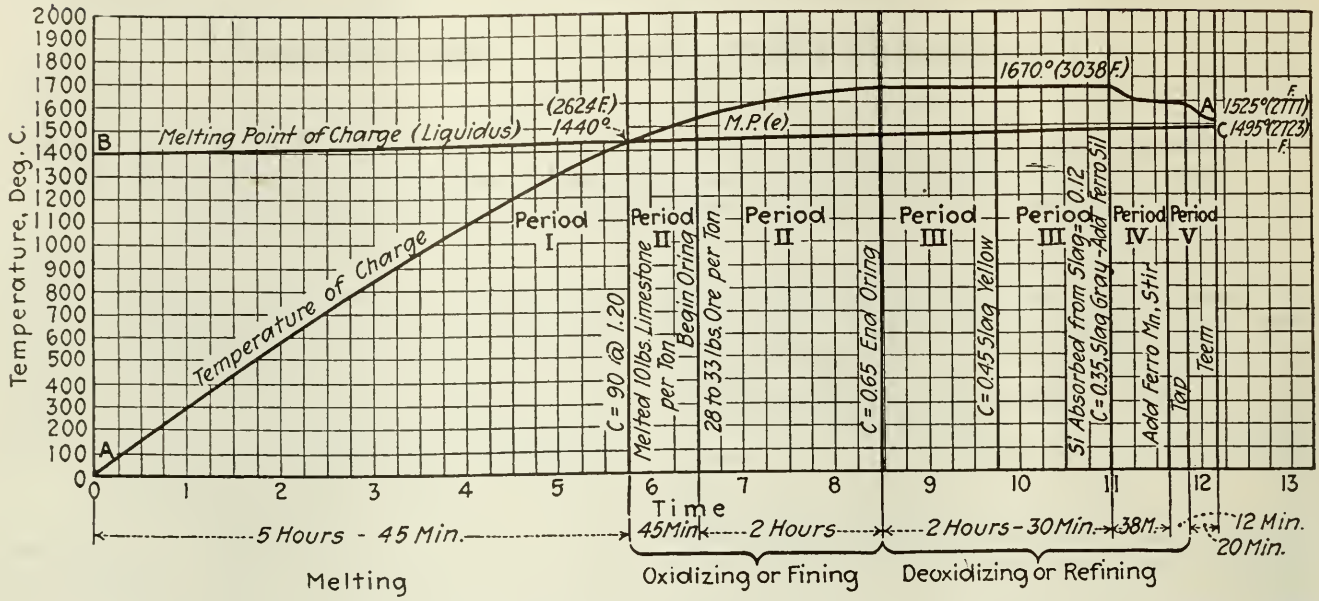

FIG. 1—APPROXIMATION TO A TIME-TEMPERATURE DIAGRAM OF THE ACID OPEN-HEARTH PROCESS ON GUN STEEL

rations for tapping. Further decarburization is halted and deoxidation continued by adding ferrosilicon to the intensely hot bath. This melts quickly, alloys with the metal, and the silicon is rapidly oxidized to silica, which in turn joins with additional basic oxides to form fusible silicates. In a hot bath the resulting silicate particles coalesce, rapidly rise and enter the slag. (It is evident that nearly but not quite enough ferrosilicon should be added to complete the oxidation. If an excess were used, infusible silica inclusions would remain in the finished steel.) Activity of the carbon is further reduced by lowering the temperature by shutting off gas and air and closing the stack damper. Cool areas will quickly show darkly on the quiet slag surface. At this time—the close of period IV of Fig. 1—equilibrium has apparently been reached, and very little change will be noted in the chemical composition of the metal if held in the furnace for many minutes.

Within 40 minutes after the silicon is added ferromanganese is added and stirred in. The bath may possibly contain 0.10 per cent manganese; if 0.73 per cent is added, the resulting ingot will contain about 0.65 per cent Mn, conforming to specification. An apparent loss of not more than one-tenth the addition is an excellent indication that deoxidation has previously been well done. Larger losses in heats which are apparently normal are associated with uncertain metal which should be watched with great care. (Segregates of manganese silicate would doubtless be found in the axial region of the ingot; owing to its fusibility it would remain liquid to the last, and would have a correspondingly enhanced opportunity to coalesce into sizable particles.)

After 12 minutes the diffusion of manganese should be complete. Slag is gray or greenish gray, and the metal is tapped from the furnace to the ladle, held about 20 minutes, when the temperature will be close to the liquidus and proper to pour into very large ingots. Use of aluminum, titanium or vanadium, not as alloying elements but as final deoxidizers or scavengers, should be avoided, since their efficacy will be a direct measure of the temptation to use them to cover up careless furnace practice. They form infusible oxides which remain included in the steel.

It should be apparent that in acid bottoms silicon should be used before manganese. If the latter were added first, it would form basic oxides with the oxygen in the metal, and these would take silica from the hearth to form a fusible slag. Much more alloy would be used, much more damage done to the furnace and much more slag would have to be eliminated from the metal. The arguments and procedure are evidently reversed for basic practice.

Summary[2]

(1) "The steel should be brought at the moment of teeming to the desired composition in every respect.

"The manganese and silicon must be brought to the desired proportion. In order to do this, the bath should be freed from oxygen as nearly as possible and certainly to a constant degree. This freedom from oxygen is important also for lessening or preventing segregation, blow-holes and structural metallurgical weakness.

"Phosphorus and sulphur must be below the prescribed limit, and to this end the stock must be sufficiently free from them.

"The chromium and nickel must be within the prescribed limits.

(2) "The temperature must be accurately regulated.

(3) "Retention of inclusions must be restrained by deoxidizing the molten steel as fully as possible by means of the carbon of the pig iron, because the product of its oxidation is gaseous and escapes, whereas those of all other deoxidizing agents are solid or molten and tend to remain as inclusions. In order that as much as possible of the deoxidation should be done by carbon, the working temperature during refining must be held as high as the safety of the roof will permit.

(4) "The nearly complete deoxidation by carbon should be followed by further deoxidation by silicon. The manganese should not be added till after this silicon has done its work of deoxidation, in order that as little as possible of it may oxidize. This is both so that the manganese content of the product may be as nearly constant as possible, and that as little manganese oxide as possible may form to corrode the siliceous hearth of the furnace and form inclusions of manganese silicate with the silica so eaten away. This postponement clearly tends to lessen the oxidation of manganese;

[2] In the words of the authors.

first, by shortening its stay in the furnace and, second, by pre-deoxidizing the bath with the silicon.

(5) "The steel should be held in the ladle a moderate length of time to allow the inclusions to rise to the surface, and also for the much more important purpose of permitting the finished steel to fall to the proper temperature for casting into a successful ingot.

(6) "The furnace itself must be protected. To that end its hearth should be protected from iron oxide by covering it, before charging the scrap, with about half of the pig iron used.

"The working temperature of the furnace must be maintained during the melting and refining periods at the highest point consistent with safety to the furnace: First, so as to shorten the melting period, during which the hearth is exposed to the attack of the iron oxide, because it is not fully covered by the molten charge; second, so as to stimulate the deoxidizing action of the carbon of the bath during the refining period.

(7) "In all respects the working conditions should be brought as nearly as possible to a fixed standard, because it is difficult to compensate for the results of even minor variations in procedure."

Comparison With European Practice

Typical French and Italian practice uses much less pig iron in the original charge, so that when melted the metal has but 0.10 to 0.20 more carbon than desired in the finished steel. Oring is therefore unnecessary, and period II of Fig. 1 is omitted; refining the bath of oxygen acquired during melting proceeds immediately by reaction with the surplus carbon. If carbon reaches specification before the bath is deoxidized, more carbon is added by periodically adding pig iron, coke or both until the desired condition is arrived at. In some works coke is made to float on a deoxidizing slag, specially made up by additions of lime, clay, sand and fluorspar, until the slag test is green and reactions in the bath cease. Even after this the charge is held for 1 hour at a very high temperature to permit the inclusions to rise and deoxidation to be completed.

Oring allows the use of a larger amount of pig iron, which may be not only more readily accessible than high-quality scrap, but also cheaper. However, it increases the time and correspondingly the fuel bill per ton of product.

Boiling or chemical stirring is a valuable aid in keeping the metal hot enough without destroying the furnace. It is fortunate that the boil is present in a metallurgical practice which produces a heavy blanket or slag, when a maximum of stirring is necessary.

Oring also furnishes some iron and thus increases the yield, but this is not a valid consideration in the manufacture of fine steel.

On the other hand, high pig charges cause thick slag blankets and a correspondingly large amount of material to deoxidize before the metal is quiet. Furthermore pig iron can be refined only by oring, which introduces oxide into the metal, the very thing we are later at such pains to eliminate completely.

It should be remembered, however, that even the act of melting heavy scrap in an open-hearth furnace will oxidize the metal so that refining is necessary; furthermore, that it is the last stage of purification which requires the highest skill—a stage which cannot be avoided in either practice. Even though Americans judge the progress of deoxidation in the metal by the slag appearance, deoxidation is actually done by reaction of carbon and iron oxide *in the metal*, and this is later reflected by a diminished content of iron oxide in the slag. Slag, therefore, is always a step behind the metal, and a satisfactory slag test is proof that the metal has been in good shape for some time. This is an advantage much stressed by American metallurgists. They point out that when the slag is also being deoxidized by coke, its condition is not indicative of the reactions which are going on underneath, even though these reactions may proceed to completion more rapidly.

Physical properties of steels from comparative heats, where the only variable was the presence or absence of the oring stage, are not available for use as an indication of the relative weight which should be given the above considerations.

U. S. Production of Refined Primary Lead in 1921 Compared With Preceding Years

An estimate of the production of lead in the United States during 1921 made by the U. S. Geological Survey is given below, in comparison with figures for preceding years:

	1919 (Short Tons)	1920 (Short Tons)	1921 (Short Tons)
Domestic desilverized lead	208,751	220,327	187,962
Domestic soft lead	147,744	189,854	157,513
Domestic desilverized soft lead	67,938	66,668	52,747
	424,433	476,849	398,222
Foreign desilverized lead	57,787	52,808	50,367
Total refined primary lead	482,220	529,657	448,589
Antimonial lead	13,874	12,535	10,064
APPARENT CONSUMPTION OF REFINED PRIMARY LEAD IN THE UNITED STATES — (REFINERY STOCKS DISREGARDED)			
Supply:			
Stock in bonded warehouse Jan 1	472	234	1,322
Imports of pigs, bars, and old	5,107	35,719	31,301
Production	482,220	529,657	448,589
	487,799	565,610	481,212
Withdrawals:			
Exports of foreign lead—			
From warehouse	40,976	17,363	25,000
In manufactures, with benefit of drawback	1,936	6,175	9,369
Exports of domestic lead	10,510	2,730	1,624
Stock in bonded warehouse Dec. 31	234	1,322	347
	53,656	27,590	36,340
Apparent consumption	434,143	538,020	444,872
Lead content of ore and bullion in bonded warehouse Dec. 31*	45,476	51,220	19,186
Average selling price in cents per pound	5.3	8.0	4.5

*Some part of this may have been smelted and refined and thus be included in the quantities given above as "Foreign desilverized lead."

Tanning Sole Leather With Sulphite Liquor Investigated by Bureau of Standards

The investigation of the durability of sole leather filled with sulphite cellulose extract as compared with sole leather filled with ordinary vegetable tanning materials has been completed and will appear shortly as a technologic paper of the Bureau of Standards.

The results show that sulphite cellulose extract is as firmly fixed in the leather as the ordinary vegetable tanning material and that leather filled with it is as durable as leather filled with such materials as chestnut and quebracho.

Occupational Figures for Chemical Industries

Chemical industries employed 74,289 persons as laborers when the 1920 census was taken. This compares with 41,741, the figure shown in the 1910 census. Semi-skilled operatives totaled 50,341 in 1920 and 30,705 in 1910.

Chemists, assayers and metallurgists, engaged in the practice of their profession, in 1920 numbered 32,941. This compares with 16,273 in 1910.

Metallic Sodium—II

A Critical Review of the Processes Which Have Been Developed for the Preparation of Metallic Sodium by Chemical Reduction—Difficulties Encountered — Chronologically Arranged Bibliography Covering the Metallic Sodium Industry*

By HOWARD E. BATSFORD

FROM the earliest times there have been attempts made to get metallic sodium from its salts by chemical reduction. The basic principle in all these experiments was that of reduction by some form of carbon at a temperature high enough for fusion of the salt and volatilization of the metallic sodium. The sodium was then condensed in a suitable manner.

In 1879 W. P. Thompson mentioned a process in which molten iron alone or in combination with hydrogen or coke was the reducing agent. Iron, mixed with a great deal of coke, was heated in a sort of bessemer converter with caustic soda; and the sodium formed was distilled off.

In 1883 C. A. Faure patented a process for making sodium by reduction of Na_2CO_3. He used a furnace composed of a refractory material, such as compressed magnesia. Electrical conductors were imbedded in the bottom for heating the contents, and holes were left in the top for supply of material and escape of gas and the vapor of sodium.

In 1884 S. G. Thomas used wrought- or cast-iron retorts or tubes with thick lining of refractory material unacted on by sodium. The mixture of Na_2CO_3 and carbon was fed continuously in the current of hot reducing gas. The sodium vapor was condensed from the gases.

In 1886 Dr. E. C. Kleiner-Fiertz reduced the sodium salts by fusing in an arc between two electrodes in a carbon-lined retort.

C. S. Bradley and F. B. Crocker reduced sodium by heating a charge of Na_2CO_3, charcoal and chalk in a hollow cylinder of wrought iron heated by passing a current through it.

St. Clair Deville made a mixture of the following proportions for the reduction: Na_2CO_3, 30 kg.; coal, 13 kg.; chalk, 5 kg.

The chalk has no chemical effect on the reaction, but it is added only to make the mass tacky and not fluid.

All materials were pulverized and screened, then mixed and again passed through a screen, after which they were heated to a red heat in an iron crucible, sintered strongly together and finally converted to a pasty consistency. They were removed from the crucible and transformed into a coarse powder on cooling, the last-named being put into the reduction vessel.

He used as pure soda ash as possible, since the ordinary calcined soda of commerce always gave poor results, containing foreign salts which raised the melting point.

In 1887 J. B. Thompson and W. White invented a process for intimately mixing dry Na_2CO_3 with a liquid carbonaceous material, preferably tar; it was then heated to a dull red heat in iron pots by the waste heat of flue gases. When all volatile matter was consumed, the charge was distilled in a fireclay tubular retort, connected with a tightly closed receiver, containing paraffine oil to insure a non-oxidizing atmosphere and also provided with an escape pipe for CO_2.

O. M. Thowless improved previous methods of sodium production by introducing the NaOH or other compound preheated into the previously heated carbonaceous matter.

In 1888 several patents were issued, as the metal sodium was beginning to be studied very seriously.

H. S. Blackmore heated the following mixture to dull redness for 20 minutes and then to a white heat:

27.5 parts of $Ca(OH)_2$	30.9 parts of dry Na_2CO_3
31.1 parts of Fe_2O_3	10.5 parts of charcoal

Caustic soda was first produced, and the organic matter reduced the ferric oxide to metallic iron, which in turn reduced the soda; the metallic sodium distilled off and was suitably condensed. After slaking, the residue of ferric oxide and quicklime was used again.

A. B. Cunningham fused caustic soda in an open vessel and mixed pulverized carbon with it. He introduced the charge while still liquid into a red-hot retort. The fumes of sodium were condensed.

C. A. Jarvis proposed the use of fireclay apparatus in order to prevent the large amount of corrosion which takes place when iron crucibles or tubes are used.

Netto Process

C. Netto heated a column of coke or charcoal in a retort or receiver to a high temperature. The NaOH was fused and run in, falling as a spray on the red-hot charcoal. It was decomposed very rapidly and the vapors of sodium were able to escape freely between the lumps of charcoal into the receiver.

He further improved his process by continuously feeding fused NaOH into the top of a furnace with a condenser at the top and with a hydraulic trap at the base. The retort was filled about one-half with incandescent charcoal. The sodium distilled over and the Na_2CO_3 produced ran down to the bottom of the retort where it could be siphoned off continuously or intermittently, and thus be prevented from interfering with the continuous action of the process. Sodium by this means could be produced at a much lower temperature and more regularly than when the carbonate was not removed.

H. W. Wallis powdered "hydrated alkali" and mixed it with 10 or 15 per cent of carbonaceous material, which was also pulverized. This mixture he fed at intervals into a heated retort.

In 1889 W. G. Forster introduced coal gas or carbonaceous vapor or other reducing gas or vapors

*For Part I see Chem. & Met. Eng., vol. 26, No. 19, p. 888, May 10, 1922.

Note: Complete references to all the work discussed will be found in the chronologically arranged bibliography at the end of the article.

through a perforated pipe immersed in the fused alkali, distilled the sodium over and condensed it.

T. Parker and A. E. Robinson mixed carbonates, hydrates or oxides of sodium with a quantity of finely divided carbon sufficient to reduce them to the metallic state and heated them by means of "an electric arc or electrical resistance," the metal volatilizing and being condensed. The electrodes used could be of iron, and a liquid bath of iron or other metal might be maintained at the base of the furnace for heat diffusion. The charge was heated before entrance to economize current.

In 1890 the work on the electrolytic production of sodium was given an impetus by Grabau, and during the next ten years little was apparently done on chemical reduction.

In 1899 C. Wolfram introduced a process for reacting calcium carbide with molten caustic soda. He obtained Na_2CO_3 and sodium. By melting salt and introducing carbide he was able to get particles of sodium to come up and float on the bath.

In 1903 T. Parker mixed aluminate of soda with carbon in suitable proportions and calcined them in an electric furnace. Sodium distilled off and alumina was left. In his proposals he also mentioned the use of silicates, from which carborundum was recovered as a secondary product.

During the same year H. Specketer and C. H. Weber invented a process for making sodium by subjecting sodium fluoride to the action of metallic aluminum, having the salt just above the melting point.

Mehner Process

The electrolytic processes of Castner, Darling, Ashcroft, Carrier and others dominated the field and there was little mentioned in literature about chemical reduction till 1912, when H. Mehner proposed to react soda with molten cast iron in such a manner that the sodium metal was set free in vapor form and carbon monoxide was formed. The carbon was returned to the iron by known methods, or the old iron was removed and replaced by new. The reaction was highly endothermic, and the highly heated mass of cast iron was efficacious in furnishing both carbon and extra heat.

In 1913 Swann and Kendall distilled Na_2CO_3 and carbon and conducted the sodium vapor through fused NaOH to condense it from its admixture with CO.

In 1919 H. Freeman proposed to make sodium by treating salt with calcium carbide in a manner slightly different than Wolfram. The present process consisted in mixing the finely powdered substances and heating them to a bright red temperature, not higher than 1,400 deg. C.

The great troubles with the early processes seemed to lie in the difficulty of getting apparatus which would stand the action of the sodium at the high operating temperatures, and also the difficulty in getting the sodium vapor removed from the reduction vessel and condensed. From the author's experience with sodium distillation it seems highly probable that quantities of salt and other impurities were entrained with the sodium vapor and remained to contaminate the finished product.

With the gradually increasing cost of electrical power and labor it seems possible that some chemical reduction method may be able to compete successfully with the electrolytic ones. Men are now working on this problem, as is evidenced by the patents coming out from time to time, and also by the fact that sodium may be used for several of the intermediate manufacturing processes, as well as for making peroxide bleach and sodium cyanide.

The Technical Man as a Citizen*

By Acheson Smith

NEVER in the history of our country has there been such a pressing need for an intelligent citizenry. The post-war problems are of such a nature that it is difficult to understand them and consequently almost impossible correctly to solve them. Various solutions are offered for the same problem, and to the great mass of people, unfamiliar with the technical side of a question, a man with an unsound penacea will appear to be just as safe to follow as the man who is a real authority on the subject.

The tendency is to look to our government for aid, and as governmental aid is usually legislative, all kinds of legislation are proposed or enacted. In the opinion of many our revenue laws can be made to contribute to the prosperity of the country, but their provisions always provoke controversy and the final enactment is usually a geographical and personal compromise. Our financial system is constantly subject to attack and there is an effort being made at present to alter it so as to make money more plentiful. Laws relating to our agricultural, mineral, water-power and other natural resources should be drawn with the greatest care, for upon their wise development will depend much of the future wealth of the nation. Regulatory legislation is being urged more and more, and while its purpose may be very laudable, the carrying out of such laws requires so many enforcement officers that we are adding a burden to ourselves which has a doubly bad effect. First, it requires the expenditure of a great deal of money to enforce such regulation, and secondly, it takes a large number of people who might be producers and places them squarely in the unproductive, official class.

Country Confronted by Serious Problems

Many other serious problems are before the country and the world today. For instance, the supremacy of the white race is being challenged by those whose color is black or yellow, and the white race can maintain its position only by raising the intelligence of its leadership.

It is perhaps natural, under our form of government, for the proletariat to put great faith in political laws and to be blissfully ignorant of the fact that where such laws are not based upon sound economic principles they will sooner or later prove futile. The futility of political laws when they are contrary to the economic needs is well illustrated by the conditions now prevalent throughout eastern Europe. Much more could be said on this subject, but it will probably suffice to add that the future success and safety of our country will depend upon the intelligence of its leaders.

When Lord Macaulay wrote his famous letter in which he expressed doubt about the ultimate success of Jeffersonian democracy, he said that "such democracy would sooner or later destroy liberty." We are now evidently in the process of being tried to see if this republic can endure. It is comparatively safe from external enemies, but if we do not act wisely and in conformity to sound economic law we may be destroyed by our own acts, in spite of our good intentions. The times, therefore, call for strong men; men who have knowledge, men who have been taught to reason and to be guided by fact. This type of man being demanded, none are better able to qualify than chemists, engineers and other technical men.

"The Age of the Engineer"

We often hear the statement that this is the age of the engineer, but it is possible that we do not understand the full significance of that phrase. The present advanced state of civilization is mainly due to the technical men. That we have more comforts and luxuries today than we could have had a hundred years ago, and at the same time have more leisure for study and recreation, is due to the greater productivity per man, due to labor-saving devices, improved processes and administrative methods. If production per capita had not increased, we would have little time for the fine arts, and no means with which to sustain those who would devote their lives to such pursuits. If we desire to visualize what the world owes to the technical man, all we have to do is to consider what would happen if our steam and electric power and all machinery and modern chemistry were taken away from us. We would have to reorganize society, and each one would be so occupied in producing the necessities of life he would have no time to produce non-essentials, and very little if any time to enjoy them.

The present standard of living among our laboring people is solely due to the engineer. For example: If a farmer is able to produce only enough to feed and clothe his family, he has no time for the finer things of life and cannot afford any luxuries. If, however, he can produce twice as much as is necessary to feed and clothe his family, he will have a surplus with which he can purchase luxuries. The number of luxuries he can buy will depend upon their cost, and therefore the cheaper they can be produced the more he can purchase. We thus see that the greater productiveness of the farmer enables him to acquire luxuries, and the greater the productiveness of those who manufacture them the cheaper these will be, and therefore the more the farmer can purchase. As the ability of the farmer and manufacturer to produce is largely dependent upon the implements and methods supplied by the engineer, we can see that upon him rests the responsibility for future progress and the credit for what has already been accomplished.

Increased Production Raises Living Standard

Putting it another way: The greater our productiveness the fewer people it will require to produce the necessities of life, and therefore the greater number that can be spared to work in art, medicine and other pursuits that contribute so definitely to our pleasures and comforts. In fact, our present standard of living can be maintained only if we keep up our production, and it is certain that the standard of living cannot be raised unless we increase our production per capita. As our increased production is due to the technical men, we see that the whole material progress of the country depends upon progress in pure and applied science.

If the things that make life worth while are ours because of greater productivity, it follows that we should honor the producers and do everything we can to educate all to the necessity for producing beyond their needs. The greatest incentive so far discovered to induce people to produce beyond their immediate

*Presidential address delivered before the American Electrochemical Society, at the forty-first general meeting, Baltimore, April 27-29, 1922.

Note: The terms engineer, chemist, technical men, etc., are used synonymously, and are meant to include all men working in pure and applied science.

requirements is the principle of property rights. When a man knows he can enjoy the products of his labor he will produce beyond the needs of the day, but if he is in doubt about being protected in such a right he will be without the incentive to produce a surplus. Therefore, we, as men who understand the tremendously serious effect of withdrawing or endangering such right to the enjoyment of property, should guard it zealously as the bedrock of civilization. While it sounds rather utilitarian to preach the gospel of production and property rights, it should be remembered that culture and the finer things of life presuppose leisure, and the amount of leisure we possess is in direct relation to the surplus of life's necessities which are produced per man.

The Engineer Seeking Recognition

In view of what has been accomplished by the engineer it may sound strange to say that he is seeking recognition, but such is the case. Nearly every technical society has had meetings and papers on such subjects as the status of the engineer. Practically all of the technical publications have had articles lamenting that the technical man does not take his proper place as a citizen and is not found in our legislative bodies. Comparatively recently a Federation of Engineering Societies was formed for the purpose of increasing their influence at Washington. Many articles could be cited wherein it is pointed out that the engineer should have greater recognition, and suggesting ways by which that very desirable end could be attained. It is evident that among the technical men of the country there is a feeling that they do not occupy as influential a position as they should.

If technical men are the leaders in science and industry, and no one will dispute that they are, and if they seek recognition, it must be in civic and political fields. The question, therefore, arises, What can the engineer do to procure such recognition? The matter has been discussed at considerable length, and the engineer should now take definite action toward attaining the position he seeks.

If we distinguish between the effort to force recognition through strength of numbers and the recognition gained by the profession through its individual members becoming influential, we shall see that recognition of a group or class is difficult to procure and more difficult to maintain, while recognition of individuals is a natural force which extends throughout our whole political system. It is not desirable that engineers exercise influence as a class, but that they as individuals gain a position of influence. The first would be artificial and uneconomic, while the latter would be very desirable and perfectly sound, because the struggle for success as individuals builds character, while the success of a class does not.

If we examine the political organization of our country, we shall find that overlapping spheres of influence exist, reaching from the humblest community to the highest official circles in Washington. An individual becomes active in the political and civic affairs of his own locality and is brought into contact with other similar individuals, who together form the dominating group in the city. A few from each city make the controlling group throughout the state, and a group from the various states are the influential men in the nation. These men are the real leaders and those who would take an active part in our body politic must be willing to work as these men are working. We must realize that the political machinery which controls our government is an actual fact, and if we are to become influential in the nation's affairs we must recognize the rules of the game and play accordingly. We, therefore, see that the leaders in the country are those who do a citizen's duty and a little more, over a term of years, and as a result find themselves the influential men in their community. Here is an opportunity for the engineer to do his locality a substantial service and at the same time put himself in a position of real influence in the state and nation.

Under a system of government where the illiterate and men of low ideals have an equal voice with the educated and men of high ideals, the only thing that can prevent liberty from destroying itself is intelligent leadership. The technical men of the country should, therefore, start to work, each in his own community, and see if we cannot in a generation or two raise the standard of leadership so that sound thinking shall become the dominating influence in our legislative bodies.

The engineer is justified in striving for a high degree of technical attainment, but he should not lose sight of the fact that if he does not have the ability to lead he will probably not get very far in his chosen profession nor in the civic field. The qualities of leadership must be developed, and there is probably no better way to begin than by taking a minor part in political affairs, working in civic bodies and taking an active part in at least one technical society. A man who is not willing to give a portion of his time and talents to his technical society has lost sight of the fact that by doing so he will develop himself as well as advance the interests of the profession. It is not what he takes in but what he gives out that constitutes his contribution to the world's work, and unless a man can become constructive he cannot hope for success. By taking an active part in civic affairs he will benefit his home community and at the same time be training himself to be a leader.

Need for Educated Men in Civic Life

While it is quite necessary that a man make himself proficient in his chosen line of work and avoid such things as would seriously interfere with such development, he should remember that this is a government of and by the people, and if he does not do his share someone is doing it for him and probably doing it less ably than he could do it. He might well heed the words of Herbert Spencer: "The man expending his energy wholly on private affairs, refusing to take part in public affairs, pluming himself on his wisdom in minding his own business, is blind to the fact that his own business is made possible only by the prosperity of all."

There is a great need for educated men in all strata of civic and political endeavor, and the university-trained men can render wonderful service if each one will do his part. If a technical man does not gain the position of influence he seeks he either does not have sufficient ability or he is unwilling to do the necessary work. If, however, the engineer will remember that he is a citizen as well as a technical man and develop himself by serving his own locality, he will some day be surprised and pleased to find that his influence extends beyond his community and is perhaps felt throughout the nation. Thus by his personal attainment he will help in procuring deserved recognition for the technical profession.

Recovery and Utilization of Cyanide From Byproduct Coke Ovens

Cyanogen Compounds Available in American Coke-Oven Gas Are Adequate to Supply Our Entire Demands—Description of a Process for the Direct Recovery of Hydrocyanic Acid and Sodium Cyanide—Possible Replacement of NaCN by HCN

By EDWARD V. ESPENHAHN

THE LARGE coke-oven installations in the United States and Europe present a source of supply of cyanide, which so far has not yet been exploited to any appreciable extent. Although the ferrocyanides are obtained by indirect methods from coal-gas works, the simple cyanide salts of the alkali metals are usually produced synthetically. The desirability of removing the hydrocyanic acid from coal gas at such works is generally recognized, but usually the conditions are not favorable for this recovery primarily because of the relatively high installation and operating costs. These disadvantages, however, do not exist at coke-oven plants, or at least to such an important extent, since much larger quantities of coal are carbonized at these plants and overhead expenses are correspondingly low.

The failure to recover cyanide at coke ovens at the present time may be attributed to the indirect methods hitherto adopted, and it is the opinion of the author that should these sources be exploited economically direct recovery methods must be resorted to. When coal began to be coked on a large scale in byproduct ovens, it was early recognized by coking technologists that the indirect methods of ammonium-sulphate recovery, whereby the ammonia of the gases is first absorbed by scrubbing with water, from which it is distilled by steam before being reabsorbed in sulphuric acid, were no longer suited for large-scale operation. The direct processes were then devised and have been almost universally adopted for the recovery of ammonium sulphate. The gas is passed directly through a bath of a saturated ammonium sulphate solution, which is kept slightly acid, between 50 and 80 deg. C., from which the precipitated salt is removed and washed by mechanical means. About the only instances where indirect processes are still employed is where a good market is obtainable for liquid ammonia, such as in the ammonia-soda process. Should cyanide recovery eventually be adopted at coke-oven plants, it might be expected to follow this history of ammonia recovery, wherein indirect methods hitherto used were discarded and superseded by direct and economical processes.

It is the purpose of the present article to describe such a process for the direct recovery of cyanogen compounds from coke-oven gas, but before such a description is attempted, it is believed that a brief review of the consumption and uses of cyanides will be of interest.

Consumption of Cyanides

The cyanide and ferrocyanide or prussiate salts of the alkali metals are among the most important inorganic chemicals used in the industrial arts. The consumption of the former in this country amounts to tonnages represented by five figures and the consumption of the ferrocyanides is somewhat less than half that of the simple cyanides. Statistics compiled prior to 1914 do not permit a survey of the separate sources of the cyanide salts, but in that year the imports and domestic manufacture amounted to 12,000 tons; in addition 3,250 tons of potassium ferrocyanide was consumed.[1] These tonnages from foreign and domestic sources were about evenly distributed. In 1919 about 11,000 tons NaCN was consumed, 25 per cent of which was imported. The consumption of sodium ferrocyanide was over 4,000 tons, of which 15 per cent was obtained from foreign countries.

Mexico is also one of the largest consumers of cyanide, where it is used mostly in treating silver ores. Practically all of the salt is imported from Europe, and the total Mexican consumption may be estimated to be at least 3,500 tons and perhaps may amount to 5,000 tons. Furthermore, at least 1,200 tons is used in Canada yearly.

Owing to abnormal business conditions, there was a decrease in the consumption of cyanide during 1920 and 1921, so that the year 1919 probably represents the best index of future requirements. It is rather remarkable, however, that the consumption has been maintained to such an extent while gold mining was at such a low ebb, although silver mining remained fairly steady. These indications point to the fact that other important and equally extensive uses have been found for this chemical. With prospects of the price being reduced to the pre-war level, a further impetus will be given for its consumption, especially along new avenues, which will be discussed in the following paragraphs.

Uses of Cyanide

Sodium cyanide and potassium cyanide, or mixtures of the two salts, are used principally for (1) extraction of gold and silver from ores; (2) generation of HCN for fumigation of fruit trees and eradication of rats and other vermin; (3) case-hardening of steel; (4) electroplating; and (5) miscellaneous uses, such as in the synthesis of dyes and other organic chemicals.

Comparing the first two uses, it does not seem improbable but that the importance of the chemical in gold mining has been relegated to an inferior position by the increased demand of cyanide by horticulture. The use of HCN for fumigating citrus trees is now firmly established in California, and although only one-third of the 20,000,000 trees in bearing are treated, it is claimed that from this third the bulk of the crop is obtained. The treatment provides the only effective means of

[1]For detailed information see official publications: U. S. Dept. of Commerce Bulletin 82, "Imports of Chemicals in 1914"; U. S. Tariff Commission, Tariff Information Surveys on "Sodium Compounds"; and U. S. Geological Survey Bulletins "Sodium and Sodium Salts."

overcoming pests harmful to the crop, so that it is to be expected that the benefits arising from fumigation will also become recognized by the citrus-growing areas of the South American states, especially since a moist climate is more conducive to the growth of pests and fungi.

About 500 tons of NaCN is consumed annually by the Department of Agriculture in fumigating freight cars at the Mexican border to keep out the pink boll weevil.

Case-hardening and electroplating annually require considerable quantities of cyanides. In the latter industry it is not unlikely that the electroplating of sheet iron will to a great extent displace galvanizing by hot dipping. The developments of the electrolytic zinc industry permit the use of the commercial article in new ways, and considerable investigation is now being conducted on the electrodeposition of zinc from sodium-zinc cyanide solutions. The coating thus obtained has a greater protective action against rusting than one from sulphate solutions.[2]

Under favorable conditions regarding cost of production, sodium cyanide might be considered as one means for conducting the synthesis of indigo. As it is, however, only relatively small quantities are used in the manufacture of dyes and synthetic organic chemicals.

Replacement of Sodium Cyanide by Hydrocyanic Acid

Hydrocyanic acid gas has already displaced the solid salt used in the old "pot method" of fumigation. This method was both dangerous and inefficient, and recently Harker[3] has shown that only about one-third of the HCN of the salt is liberated when sodium cyanide and sulphuric acid react on each other under ordinary conditions. The other two-thirds is therefore lost for fumigating purposes.

The use of hydrocyanic acid gas is now firmly established in California. The gas is generated in stations close to the fruit-growing areas, so that should the gas from coke ovens be used it would have to be transported over longer distances. Although certain restrictions are placed on the transportation of this gas, they are not sufficient to offset the advantages of having the cyanide in the most concentrated form possible, as 1 lb. of the gas is equal to at least 2 lb. or as much as 4 lb. of the less pure commercial salt. It cannot be denied that in the handling of hydrocyanic acid there is a certain amount of danger, but the few accidents resulting from the handling of such large quantities of the gas in California attest its comparative safety when due precautions are taken. Compressed in cylinders, it is probably as safe as any other toxic gas.

Apparently there is no reason why the use of hydrocyanide acid gas should not be extended, and made to replace sodium cyanide in other uses; provided it is possible to produce the cyanide more economically in the form of the gas. Thus in ore treating, calcium cyanide might be prepared easily and cheaply at the mines by passing a weighed amount of HCN gas from cylinders into a tank of water containing a slight excess of lime in solution. Calcium cyanide is readily formed and is quite stable in the dilutions employed for extracting gold and silver from ores. In some instances it might be necessary to add a corresponding amount of soda ash to form the sodium compound. This then would be produced without first obtaining the solid salt, thus saving the evaporation and other costs in preparing the ordinary commercial product.

In a like manner the preparation and purification of cyanide electrolytic solutions by means of a zinc salt and hydrocyanic acid gas, lime and soda ash instead of sodium cyanide is also suggested. The preparation of zinc cyanide could proceed from calcium cyanide as favorably as from sodium cyanide. When the latter salt only is desired, the double reaction between HCN, lime and soda ash would be resorted to. It could also be applied for rejuvenating cyanide solutions which have become impoverished in cyanide by the absorption of CO_2. In this instance, of course, no soda ash would be required; the calcium cyanide would be added direct, and the purified solution returned to the cells after filtering off the calcium carbonate, which is easily washed.

Description of Espenhahn Process

The process previously referred to for the direct recovery of cyanogen compounds from coke-oven gas has been described in the British patent 109,254 (1916), in U. S. patent 15,090 (1921 reissue) and in a number of foreign patents. It is designed to operate in conjunction with direct and semi-direct methods of ammonia recovery. Briefly, the washing solution consists of a strong solution of an alkali, such as soda ash, in which is suspended an iron compound, such as ferrous sulphide or sodium ferrous-ferrocyanide, which is capable with combining with the HCN of the gas. The iron compound is not withdrawn from the cycle of operations, the only chemicals added being soda ash, sulphuric acid and lime. The solution with the iron precipitate in suspension is circulated from tanks over vertical centrifugal washers, through which the gases pass, preferably after having been previously freed of their ammonia. These washers are very efficient in operation, as they bring the gas into intimate contact with the solution without offering large back pressure, require little power and take up only a small space. The hydrocyanic acid present in the gas is absorbed practically quantitatively as sodium ferrocyanide; and no side reactions occur, such as the formation of sulphocyanides. When the solution in the first washing tank has become charged with sodium ferrocyanide—about 75 per cent conversion—it is filtered through leaf filters suspended in the tank. The solubilities of the two salts in solution, sodium carbonate and ferrocyanide, are such that on being cooled after its withdrawal only the latter salt is precipitated. The crystals of ferrocyanide are then centrifuged before being transferred to a still, in which they are heated with the theoretical amount of sulphuric acid to drive off half the hydrocyanic acid and according to the reaction:

$$2Na_4Fe(CN)_6 + 3H_2SO_4 = Na_2FeFe(CN)_6 + 3Na_2SO_4 + 6HCN$$

The precipitate of sodium ferrous-ferrocyanide is washed free from sodium sulphate and transferred to the last washing tank containing the highest percentage of soda ash, from which it is circulated in countercurrent system, meeting the gas in the vertical washers. Here the precipitate is first converted into soluble ferrocyanide and ferrous sulphide by the hydrogen sulphide of the gas, according to the equation:

$$Na_2FeFe(CN)_6 + Na_2CO_3 + H_2S = Na_4Fe(CN)_6 + FeS + H_2O + CO_2$$

The solution of ferrocyanide with the excess soda ash

[2] C. J. Wernlund, *Trans.*, Am. Electrochem. Soc., 1921, pp. 346-366.

[3] *J. Soc. Chem. Ind.*, 1921, pp. 182-185.

finds its way to the last tank, and by being pumped over the first washer becomes enriched in soluble ferrocyanide until it is withdrawn. The solution containing the most soda ash and FeS absorbs the last of the HCN from the gases in the last washer. This washer is divided into two sections, in the upper one of which the FeS precipitate is prepared by circulating a solution of iron sulphate to which ammonia has been added. The section is used for this purpose only when a fresh supply of FeS is required, as for instance when ferrocyanide is withdrawn from the system. At other times the whole washer is devoted to the extraction of cyanide. The description is made clearer by the accompanying flow sheet shown in Fig. 1.

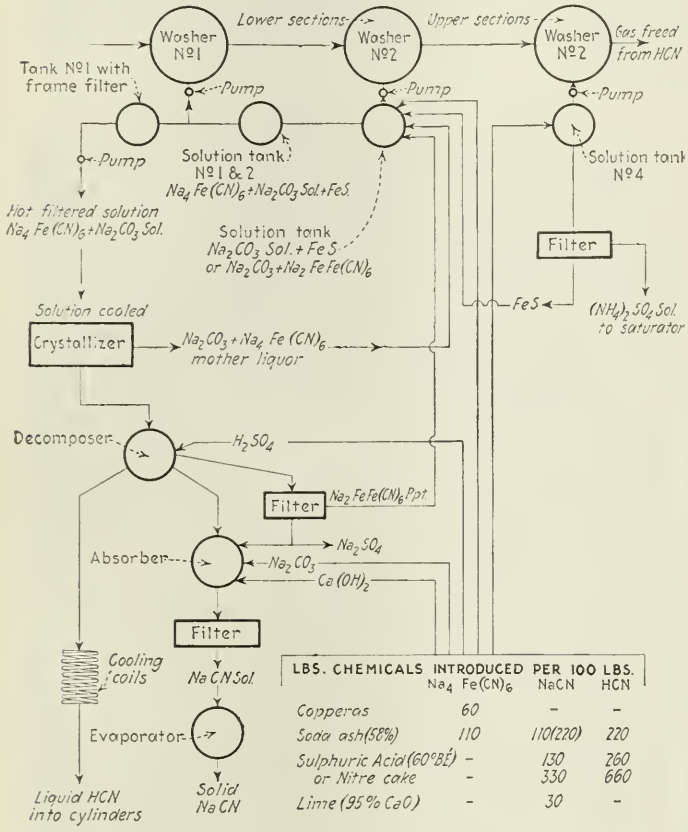

FIG. 1—FLOW SHEET OF PROCESS FOR THE DIRECT RECOVERY OF CYANOGEN PRODUCTS FROM COKE-OVEN GAS

As will be discussed later, the process promises to render the recovery of HCN possible in a very economical manner. If sodium cyanide is desired, it is preferable, owing to the high cost of caustic soda, to proceed with its preparation by absorbing the HCN in a solution of sodium sulphate or carbonate containing an equivalent of slaked lime in suspension. Double decomposition occurs with the formation of sodium cyanide and the precipitation of the lime in the form of the sodium salt employed. If sodium sulphate is used for this purpose, the process is rendered still more cyclic, since less soda ash and sulphuric acid are introduced into the scrubbing process, although in this instance the sodium cyanide recovered will not be as pure as when soda ash is used.

Cyanide Available From Coke Ovens

From several determinations made by the writer at different coke-oven plants in this country, it has been found that the gases contain on an average—the fluctuations are very slight—70 to 75 grains of HCN per 100 cu.ft., so that there is available from a ton of average coking coal at least 1 lb. of hydrocyanic acid or 1.75 lb. of sodium cyanide. Compared with the original quantity of coal charged into the ovens, or even with the yield of tar or ammonium sulphate, this amount at first sight may not appear considerable; but in the aggregate the quantities are more impressive. Thus at a coke-oven installation of moderate capacity carbonizing 2,000 tons of coal a day, there may be recovered 600 tons of sodium cyanide a year. Reviewing the byproducts statistics of this country, it will be seen that the quantity of cyanide now going to waste is considerable, and annually amounts to a tonnage represented by five figures.

Assuming a normal recovery of 1.75 lb. of sodium cyanide per ton of good coking coal, the estimated yield if direct recovery plants were introduced at all works in the near future may be considered to be between 25,000 and 27,000 tons of NaCN. The economical production by a direct process is, however, lower than appears from these figures. It will not be profitable in many instances for units of smaller sizes to install such a process, unless they are favorably situated near points of consumption, such as gold and silver mining centers. Hence the economical capacity of all ovens may be considered to be at most about 20,000 tons per annum,

It might be economical for such plants, however, to introduce recovery of ferrocyanide, as installation and operating costs are considerably lower when producing this compound only. It is also possible to centralize half of the cyclic process, whereby the ferrocyanide from one or more units is converted into hydrocyanic acid or sodium cyanide at a single plant centrally situated. By this means a considerable saving is obtained in operating and installation costs. This method of operation would appear advantageous in Great Britain, where byproduct plants are grouped in different localities, in any one of which the plants are relatively close together. The transportation of ferrocyanide to the central plant would thus not be attended with high freight costs, such as might be the case in the United States.

It is true that some plants have already introduced cyanide recovery, but with these few sodium ferrocyanide is generally the finished product. This is produced in a manner similar to European practice, by first forming a complex ammonium ferrocyanide, which is converted into sodium ferrocyanide at a separate stage after the washing process. The quantity thus produced, however, is very small and in value is negligible compared with any of the other byproducts. At such plants the ammonia of the gas is recovered by indirect methods. Few of the operators using direct recovery, certainly none at the larger units, have attached any importance to the cyanide in their gas, or at least they have not looked upon its recovery as economical.

Cost of Recovery

It is not intended in this paper to present an analysis of the costs of production. With rapid changes in prices of chemicals and materials as well as in labor and construction costs, such a presentation would require too frequent revision to be of much service. It is considered more suitable to make only general comparisons between the pre-war price of sodium cyanide (96 to 98 per cent), which was 15c. a lb., and the estimated cost of production under high post-war conditions, such as existed at

the beginning of 1921. The cost of manufacturing sodium cyanide and hydrocyanic acid from coke-oven gases by the process described in this paper is compared with the cost of producing hydrocyanic acid from synthetic cyanide in the following table:

	Price Per Lb. NaCN	Estimated Cost Per Lb HCN
By synthetic process (in 1913) . .	15c.	30-33c.
By synthetic process (in 1921) . .	20-24c.	37-52c.
By Espenhahn process (in 1921)	4.5-9.0c.	9-13.5c.
HCN as NaCN, per lb. (in 1921)	4.0-5.0c.	. . . . .

From such figures the production of sodium cyanide from coke-oven gases appears decidedly advantageous, but they are still crude estimates, based on a process which has not yet reached a semi-commercial scale.

When coke ovens are considered as a source of HCN instead of NaCN, the comparison is still more favorable to the direct process, especially since, as has already been pointed out, the gas is able to replace the solid salt with advantage in many instances. With synthetic processes it is first necesary to produce sodium salt before being able to proceed with the preparation of the gas; while with a direct recovery process from coke-oven gases the reverse holds true. This means that in the latter process considerably less labor and plant expenditure is required for the recovery of HCN than for NaCN; indeed it is approximately two-thirds. In other words, conditions are more favorable for the production of HCN as a byproduct direct than from an alkali salt, from which it must be liberated, such as is necessary in all synthetic processes now in operation.

Recent Researches on Static Notched Bar Testing

By Herman A. Holz

THE notched bar test is not necessarily an impact test. In fact, the static method of investigating notch brittleness as carried out on the Humfrey machine[1] possesses a number of important advantages:

In the single blow impact test one single figure only is obtained, representing the total energy expended in breaking the specimen plus an unknown and variable amount in friction, vibrations and noise, but no information is available as to the values of the various factors of which this figure is the integral. On the other hand in a static test the forces applied are under perfect control and can be measured with great precision. In breaking a notched specimen in a static testing machine, the angle to which the test piece is bent and the resistance which it offers to the external bending moment are known at each stage of the test. A complete and continuous autographic diagram of the bending-angle bending-moment may be therefore obtained, while the total force expended in fracture may be indicated by an automatic integrator.

Researches on the influence of variations in temperature, depth of notch or radius of notch can be conveniently carried out on the static machine, and a number of check tests can be made on adjoining sections of each specimen.

The curves shown herewith are results of recent experiments undertaken by J. C. W. Humfrey, the British metallurgist who designed the static notched bar testing machine carrying his name.

Fig. 1 shows a number of typical Humfrey curves, the standard specimens being 10 mm. square, with a V-notch 2 mm. deep, angle 45 degrees, radius at bottom $\frac{1}{4}$ mm. (the standard Izod specimen). As will be seen, tough Ni:Cr steel gave the highest value, both in the maximum strength of the specimen—i.e., the resistance to slow bending until the metal back of the notch gave way, and also in the resistance of the material to propagate the crack after initial fracture had once set in. The curve for "temper brittle Ni:Cr steel" runs parallel to that of the same material in tough state, showing a similar resistance to static bend, but shortly before the maximum bending was obtained in the correctly heat-treated material, the temper brittle steel fractures, the fracture running at once across the entire cross-section of the specimen, no resistance whatever being offered to the propagation of the crack after it was once started. The curve for "nickel steel forging" also shows strength and toughness. The next three curves (0.35 carbon steel forging; 0.42 carbon steel normalized, and dead mild steel) are of considerable interest. While the two first-named steels run fairly parallel through a considerable portion of the bending operation, the forged material being slightly stronger in that regard, the normalized steel (0.42 C) is more ductile, the forged specimen breaking clear off at its maximum bend. The "dead mild steel" shows, of course, lower strength but high ductility. The "soft brass" showed the highest ductility, reaching the maximum bending angle at more than twice that of tough Ni:Cr steel (0.425 radians against 0.2 radians). It is very interesting to notice in these typical curves that the plain carbon steels show irregularities in the initial portions of the curves, while

[1] Chem. & Met. Eng., vol. 23, p. 1180, Dec. 15, 1920.

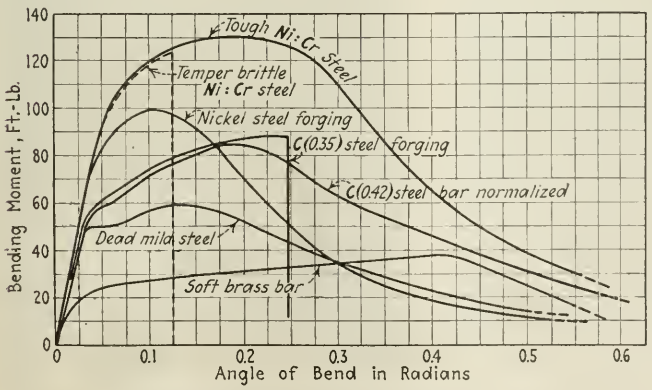

FIG. 1—TYPICAL DIAGRAMS OF VARIOUS ALLOYS, USING THE STANDARD IZOD SPECIMEN

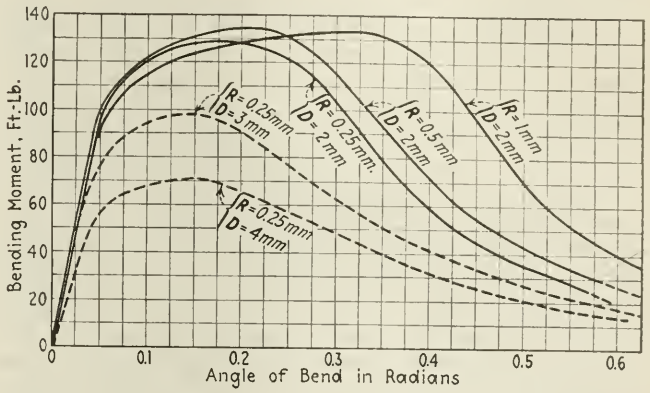

FIG. 2—EFFECT OF VARIATIONS OF RADIUS AT BOTTOM OF NOTCH AND DEPTH OF NOTCH IN TOUGH Ni:Cr STEEL

these do not appear in any of the other alloys investigated. It seems that these irregularities are due to the identical molecular disturbances in these steels which produce the "drop of the beam" in the tensile test.

Fig. 2 shows the effect of variations of radius at bottom of notch in tough Ni:Cr steel. Radii of 0.25 mm., 0.5 mm. and 1 mm. were investigated and the well-known law was confirmed that notched material breaks easier with a sharper notch, on account of the increased concentration of force. In the latter case the curves are almost identical, fracture with $\frac{1}{4}$ mm. radius occurring as shown in Fig. 1; $\frac{1}{2}$ mm. increasing the bending moment at sudden fracture to 125 ft.-lb. and deflection of 0.225 radians. Radius of 1 mm. slightly increases the bending moment, but fracture is resisted until the specimen bends through an angle equal to 0.335 radians (19 deg.). Much the same variations were observed in temper-brittle Ni:Cr steel.

Fig. 2 also demonstrates the effect of variations in the depth of notch; notches of 2 mm., 3 mm. and 4 mm. depth were investigated, the specimen cross-section remaining 10 mm. square, with no variations in the angle or bottom radius of the standard notch.

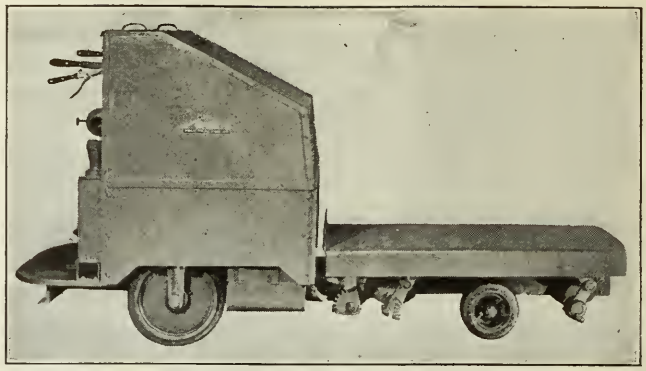
Looking over these curves, it will be readily appreciated that they yield much more valuable information than the single figures obtained in the notched bar impact test. In Fig. 1 the area covered by the curve for brass is more than twice as large as that for temper-brittle Ni:Cr steel. In a single blow impact test the "impact figure" of the brass would, therefore, be more than twice as high than that of the temper-brittle steel, but the interesting story connected with each fracture, demonstrating clearly the values of the factors of which the impact figure is the integral, would be missing. Furthermore, the area covered by the 0.42 carbon steel curve is considerably larger than that covered by the forged nickel steel curve; in this case, the impact figure would have been higher for the 0.42 carbon steel. On the other hand, the forged nickel steel is undoubtedly the stronger of the two materials, possessing a higher resistance against initial fracture at the notch. This point would not be brought out in the impact test, but is clearly shown in the Humfrey diagram. In the construction of machinery it may be preferable in some cases to utilize material of high resistance to initial notch fracture, while in other cases a steel will be found safer which offers a higher resistance to propagation of a crack.

Research work along similar lines will be of great practical value in the metallurgy and heat-treatment of ferrous and non-ferrous alloys. One subject still to be investigated is the reason for the very large increase in notch brittleness of steel at the lower range of atmospheric temperatures (from 0 deg. C. down to —30 deg. C.), resulting in failures of railroad material in winter and of aviation material in high altitudes. Such research work on low temperatures can be conveniently carried out by means of the Humfrey apparatus.

New Gasoline-Powered Lift Truck

The Clark Tructractor Co., of Buchanan, Mich., has placed on the market a gasoline-powered elevating platform truck. This truck is shown in the accompanying illustration. It will be noticed that it conforms in appearance to the electric lift trucks which have been in use for some years past.

The truck has a loading platform 26 x 54 in. which will elevate a load of 4,000 lb. from a minimum of 11 in. to a maximum of 16 in. above the floor in 8 seconds. This lift can be stopped by a hand control lever at any point. There are automatic stops for both upper and lower limits. The lifting mechanism is operated by hydraulic pressure.



GASOLINE-POWERED ELEVATING PLATFORM TRUCK

The power plant consists of a 15-hp. four-cylinder tractor engine of $3\frac{1}{8}$-in. bore and $4\frac{1}{2}$-in. stroke. Engine, transmission, governor, fuel tank and radiator are mounted together in a closed compartment. The drive is through a bevel geared axle. The design of all the parts is such that any good automobile mechanic can do all necessary maintenance.

The advantage of this machine lies in the use of a gasoline power plant. This permits continuous operation without the stops for changing battery necessary where storage batteries are used. Full power is available at all times. For plants located so that a charging station cannot be conveniently installed, the application of this truck should solve many difficulties.

Synopsis of Recent Chemical & Metallurgical Literature

Comparison of Expelled and Extracted Corn Oils.*— Comparison is made of the general characters and quality of three types of corn oil which have been prepared from the same general lot of material so as to make their source comparable. The three types are as follows: (1) Oil produced by expellers at the plant, (2) oil extracted with benzene from germs from the same source, and (3) oil extracted with benzene from the oil cake obtained from

TABLE I—COLOR AND APPEARANCE OF CRUDE CORN OIL IN STANDARD 5½-INCH BOTTLES AFTER STANDING IN THE DARK FOR ONE MONTH

Oils (*a*)	Color	Clarity, Deposit of Solids, etc
Sample D, dry-process germ by expeller	Bright golden	Very slight whitish deposit
Sample E, dry-process germ by solvent	Bright golden	About ¼-in. whitish deposit
Sample A, wet-process germ by expeller	Bright golden, with reddish tinge	Very slight whitish deposit
Sample B, wet-process germ by solvent	Slightly more reddish than oil A	About ⅛-in. whitish deposit
Sample F, dry-process oil cake by solvent	Reddish yellow	¾-in. dark brown deposit
Sample C, wet-process oil cake by solvent	Reddish brown	½-in. light brown deposit

(*a*) The samples of oil are arranged according to their depth of color, lightest to darkest.

*Abstract of Bulletin 1054, by A. F. Sievers, issued by the Department of Agriculture, Bureau of Plant Industry, March 11, 1922.

TABLE II—COMPARISON OF SOME PHYSICAL AND CHEMICAL CONSTANTS OF THE FINISHED CORN OILS

the first-mentioned process. These oils were neutralized, bleached and deodorized, their physical and chemical constants determined, and their color, odor and taste compared. Such a comparison should show whether there is a possibility of preparing corn oil by benzene extraction that will be equal to that produced by the expeller method.

Samples of the two expeller oils and the four benzene-extracted oils were placed in standard 5¼-in. bottles for the purpose of comparing the color and other characteristics. Some of the oils, especially the benzene-extracted oils from the oil cake, appeared to be somewhat turbid when cold, although they were filtered clear while warm. For this reason the samples were permitted to stand in a dark place for a month and their condition then noted. Table I summarizes the appearance of the oils.

Of the crude oils those extracted from the cake were the darkest and deposited the greatest amount of sediment on standing. The benzene-extracted oils from the wet-process germs contained more free acids than the oils obtained by that method from the dry-process germs, this being especially true of the oils from the cake. All the oils were refined in the same manner, with the exception of the benzene-extracted oil from the dry-process germ cake. Owing to the sediment present, this oil required a greater quantity of caustic. The oils were all deodorized by blowing them with a current of steam at 225 deg. C. (437 deg. F.) for 2 hours under a vacuum of 25 in. This treatment removes odorous volatile constituents and in the case of solvent-extracted oils tends to remove the final traces of the solvent.

The expeller oils showed the lowest loss on treatment with caustic; in the oils obtained by benzene extraction from the germs the loss was somewhat greater, and the benzene-extracted oils from the oil cakes showed by far the greatest loss.

In order to show whether the six oils under discussion differed to any extent as regards the usual physical and chemical constants, these constants were determined and the results summarized in Table II.

In so far as is indicated by the physical and chemical constants, these six oils do not appear to differ to any great extent. Such differences as exist are not any greater than would be expected in several samples of normal oil. Neither do the constants of these oils on the whole show any considerable divergence from those reported by other observers.

No material difference could be noted in the finished oils from the germs immediately after their preparation, but upon standing, some deterioration took place, and this was somewhat more noticeable in the benzene-extracted oils than in the expeller oils.

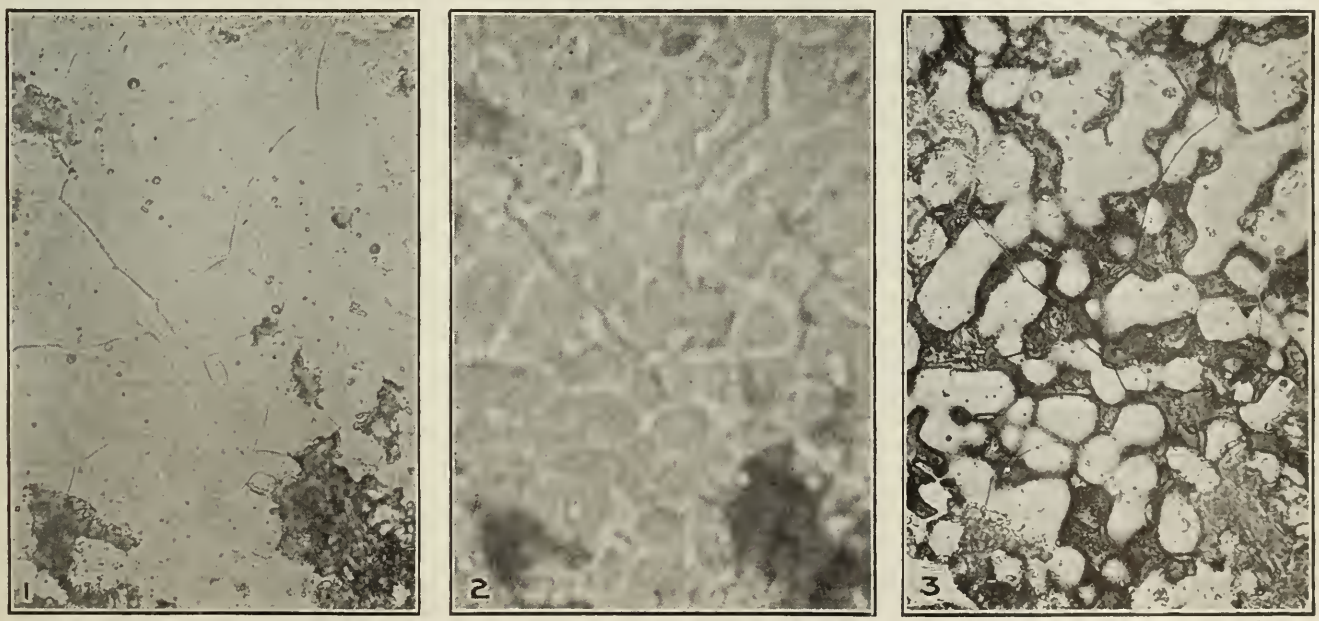
All the oils except perhaps that obtained by benzene extraction of the cake from wet-process germs were sufficiently light in color to make them suitable for salad and cooking purposes.

The oils obtained by benzene extraction from the two types of oil cake were inferior in all respects to the oils from the germs, that from the cake from wet-process germs being the poorer of the two.

A more thorough deodorization than that to which the oils could be subjected in these experiments might eliminate the remaining traces of either benzene or other odorous constituents, which no doubt account for the slight inferiority noticed in the benzene-extracted oils from the germs.

Phosphorus in Open-Hearth Steels.—Several years ago Dr. J. S. Unger, of the Carnegie Steel Co., prepared a series of 0.12 C basic and acid open-hearth steels, to which P was added while being cast, thus giving a series of ingots containing phosphorus in varying amounts from 0.008 to 0.115 per cent.[1] E. C. Groesbeck, of the Bureau of Standards, made some studies on small samples of these steels.[2] Samples of each were heated to 900 deg. C., held for about

[1] *Proceedings*, American Iron and Steel Institute, 1918, p. 172.
[2] Technologic Paper 203.



FIGS. 1 TO 3—CELLULAR STRUCTURE IN MEDIUM STEEL WITH 0.42 PER CENT P. × 500

Fig. 3—Same area etched with Stead's reagent.

15 minutes and cooled at a rate which carried them from 750 to 600 deg. C. in 4 hours, 2 hours, 1 hour, 30 minutes, 15 minutes, and 5 minutes respectively. There resulted a marked irregularity in the distribution and size of ferrite grains and pearlite kernels which cannot be ascribed to P content or method of manufacture. The grain size is roughly proportional to the time the sample remained above A_3, which represented the time available for growth of austenite grains. As the cooling rate increased, the relative number of pearlite kernels as compared to ferrite grains also increased, in conformity to the decreased opportunity for coalesence. No relation between P and amount of spheroidized cementite could be discovered. Brinell hardness (500 kg. load) appeared to increase consistently from 64 (P = 0.03) to 70 (P = 0.11), with a variation of $\pm$ 3, depending upon the rate of cooling.

In general the distribution of pearlite was very irregular; many times a large ferrite streak, shown to be high in phosphorus, contained along its rib a series of non-metallic inclusions. Groesbeck thinks this indicates that P segregates at the edges of the ingot crystals (dendrites), expelling therefrom the excess carbon which would also be expected to remain there. Normal picric or nitric acid etching often shows a shadowy cellular structure in the ferrite (Fig. 1) which is intensified if the field is a little out of focus (Fig. 2), a characteristic of very slight irregularities in a plane surface. Etching with Stead's reagent (Fig. 3) shows this cellular structure to be made up of regions high in P (light) and low in P (dark), a structure independent of the lines marking abutting ferrite grains. Such structures were developed in basic steels containing 0.05 P and more, and in the acid steels containing 0.03 P and more. Whiteley[3] has already studied the mutual distribution of C and P at various temperatures, and the present paper supports Whiteley's findings.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Pigments.—In processes for the preparation of oil pigment pastes from water pastes by grinding in the presence of a small quantity of a third substance or "activator," the following compounds are used as "activators": the oxides, hydroxide, acetate or basic acetate of lead, the borate, carbonate or basic carbonate of lead, cobalt, aluminum, magnesium, calcium, barium or strontium, or the carbonate or basic carbonate of manganese. The activator may be produced by reacting solutions in presence of the pigment. The pigment may be precipitated from colloidal suspension by the addition of an electrolytic or other coagulant. (Br. Pat. 173,350. Cookson & Co., Ltd., Newcastle-on-Tyne, and H. E. Clarke, Gateshead. Feb. 15, 1922.)

Dialkyl Sulphates.—Dialkyl sulphates are obtained by distilling alkyl hydrogen sulphates, or mixtures containing them, in vacuo so that only the small portion of liquid actually undergoing distillation is heated and so that the vapors and residue are rapidly removed from the point at which distillation occurs. For example, the liquid containing alkyl hydrogen sulphate may flow in a thin film over a heated surface, or down a heated coil or tube, or may be sprayed into the still or carried into the heated zone by a revolving drum or moving band. In an example a mixture of ethyl alcohol and fuming sulphuric acid is caused to flow by means of a revolving orifice down the inside of a vertical heated tube connected to a vacuum and condensing system; diethyl sulphate separates from the distillate, the remainder, consisting of alcohol, sulphuric acid, etc., being utilized in the next operation. Dimethyl, dipropyl and dibutyl sulphates may be similarly prepared. (Br. Pat. 175,077. British Cellulose Chemical Manufacturing Co., London, April 5, 1922.)

Phosphate Fertilizer.—Soluble phosphates are obtained by acting on a mixture of crude phosphate and alkaline sulphate with hydrochloric acid gas in presence of water. The addition of water may be effected by incorporating with the mixture loosening substances such as infusorial earth which can absorb moisture and still remain powdery. The required moisture may be added either before or after admixture with the crude phosphate and alkaline sulphate. The reaction is preferably carried out in stationary cylinders having stirring shafts, the mixture advancing slowly in the cylinder against a current of hydrochloric acid gas. (Br. Pat. 174,370. Not yet accepted. Rhenania Verein Chemischer Fabriken Akt. Ges. Zweigniederlassung Mannheim, Mannheim. March 22, 1922.)

Barium Hydrate.—In the production of barium hydrate from barium carbonate by forming barium silicate and decomposing this with water as described in specification 110,537, the proportion of silica to barium carbonate is such as to give a silicate of the formula $SiO_2.3BaO$ or a silicate intermediate between this and $SiO_2 2BaO$. The formation of the silicate from silica and barium carbonate or monobarium silicate and barium carbonate is effected in a rotary or tunnel furnace at 1,300 to 1,500 deg. C. The tribarium silicate or the intermediate silicate is treated with water to obtain barium hydrate and monobarium silicate, which is used for the next charge to be heated, and so on continuously. (Br. Pat. 174,052. Not yet accepted. C. Deguide, Enghien, France. March 8, 1922.)

Alkali Silicates.—Alkali silicates are obtained by treating barium silicates of the composition $SiO_2.1\text{-}3BaO$ with water and alkali carbonate or sulphate. Barium carbonate or sulphate is separated and may be converted into silicate by heating to 1,300 to 1,500 deg. C. with silica or silica and carbon. If the barium silicate is too basic, it may be treated with water to remove some barium as barium hydrate, leaving monobarium silicate. The sodium silicate obtained, containing some hydrate if basic barium silicates were used, may be caustified by lime. (Br. Pat. 174,581. Not yet accepted. C. Deguide, Enghien, France, March 22, 1922.)

Fatty Acids.—For the production of fatty acids, liquid hydrocarbons, such as the distillation products of rock oil or petroleum, are first treated with liquid sulphur dioxide for a sufficient length of time to remove all unsaturated impurities and an oxygen-containing gas is then blown through the unattacked residue, preferably in the presence of a base such as lime. (Br. Pat. 174,611. Not yet accepted. E. Zerner, Vienna. March 29, 1922.)

Metals and Alloys.—In an electric furnace method of making metals and alloys low in carbon and silicon from materials which are high in silicon and contain also oxides of one or more metals such as chromium, vanadium, manganese, tungsten, iron and nickel, the electric furnace is so worked that the voltage drop between a movable electrode and the charge is not less than 70. The constituents of the charge are finely powdered and intimately mixed and are preferably briquetted, the binder used being one not containing carbon, such as water glass or clay, and the briquets being dried by heating them to over 500 deg. C. For example a manganese-silicon alloy obtained by smelting a mixture of manganese ore, quartz and carbon may be powdered and mixed with manganese and dolomite, and the mixture briquetted with water glass, and the briquets, after being dried, may be reduced in an electric furnace operated as described above. The slag obtained may be used as raw material for the manufacture of silicomanganese. (Br. Pat. 174,618. Not yet accepted. Aktiebolaget Ferrolegeringar, Stockholm. March 29, 1922.)

Hydroxy-Quinones.—A chlorine-substituted anthraquinone is treated with a base in presence of an oxidizing agent, whereby a hydroxy group additional to those replacing the chlorine atoms is introduced. Alizarin, for instance, may be obtained from 2-chloranthraquinone by heating under pressure with caustic soda, sodium nitrate or chlorate, and water, the mixture being stirred. (Br. Pat. 174,101. A. H. Davies and Scottish Dyes, Ltd., Carlisle. March 8, 1922.)

Book Reviews

ANALYSIS OF FUEL, GAS, WATER AND LUBRICANTS. By *S. W. Parr*, University of Illinois. International Chemical Series. Third Edition. New York: McGraw-Hill Book Co., Inc. 250 pp. Price $2.50.

This book in its third edition has been expanded somewhat to make it quite a comprehensive text book for students in chemical engineering and mechanical engineering. It is an admirable admixture of text for study and outline of laboratory procedure to guide the experimental work of the student. It is also very suggestive of lecture demonstrations which would be effective in presenting before classes the important points of fuel problems. However, it has not been in any way laid out as a lecture guide and it is only indirectly that it serves this latter purpose.

In many particulars the book has been brought well up to date, including in some cases data and references for 1920 and 1921. However, in other sections, notably the one on petroleum, the data are still those of 1918. This is unfortunate for any volume appearing in 1922, since data for 1921 are already available.

In general the work has not been prepared for chemists, but rather for engineers. Moreover, it is clearly intended as a text and not a reference work. Bearing these two points in mind, one need have no hesitation in looking upon the revised work as a valuable addition to our technologic literature.

METRIC SYSTEM FOR ENGINEERS. By *Charles B. Clapham*, lecturer in the engineering department, University of London. 182 pp. New York: E. P. Dutton & Co. Price, $6.

The author states that "actual use of the metric system in the engineering industry in Great Britain has been steadily increasing, receiving much impulse during the recent war." There is a similar increase in this country, therefore a book of this sort will be very helpful to all who use the metric system in engineering calculation or measurement. The author is probably correct in stating that in the teaching of the metric system in the schools it is regarded as an alien subject to which a minimum of time need be given.

The author gives complete metric and English tables with the *exact* equivalents, but he also gives in each case the practical units and the *practical* equivalents, with rules and conversion charts for converting one into the other. There are many practical rules like the following which one would look far to find: "A weight in pounds is converted into kilograms by subtracting from it one-tenth of its own value and dividing the remainder by 2," error 0.3 per cent; and "a length in meters may be converted into yards by adding to it one-tenth of its own value," error 0.3 per cent.

Special attention is given to the use of measuring tools of the drafting room and workshop which may be graduated in metric units—e.g., verniers, micrometers and planimeters. Examples in connection with screw cutting and gear wheels are dealt with at length. The author points out a fact which will be a surprise to the uninitiated, that "all metric screws likely to be required can be cut on the usual English and American lathes, well within the accuracy required for manufacturing purposes, if one additional change wheel be provided" (p. 33). This arises from the fact that 1 in. equals very exactly 2.54 cm., hence it is necessary to have a wheel with 127 teeth, in addition to the wheels already in use.

Factors are given for the conversion of compound measures, such as British thermal units, horsepower, etc., also comparative tables of common engineering data, such as tensile strength and elastic moduli. A discussion of the C.G.S. system is also given, so that while the book is helpful to readers whose knowledge of mensuration is rudimentary, it is not without interest to the advanced student.

The author tries to take an unbiased position in regard to the compulsory adoption of the metric system in Great Britain and the United States, stating that this subject "is one upon which an isolated individual opinion would be of little value." He has, however, approached the subject from a constructive point of view and has done a piece of work which is essential to the transition to the metric system. His "brief survey of the controversy" is invaluable, since it throws much light (without heat) on the problem of the introduction of the metric system into industry from the standpont of the engineer. He repudiates the idea fostered by the opponents of the metric system that the adoption of metric units in metric countries is far from complete. He says "the use of such units [as the *sou* in France] is confined almost entirely to speech, and all written measurements and data appear in the official units." "At the present time the metric system is the only legal system of measurement in all the foremost countries of the world with the exception of the British Empire and the United States" (p. 143). In the newer and lighter branches of industrial work the metric system is met with to a considerable and ever increasing extent as regards lengths for manufacturing purposes. With some firms and some particular sections it is the only system employed (p. 143), and he gives a list of such types of firms. "In purely scientific work the metric system is alone used" (p. 144). "The English-speaking nations are the only non-metric ones of importance, and other nations cannot be expected to revert from metric to the Imperial system" (p. 146). "The real importance of the non-compliance of Britain and America with the international system is that rapidly developing countries using the metric units may be better catered for by the metric nations of Europe" (p. 146). In regard to the cost of the change, which is the great argument of the opponents of the metric system, he says, "It is to be feared that many false objections have been put forward" (p. 148). An authoritative statement of this character from an engineer who has made an unbiased study of the calculations, etc., involved in the change is very gratifying to the chemist who longs for the day when our cumbersome system can be entirely abandoned without hardship.

Eugene C. Bingham.

STUDY QUESTIONS IN ORGANIC CHEMISTRY. By *Alexander Lowry* and *Thomas B. Downey*. 92 pp. New York: D. Van Nostrand Co. Price $1.

The authors have put in pamphlet form a series of classified questions which are to serve as a guide and outline in the study of elementary organic chemistry. In addition they have appended a rather complete list of the more common reference books on the various phases of the subject.

This method of focusing attention on the subject has always proved valuable, in the experience of the reviewer, in teaching organic chemistry. The idea of using the same set of questions repeatedly, however, is open to criticism.

First, experience shows that when no changes are made in questions from time to time, completely answered sets are generally passed down from one class to the succeeding class. This practice, of course, defeats the very purpose of the questions. Second, due to wide variations in classes from year to year and to differences in presentation, the emphasis on the various topics has to be shifted. To meet this situation, it becomes necessary to frame new or at least different types of questions.

The material covered by the questions is fairly wide in scope. There are, however, certain omissions from the subject of optical activity—particularly optical resolution, symmetric synthesis, muta-rotation and the Walden inversion. It would seem that a separate section devoted to this subject would be better than the isolated questions scattered throughout the pamphlet. Except for the omissions just noted, the questions can be recommended as complete and satisfactory.

The pamphlet should prove particularly useful to those outside regularly organized courses in organic chemistry who are studying the subject or to those who, although they have had a complete course, have been out of contact with the subject and wish guidance in reviewing it.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Chemical Equipment Manufacturers Organize Trade Association

The Chemical Equipment Manufacturers Association was organized at a meeting of representatives of the industry held in the Chemists' Club, New York, on May 11. The association is the outgrowth of a movement begun last fall by twenty-five manufacturers of chemical equipment who were exhibitors at the Seventh National Exposition of Chemical Industries. They were brought together at that time to consider some matters relating to the Exposition, but realizing that there were other and perhaps more substantial reasons for organizing a permanent trade association, they have been active since last fall investigating the possibilities of an association to consider problems common to manufacturers of chemical equipment. All development work has been under the direction of an executive committee consisting of J. George Lehman, chairman; A. A. Holmes, secretary; Paul O. Abbe, P. C. Kingsbury and C. H. Kimberly.

The meeting on the 11th inst. was directed by Dr. C. H. Kimberly, who has been in active charge for some months past owing to the absence of Mr. Lehman, chairman. The following manufacturers were represented at the meeting:

Company	Representatives
United Filters Corp.	R. C. Campbell
Read Machinery Co.	A. N. Bowes
The Dorr Co.	G. E. Walker
Paul O. Abbe	Paul O. Abbe
Maurice A. Knight	Samuel J. Baril, M. Sultzer
Quigley Furnace Specialties Co.	H. T. Matthew
Vallez Rotary Filter Press, Chemical Equipment Co.,	C. L. Bryden
Duriron Co.	M. W. Smith
Nash Engineering Co.	C. B. Wright
Walter E. Lummus Co.	W. E. Lummus
Bethlehem Foundry and Machine Co.	A. H. Stevens
Precision Instrument Co.	L. D. Vorce
E. B. Badger & Sons Co.	A. A. Holmes
Schutte & Koerting	C. H. Kimberly
Aterite Co.	D. L. Dowling
General Ceramics Co.	R. S. Beecher
Oil, Paint and Drug Reporter	E. P. Specht
Drug and Chemical Markets	D. H. Killeffer
Journal of Industrial and Engineering Chemistry	H. E. Howe
Chemical Catalog Co.	F. W. Robinson, E. G. Nellis, F. M. Turner, Jr.
Chemical Age	R. H. McCready, Lloyd Lamborn
Chemical & Metallurgical Engineering	H. C. Parmelee, Irving Fellner

Addresses on Trade Associations

At the morning session there were two addresses on the general subject of trade associations: One by E. W. McCullough, chairman of the committee on fabricated production of the Chamber of Commerce of the United States, and the other by William A. Durgin, in charge of the Division of Simplified Practice in the Department of Commerce.

Mr. McCullough spoke from a broad experience with trade associations, particularly as a former secretary of an association of agricultural implement manufacturers. He emphasized the necessity of having a definite goal in starting an association of this kind. A prime necessity is a good secretary who will function as an executive and not merely as a clerk. He must not be handicapped by lack of funds, and preferably he should hold office continuously. Mr. McCullough pointed out the necessity of co-operation between a trade association and such government agencies as the Department of Commerce and the Federal Trade Commission in order that the government can be fully advised of the problems and needs of the industry.

Mr. Durgin outlined the reorganization of the Department of Commerce by Mr. Hoover and emphasized the fact that business is better represented today in the administration at Washington than it ever has been before. The Department of Commerce is functioning as the servant of business, but it can continue so to function only if business will co-operate with it and form close contacts through trade associations. By this means business will be in a position to obtain sympathetic attention from the government. Mr. Durgin dwelt on the subject of simplification in manufacture as one of the possible activities of the Chemical Equipment Manufacturers Association.

In the discussion which followed these two addresses representatives of the industry made tentative suggestions as to possible activities for the association. Among these were questions of standardization, guarantees of equipment, trade practices and activities of second-hand dealers.

At the afternoon session those present adopted the constitution and bylaws, which is printed below. By vote of those present, the executive committee appointed last fall will continue to direct the affairs of the association until permanent officers are elected. It will act as a nominating committee to prepare for an election to be held in September and it will also serve as a membership committee.

At the evening session the association was addressed by three representatives of trade expositions, Alfred Reeves, manager of the Automobile Chamber of Commerce; Robert Everett, secretary-manager of the Association of Ice Cream Supply Men; and F. W. Payne, of the National Exposition of Chemical Industries. The remarks of the latter were of particular interest on account of the light thrown on some matters in connection with the Chemical Exposition which had not been thoroughly understood or appreciated by exhibitors.

Constitution and Bylaws

Section 1—Name and Objects

The name of this association shall be Chemical Equipment Manufacturers' Association. The purpose of this association shall be to foster trade in chemical process equipment. In order to do this it shall be the aim of the association to:

Encourage high standards in the industry.

Promote a better knowledge of conditions controlling the industry's development.

Take steps to bring about definite understanding as to professional services rendered to purchasers in connection with sale of equipment.

Investigate conditions surrounding the resale of equipment originally produced for specific purposes.

Disseminate information as to methods of arriving at correct costs.

Standardize trade phrases.

Collect and disseminate information as to design, raw material and construction.

Take suitable and timely notice of, and action upon, matters of legislation, both national and state, which affect the members of this association.

Collect and disseminate market statistics both domestic and foreign.

Collect and disseminate information as to labor conditions and relations.

And enter into such other legitimate trade association activities as may be deemed in the interest and welfare of the industry.

It is distinctly understood that this association will not

undertake any activity which will restrain trade, limit production or competition, regulate prices, or otherwise be in violation of the law.

Section 2—Membership

Membership shall be divided into three classes: active, associate, and honorary.

Active membership shall be composed of manufacturers and their agents and others engaged in the manufacture and sale of equipment and accessories used in the chemical industries and industries using chemical processes. Only active members shall vote and hold office.

The associate membership shall be composed of such individuals, firms or corporations as are interested in the activities of the association. For example, consulting engineers and technical publications.

Any individual, firm or corporation qualifying for either of the above classes of membership, upon recommendation of the membership committee and the majority vote of the board of directors, and upon subscribing to the constitution and bylaws of the association, shall be declared elected to membership of this association. Payment of the annual dues shall be required within 30 days after election.

When a member has ceased from active participation in the work of the association, either because of retirement from business or change of position and has rendered distinguished service, either to the association or the industry, he may be accorded the rank of honorary member.

During term of office the presiding officer of affiliated technical societies such as A.C.S., A.I.C.E., A.O.C.S., etc. may also be accorded the rank of honorary member.

The proven participation of any member in any agreement to restrain trade, limit production or competition, regulate prices, or of other conduct prejudicial to the interests of the association, shall be reason for immediate expulsion by a majority vote of the board of directors.

Section 3—Board of Directors

There shall be a board of directors of seven members consisting of the president, ex-officio, and six others elected by the association. Of the original board, two members shall serve for 3 years, two members for 2 years and two members for 1 year from date of election. Thereafter, members of the board shall be elected annually to serve for 3 years. They shall have general supervision over the affairs of the association.

Section 4—Officers

The officers of the association shall be: president, vice-president and a secretary-treasurer.

Officers shall be elected at the annual meeting of the association. Ninety days prior to the annual meeting the president shall appoint a nominating committee of three who shall select at least two candidates for each office to be filled. Any other candidates can be nominated in writing by five or more active members of the association. All nominations shall be placed in alphabetical order on the ballot, which shall be mailed 30 days before the annual meeting. The ballots may be mailed to the secretary or brought to the annual meeting in envelopes unmarked, these envelopes being inclosed in others having the signature of the member voting. The nominee for each office receiving the highest number of votes shall be declared elected. In case of a tie the board of directors shall elect one of the two.

No member of the association shall be elected to the office of president more than twice in succession and there shall be a lapse of at least 3 years before he shall again be eligible for such position. The president and vice-president will hold office 1 year or until their successors are elected and qualified.

Section 5—Duties of Officers

The duties of the officers shall be as follows:

The president shall preside at all meetings of the association and act as an ex-officio member of board of directors. In his absence, the vice-president shall preside. In the absence of both the president and the vice-president, the members present at any meeting may by a majority vote, elect a chairman pro tem. to preside over such a meeting.

The following standing committees shall be appointed annually by the president, each to consist of at least three members: Membership, Standardization, Business Ethics, Industrial Relations, Statistics, Legislative and Publicity.

The secretary-treasurer shall be appointed by the board of directors and be directly responsible to them. The secretary-treasurer shall keep proper records of the meetings and all formal actions of the association and its committees. He shall have the custody of all its records and papers in general. Statistics and other confidential information received from members shall not be communicated to other members without specific permission of the member giving same, but nothing in this section shall be construed to prohibit the compiling of records and statistics *en bloc* or in totals and the furnishing of such compilations to all the members. He shall on request give to the president the names of members reporting and not reporting. He shall on order of the president issue written notices of all meetings of the association to members. He shall have the custody of and receive and disburse all funds of the association. He shall give bond in such sum and with such surety as the board of directors shall determine and such bond shall be held in custody of the president.

The books and accounts of the secretary-treasurer shall be audited at least once a year by a suitable disinterested accountant to be selected by the board of directors. Such accountant shall not be connected with the chemical process equipment industry.

The secretary-treasurer shall hold office during the pleasure of the board of directors.

Section 6—Dues

The annual dues of the active members shall be $100.

The annual dues of the associate members shall be $50.

Honorary members shall not be subject to either dues or assessments.

There shall be an initiation fee, the amount to be determined by the board of directors and it shall become effective when so determined.

The first annual dues are payable within 30 days of election; thereafter dues are payable quarterly at the option of the member. Membership shall be dated from the first of the quarter during which the member is elected.

Any member who shall become 90 days in arrears for dues and assessments shall cease to enjoy any benefits of the association. If he shall become 6 months in arrears he shall be subject to expulsion at the discretion of the board of directors.

Funds required in excess of revenue from dues are to be secured by assessment upon active members upon a basis to be determined by the board of directors and accepted by the members of the association. The association may also accept gifts, subscriptions and other funds for specific and general purposes.

Section 7—Meetings

The annual meeting shall be during the month of September and at the main office of the association.

The president shall call all other meetings of the association. In his inability, the vice-president shall have power to do so. A meeting shall be called at the written request of any seven members of the association.

At any business meeting the association members may be represented and vote as follows: Representation at the meetings of the association shall be only by designated representatives of the members, each member to have one vote.

Section 8—Publicity

The records of the association, its files and its correspondence and its meetings shall be open at all times to any public official who in the performance of his duties is legally authorized to investigate the workings of the association; the fundamental object of the association being perfect frankness and openness in all of its activities.

Section 9—Amendments

This constitution may be amended by a vote of three-quarters of the members present at any annual meeting,

provided a notice of such amendment has been sent to all members by the secretary 60 days in advance of such meeting.

SECTION 10—ORDER OF BUSINESS

The order of the business shall be as follows:

1. Calling the roll.
2. Reading minutes.
3. Election of officers.
4. Reports of officers.
5. Reports of committees.
6. Receiving communications.
7. Unfinished business.
8. New business.

SECTION 11

On points not specifically covered, Robert's Manual shall be considered as basis for rules of order.

Browne and Dow Address Joint Meeting of New York Chemical Societies

New York chemists who missed the joint meeting of the local chemical societies held under the direction of the American Section of the Société de Chimie Industrielle in Rumford Hall on May 12 have much to regret. The evening's program, featured by two intensely interesting addresses dealing with different phases of chemical history, proved to be one of the rarest treats of the season. Dr. C. A. Browne, chief chemist, New York Sugar Trade Laboratory, who is one of our few outstanding recorders of the history of American chemistry, spoke on "Early Chemical Industry in America—A Few Comparisons of Past With Present Conditions." Dr. Herbert H. Dow, president, Dow Chemical Co., followed with a very vivid and engaging account of some of his own experiences "in extracting dividends from chemical processes."

Dr. Browne's diligent searches into the archives of the Congressional Library have recently revealed records of the first chemical operations in the United States. In 1535 a party of Spaniards on their way into Mexico found certain pigments and bright minerals among the members of an Indian tribe and after tracing these to their sources, they discovered crude metallurgical operations in which the natives were smelting and refining precious metals. From this beginning we can follow the progress of the Spaniards, and later on the French, in exploiting the gold and silver of the new continent. In the New York colony the first of the chemical industries was the refining of sugar by the Dutch. As early as 1689 a large sugar refinery had been built in Liberty St. and continued its operations almost up to Revolutionary times. John Winthrop, early Governor of Connecticut, however, may be said to be the first American industrial chemist. Over 250 years ago he was manufacturing salt, recovering saltpeter and sulphur and making gunpowder. Dr. Browne, in his searches through the files of the Massachusetts Historical Society, has unearthed a number of interesting documents showing the alchemistic experiments and researches of this early American investigator.

The most startling of Dr. Browne's revelations, however, was the comparison of economic conditions in the chemical industry in the period 1806-1826 with those which have existed since 1914. Developments in the early days were almost identical with those we have just experienced. The expansion to meet the demands of the Napoleonic wars, followed by those of our own war of 1812, was repeated in 1914 and in 1917-18. Following the war of 1812 our chemical ancestors made every effort to hold onto their industrial gains and petitions for embargoes, tariff protection and patent legislation were as evident then as they have been in recent years.

A Bromine Industry Developed Under Difficulties

As is often the case in the commercialization of a chemical process, the early development of the American bromine industry was beset with almost insurmountable difficulties. But Mr. Dow early demonstrated that he was as much a business man as a chemist and the great industry at Midland which bears his name is evidence of his success in solving financial as well as technical difficulties. Beginning with his early and unsuccessful attempt to recover lithium from a salt brine near Cleveland in 1888, the speaker recounted his personal experiences which gradually culminated into a profitable method for extracting bromine. After his first bromine adventure had failed, Mr. Dow went to Midland, Mich., and purchased a brine-well property for $100. This was in 1890 and the next 5 years was spent in costly development and experimentation with plant processes. The first plant troubles were with the brine pumps and final success of the operation may be said to date from the development of an improvised check valve used on this particular pump.

Mr. Dow concluded his talk with a review of the sidelines developed in connection with the industry and as example showed how Dow metal, the new magnesium alloy, had its origin. This alloy has certain interesting properties which indicate that it may be destined greatly to affect the construction of the internal combustion engine.

Resolutions in Memory of Dr. Baskerville

This was the first meeting of the American Section of the Société since the death of its vice-president, Dr. Charles Baskerville, and President J. Enrique Zanetti read the following resolution which was unanimously adopted as a respectful recognition of the memory of this illustrious investigator:

> The Société de Chimie Industrielle has suffered a great loss in the passing of Dr. Charles Baskerville. He was able in counsel, sound in scholarship, kind and generous in disposition and prolific in invention. As a man of science, as professor and as head of the department of chemistry of the College of the City of New York, he was at once competent, clear of vision and keen of understanding; a constant friend to those serving with him and under his direction and an enduring source of inspiration to his students. He was both a gifted teacher and an administrator of rare ability.
>
> Besides his endowment of far vision and his diligence in research along with the fulfillment of his many duties, he was a joyous companion and bountiful in the benefactions of his friendship. In this he was always guided by magnanimous generosity toward others while holding close to high ideals of thought and action for himself.
>
> His presence added distinction, learning and wisdom to the Council. His death is a heavy burden, his memory a precious inheritance.

Patent Convention With Germany Revived

After an extended study of all the ramifications of the proposal that the Patent Convention of 1909 with Germany be permitted to lapse, the State Department decided to revive the convention, and notice to that effect was transmitted to the German authorities prior to May 11, which was the time limit for such notification. The revival of this convention gives the holders of American patents registered in Germany immunity from the working clause in the German patent law. Strong pressure was brought by the War Department and the chemical industry against the revival of the convention. The War Department is anxious to obtain the enactment of a working clause to apply to all patents registered in the United States. The American chemical industry has comparatively few patents registered abroad. On the other hand Germany has a large number of patents registered in this country which are not being worked.

Manufacturers of machinery in the United States were among those who were most strongly in favor of reinstating the convention with Germany. It was stated that it would cost machinery manufacturers millions of dollars to undertake the manufacture of their patents in Germany.

The effective date of the revival of the treaty is May 8, 1922. This means that no change can be made without 1 year's notice. The Patent Committee is going ahead with the new Stanley bill, which is the bill drafted by Henry Howard, president of the American Institute of Chemical Engineers. Since the urgency for legislation has passed, it is probable that action on the bill will lag, although the hope is expressed in some quarters that favorable action will be taken.

Annual Conference on Weights and Measures

The fifteenth annual conference on weights and measures will be held at the Bureau of Standards at Washington, May 23 to 26. These conferences are attended by government officials interested in weights and measures and by weights and measures officials of states, cities and counties. The sessions also are attended by manufacturers of apparatus and by representatives of industries interested in the general subject. A feature of each of these conferences is the display of manufacturers' exhibits of weighing and measuring apparatus.

The program includes an address by the Secretary of Commerce. C. A. Briggs, of the Bureau of Standards staff, has taken as his subject "The Metric System: How Would It Be Put Into Effect?" H. W. Bearce, also an official of the Bureau of Standards, will discuss "The Fundamental Standard of Length."

Technical and Industrial Photography to Be Fostered by New Society

At a meeting held in the Chemists' Club, New York City, on May 10 the organization of a society of technical and industrial photographers was consummated. The new society will be known as the Technical Photographic and Microscopical Society. Officers elected were as follows: President, James McDowell, of the Sharp & Hamilton Manufacturing Co., Boston, Mass.; secretary-treasurer, T. J. Keenan, editor of *Paper;* vice-presidents, J. H. Graff, of the Brown Co., Berlin, N. H., and B. Grotta of the Atlas Powder Co., Tamaqua, Pa.

A luncheon meeting of the society at the Hotel Astor, New York, is scheduled for June 15, at which time the members will be addressed by speakers prominent in the field of industrial photography. At this meeting additional steps will be taken for the establishment of a permanent organization, and an invitation is extended to all individuals or organizations interested in technical and industrial photography to attend or send representatives to this meeting.

The aim of the organization is to promote the advance and extension of photography in its applications in industry and business by co-operation among those engaged in the work and among the industries which the art serves. The membership will be made up not of photographers primarily, but of technical men who depend upon photography for aid in their control and research problems. Industrial and technical photography should not be confused with commercial photography, although these two branches often overlap, and the commercial photographer in many instances has done much for the full appreciation of the value of photography in industry and science. The problems of industrial photography are many-sided and interwoven so much with the knowledge of other sciences—namely, administration, engineering, chemistry, physics, optics and mathematics—that it is absolutely impossible for them to be covered by the average commercial photographer.

The Field of Technical Photography

The society will be concerned in work done with the ordinary camera as a tool of management, making photographic records of control and record boards, photographs of accidents and damages, photographs demonstrating evidence of waste and salvage, demonstration of safety ideas and accident prevention, for copying drawings and documents, standardizing records, as an aid to the engineer making progress reports of construction, and illustrations for field investigation, trade reports and industrial reports.

Another important field is in photomicrographic and macrographic work. This work, which formerly was only done by the scientist in pure research, is now more and more used to solve daily commercial and industrial problems. It is of increasing importance in metallography, textile, pulp and paper industries, cement, explosives, colloidal solutions, physical chemistry, bacteriology, rubber, leather and paint industries. The study of the raw material or the finished product is, however, only a small part of the work. The biggest value is in ability to record and compare the result of the different chemical and physical processes of production.

A third field of interest covers photographic work needing specially constructed equipment. Many industrial and technical problems in photography require specially designed apparatus and equipment, of which it is only necessary to mention a few, illustrating the immense scope of this work, as for example, special equipment making it possible to take photographs of physical phenomena and illustrating the workings of physical laws, photomicrographic moving picture machines, and special moving picture cameras, making it possible to study the detail of motions or the breaks or stress of physical tests.

Society Plans Exhibit

An exhibition of technical and industrial photography showing some of its unique and interesting applications will be given by the new society at the Chemical Exposition in New York in September. The exhibit will include samples of work on textiles, pulp and paper, leather and other industries, besides a display of new apparatus used in modern technical photographic laboratories.

Research Last Branch of C.W.S. to Be Cut—Sentiment on Chemical Warfare Changing

After July 1, unless the Senate should increase greatly the amount to be appropriated for the Chemical Warfare Service, numerous activities of the Service will have to be skeletonized and reduced to a standby status. Research will suffer least of all. It is intended to maintain research at the expense of every other activity.

Evidence is reaching the Chemical Warfare Service that the adoption of the so-called gas treaty has not been entirely adverse to the development of chemical warfare. The discussion of the treaty has had an educational effect in that it has acquainted additional thousands with the fact that chemical weapons are the most humane which can be used in warfare.

Gradual Change in Sentiment Toward C.W.S.

Formerly a considerable portion of the army itself looked upon chemical warfare with much skepticism. The General Staff was avowedly hostile to the importance which Congress attached to the Service and was inclined to belittle its possibilities. Sentiment in the army itself has changed to the point where practically every officer is an advocate of chemical warfare. A notable exception is General Pershing. No satisfactory explanation ever has been put forward for the change in the views on this subject of the General of the armies. It is fully believed that he expressed his real personal views in his testimony before the Military Affairs Committee, and that he was influenced at the time the treaties were being negotiated by the desire of the Secretary of State to align the United States with what would be generally understood throughout the world as the more humane policy.

Much significance is attached by the army and navy air services to the capture of a naval squadron by Chinese air forces. In the face of effective bomb dropping the whole squadron soon ran up the white flag. While the bombs used were of the high-explosive character, it is pointed out that even more prompt results could have been obtained had they been gas bombs and the loss of life probably would have been avoidable.

Columbia Announces Summer Courses

A series of summer courses in advanced branches of chemistry and chemical engineering, physics, electrical engineering and mathematics is announced by Columbia University, New York City, for the session July 10 to Aug. 18, 1922. The courses in chemistry include general inorganic, colloid chemistry, physical chemistry, food chemistry and organic chemistry. The chemical engineering program includes courses in fuel chemistry, illuminating gas, industrial chemistry and research engineering. Full details will be sent upon application to the secretary of Columbia University, New York City.

House Bill Would Provide for Development of Helium

The conservation, production and exploitation of helium gas under the Interior Department is contemplated in a bill introduced by Representative Kahn of California. The bill transfers all helium activities to this department and would forbid the exportation of helium except upon approval of the President. Helium would be first supplied to meet requirements of the War and Navy Departments, the surplus to be leased or sold to citizens of the United States or to commercial companies, corporations, institutions of learning or research or other agency so incorporated that the control of said companies, corporations, institutions of learning or research or other agency cannot pass out of the control of American citizens.

The bill provides that the Secretary of Interior shall purchase gas and acquire extraction rights in gases and to lease or purchase lands or the gas and oil rights in lands for the purpose of conserving and producing helium. It also directs the Department of the Interior to explore for, drill and develop such lands, rights in land, gases and rights in gases, for the purpose of securing such helium as may be required, and to store, sell or dispose of any natural gas, petroleum or valuable byproducts obtained in such development and to store the helium so produced.

Under the provisions of the bill, the Secretary of the Interior would be authorized to carry on experimental work relative to the production of helium and to acquire, establish and operate or cause to be operated such plants, accessories and facilities and to acquire rights pertaining thereto as may be necessary for the production and storage of helium.

The bill carries an appropriation of $5,000,000 for development purposes. It directs the Secretaries of War and Navy to submit annually to the Interior Department their estimated requirements for helium to be supplied or conserved for the next fiscal year.

Senator Moses Contributes His Plaint to Testimony of Dye Investigation

Senator Moses of New Hampshire, one of the instigators of the dye investigation, contributed to the testimony before the committee for the first time on May 10, when he called several matters to the attention of the committee through William P. Pickhardt, director of Kutroff, Pickhardt & Co., New York City. Through Mr. Pickhardt, Senator Moses presented to the committee a series of memoranda and correspondence, which Mr. Pickhardt said represented some of the objections held by consumers and by Senator Moses to the protection sought by the American organic and chemical industry.

It was evident from th s correspondence that the New Hampshire Senator has been active in gathering information for the Amoskeag Manufacturing Co., of New Hampshire, and in aiding it to obtain licenses for the importation of German dyes. The correspondence was included in the record of testimony.

Consumers Complain of Licensing Delay

As evidence that there is cause for complaint on the part of consumers of dyes, Senator Moses called attention to the case of the Amoskeag Manufacturing Co. in obtaining an import license for indanthrene blue BCS. Application for the license had been made in this case on Nov. 14 and it was granted on Dec. 3, according to Mr. Pickhardt. Twenty-seven barrels of this dye were imported for three consumers by his company, but after the dye had been distributed to these consumers the dye and chemical control section of the Treasury had ordered it all returned to New York because of a fear that the dye was not as represented and was in reality merely a substitute for an American dye which would give the same satisfaction to users. Later on, Mr. Pickhardt said, further experiments and tests showed the dye to be as was represented and the shipment was released and the dye again was put on the importable list, Feb. 16 last.

Senator Moses had also requested him to present to the committee, Mr. Pickhardt said, a memorandum prepared by F. S. Dickson, chief of the dye and chemical control section of the Treasury Department, dealing with the authority for importation of German dyes through the reparations commission and the Textile Alliance, under the peace treaty. The New Hampshire Senator also had Mr. Pickhardt place in the record a report made to the Textile Alliance by Edward S. Chapin, its representative in Paris, and another report by Mr. Chapin to the State Department, and other correspondence on various phases of the general situation, including correspondence with Mr. Pickhardt and the Amoskeag Manufacturing Co.

Describes Activities of Kuttroff, Pickhardt & Co.

History of the activities of his firm, which prior to the war was the exclusive agent in the United States of the Badische Anilin- und Soda-Fabrik, one of the largest members of the present German cartel, was begun by Mr. Pickhardt following his presentation of the material prepared by Senator Moses. Mr. Pickhardt said that there had been so much talk about his own activities that he wished to give the committee a complete and detailed history of them, particularly with regard to his efforts to import German dyestuffs since the signing of the armistice.

Imported dyes handled by his concern since the armistice, he said in response to a question, were very much in the minority in value and a much smaller percentage in quantity of the total of American and foreign dyes handled.

Delay in getting German dyes needed by American consumers following the armistice was "due to a desire on the part of special interests to eliminate importers from the dye industry," Mr. Pickhardt said, and this desire had been placed above the desire of the State Department, which was solely to obtain dyes needed by American consumers.

Say Consumers Are Back of Manufacturers

Thomas Frusher, of the United States Woolen Co., stated that "90 per cent of the consumers of the country are opposed to the embargo, but they say that if the dye men need another year, why, give it to them," he declared. "I want to help the American industry, but I don't want an inefficient government organization telling me that we can have this or must try a substitute for that."

Mr. Frusher deplored the necessity of obtaining a license to import dyes which are not made in this country. His objection was based on the delay involved in obtaining a license, a circumstance which Mr. Frusher laid at the door of those charged with administering the system. He urged that the government publish a monthly list of dyes made in the United States and that consumers be permitted to import without license all dyes not named therein.

Bureau of Mines Asks Aid of Industry in Compiling Coal Storage Data

The Bureau of Mines has issued a call to industries using coal for help in compiling exact information on the problems involved in the storage of coal. Every coal user is requested to give the Bureau the benefit of his views and conclusions on the subjects of handling and transportation costs and the investment, fixed charges, etc., involved.

While there has been much agitation of the possibilities of coal storage for giving more regular mining and movement of coal, there is very little exact information available. It is for such exact data and working costs that the bureau is calling upon the industries.

Among the specific points on which information is desired are the following: Method of storage, location with reference to point where coal is used, quantity stored, methods of preventing spontaneous combustion, method of handling fires, devices used for observing temperature, deterioration in stored coal, danger point as regards temperature, tonnage per acre, depth of pile, kinds of coal stored, cost of plant, maintenance and handling and effect of climate on stored coal.

Information on these subjects should be sent to F. R. Wadleigh, Fuel Division, Department of Commerce, Washington, D. C.

Senate Drags Through "A's" of Chemical Schedule Strongly Supporting Committee Amendments

If the progress made by the Senate on paragraph 1 of the chemical schedule is a criterion, snow will fly long before the discussion of the measure is concluded. Consideration of the tariff began on April 20. It has been demonstrated clearly that the committee has the votes to put through practically all of its amendments. Despite this fact, progress has been very slow. The Senate has been held in session for much longer periods each day than is the custom. The rules in regard to interruptions are being enforced with more than the usual rigor, but despite the application of the spur, it has been very difficult to bring the Senate to the point of voting on the amendments.

While the acid paragraph is regarded as an important one, the commodities contained in it would not have provoked the amount of discussion devoted to them had it not been for the fact that this is the first paragraph of the bill. This naturally has led to much discussion of principles underlying tariff making.

Senate Stands by Committee

When the Senate does reach the point of a vote, very frequently no roll call is required. When the roll is called, the support for the committee amendment is overwhelming. For instance, the committee increased the duty on lactic acid from 1½ cents to 2 cents per pound. The vote on that amendment was 40 to 23. The committee proposal to make the duty on arsenic acid 3 cents per pound and on white arsenic 2 cents per pound was carried by votes of 40 to 18 and 34 to 16 respectively.

That the majority is standing with the committee is evidenced further by the fact that amendments to increase rates of duty are being voted down. Senator McCormick, of Illinois, for instance, proposed to increase the duty on formic acid from 4 to 6 cents. It was contended on behalf of this amendment that a 6 cent duty is necessary to place the American industry on an equal footing with manufacturers of that acid in Germany, nevertheless the proposal was voted down decisively. In the consideration of that item, Senator McCumber explained that the specific duty of 4 cents a pound practically is the equivalent of the 25 per cent ad valorem rate assessed in the House bill. In that connection Senator McCumber explained again that it is the policy of the committee to impose specific duties wherever possible so that the amount collected will be the same regardless of the country of origin. This led Senator Hitchcock to ask if it is the purpose to shut out chemical imports from Germany. Senator McCumber replied that the 4-cent rate will not reduce the volume of formic acid being imported.

Foreign Markets and Competition

During the debate figures were presented showing that we are selling more chemicals to Germany than we are purchasing from that country. Senator McCumber expressed the belief that such a condition would not be lasting. "We know," he said, "something about the cheap labor and the cheap production of chemicals in Germany. I do not expect we are going to continue to sell chemicals to Germany."

"For 50 years," declared Senator McCumber, "we have sold Great Britain two to three times as much as we have bought from her, the balance of trade always has been immensely in our favor, yet Great Britain was able to buy our products. I think in a very short time Germany will drive the United States out of the markets of South America and many other countries, and that she will produce a sufficient balance of trade in her favor to use the same amount of money for purchasing American products. I do not think there has to be an exact balancing of trade as between any two nations."

In reply to the suggestion that the allied countries could pay their obligation to this country only in goods, Senator McCumber expressed the opinion that it would be better to lose the money then to allow these countries to pay us in goods when that would mean the closing of our own mills and factories. He also expressed the opinion that prices never will recede to the pre-war level. He pointed out that despite the deflation which has taken place, the volume of currency per capita in the United States at this time is double the pre-war volume.

Long Debate on Arsenic

The proposal to put a duty on arsenic—a commodity which can be produced easily in quantities in excess of domestic requirements—occasioned lengthy debate. It was justified by the committee on the ground that the smelters are compelled to produce arsenic so as to prevent damage to vegetation, and that they should be permitted to obtain at least the cost of its recovery. It was pointed out that with the development of the smelting industry in Japan, that country is offering arsenic at American ports at less than the cost of production. Unless this duty is granted, it would have the effect of handicapping our ability to export metals in that the losses on arsenic would have to be added to the cost of metal production.

Engineer Volunteers Help to Government in Reaching Muscle Shoals Decision

William McClellan, president of the American Institute of Electrical Engineers and a member of the executive board of the Federated American Engineering Societies, appeared before the Senate Committee on Agriculture, May 9, to give his views in regard to the handling of the Muscle Shoals project.

He emphasized the desirability of protecting the existing construction and equipment against deterioration and advocated the formation of an engineering board of review to recommend to Congress a general plan of procedure.

Dr. McClellan bound himself to place at the disposal of Congress a committee of engineers with commercial experience who would recommend a general plan for the handling of the project from a business standpoint. He said he would arrange, through the American Institute of Electrical Engineers or through the Federated American Engineering Societies, for the services of such a committee, which would be composed of disinterested men of thoroughly established reputation.

Government Needs Aid of Engineers

He also told the committee that the government should not act except on the basis of unbiased, competent, professional and business advice. "It is perhaps not unfair to say," he asserted, "that all those engineers and business men who have made detailed studies of the project have done so for some reason of their own and did not look at it from the government's standpoint. The disposal of Muscle Shoals is not a technical, engineering proposition. It is a commercial matter. The only way for the government to get an impartial review of the commercial and engineering features of the situation is for the committee of the Senate and the committee of the House jointly to request a group of not less than five engineers, who have had adequate commercial experience in large projects, to take all of the data, statements and reports which have been submitted and report to the committees what the government should do.

"The government under no circumstances," continued Dr. McClellan, "should alienate its nitrate plants until an adequate plan is agreed upon for the completion of these plants or the construction of nitrate plants at some more favorable points, should such places be found. During the period of investigation the works at Muscle Shoals can be adequately protected against deterioration. Such protection of interrupted construction work is very common among commercial companies. The government can well afford to appropriate money to render streams navigable and to regulate flow, particularly at headwaters, so as to improve the stream for power purposes."

Senator Caraway of Arkansas charged that the fertilizer trust had instituted rival offers for the nitrate plants in an effort to prevent Congressional acceptance of any offer. He likened delay in consideration of the project to that in the construction of the Panama Canal.

Division of War Minerals Supply Formed for Survey of Mineral Industries

Effective May 1, a division of war minerals supply was established in the Bureau of Mines. The new division has been charged with responsibility for matters relating to the supply of strategic minerals involved in war plans of the government, the maintenance of a proper balance of trade among the mineral industries of the nation and such related duties as may from time to time be assigned to it. H. S. Mulliken, who has for some time acted as special assistant to the director of the bureau, has been given charge of the work of this division.

The division will co-operate with the General Staff of the War Department, the United States Geological Survey, and a special committee of the A.I.M.E. in the proposed study of sources of supply and potential production of certain especially selected war minerals.

The head of the division will serve as chairman of the committee on strategic minerals of the economic liaison committee. He has further been placed in administrative charge of all activities in the production of helium that may devolve upon the Bureau of Mines, and will serve as one of the bureau's representatives on the army and navy helium board.

Bureau of Foreign and Domestic Commerce Will Establish Chemical Commodity Section

A commodity division which will specialize on the export problems of chemical industries will be set up in the Bureau of Foreign and Domestic Commerce of the Department of Commerce on July 1. This division will be comparable to the special services inaugurated last year in the interest of cotton and cotton goods, electrical goods, industrial machinery, lumber, paper and paper products and other export industries.

It was the intention a year ago to organize a chemical division, but it developed that there were numerous other industries in which the desire for this government effort was greater. It has been found, however, that while the more highly organized chemical companies are not greatly interested in receiving such assistance as the chemical commodity division could furnish, the smaller manufacturers are very much interested in obtaining this type of service. It will furnish them with much information which they could not attempt to gather for themselves.

No chief for the chemical division has been decided upon as yet, but an announcement is expected in the near future.

New Jersey Chemical Society Meeting

At a meeting of the New Jersey Chemical Society in Newark, N. J., May 8, J. F. Norris, professor of organic chemistry at Massachusetts Institute of Technology, spoke on "Recent Developments in Organic Chemistry." Prof. Norris discussed organic catalysts and other important industrial developments in the science, emphasizing the importance of pure research.

D. M. Goetschius, of the Standard Chemical Co., Pittsburgh, Pa., was scheduled to speak on "The Alpha Particle and Related Phenomena," but was prevented by sickness from attending.

Personal

Earl D. Babst, president of the American Sugar Refining Co., was the guest of honor at a dinner given at the Southern Hotel, Baltimore, Md., on May 5, in recognition of the completion of the company's new plant in this city. Governor Ritchie and Mayor Broening were among the prominent guests.

Baltzar De Mare, metallurgist and more recently steel superintendent for the Midvale Steel & Ordnance Co. for approximately 20 years, now has been appointed general manager of the Union Electric Steel Co., Carnegie, Pa.

Dr. Paul M. Giesy, formerly with the Calco Chemical Co., Bound Brook, N. J., is now research chemist with E. R. Squibb & Sons, at their Brooklyn, N. Y., plant.

Paul F. Holstein is now associated with the Buffalo Foundry & Machine Co. as its representative in Chile.

Charles O. Lavett has resigned his position as engineer of tests and field erection with the Buffalo Foundry & Machine Co. Mr. Lavett was in active charge of the research laboratory for this company and has been responsible for considerable of the development in "Buflovak" drying and evaporating apparatus. He has been with the company for about 15 years.

F. G. Liljenroth, of Stockholm, Sweden, formerly with E. I. du Pont de Nemours & Co., has just visited the United States.

William J. Priestley, formerly steel superintendent, naval ordnance plant, South Charleston, W. Va., has been appointed works manager, Pittsburgh Crucible Steel Co., Midland, Pa., succeeding H. P. Barnard, resigned, and has assumed his new duties. Prior to going to the naval ordnance plant, Mr. Priestley was a division superintendent at the Lehigh plant of the Bethlehem Steel Co. He was graduated from Lehigh University, class of 1908.

Robert C. Stanley, formerly first vice-president of the International Nickel Co., was recently elected president. Mr. Stanley has ordered a reorganization of personnel, involving as its chief feature a new department of development and research with headquarters at 67 Wall St., New York City. This department will be under the direction of A. J. Wadhams as manager. Associated with him will be Paul D. Merica, director of research.

R. T. Stull was relieved of the superintendency of the ceramic experiment station of the Bureau of Mines at Columbus, Ohio, May 1, and made supervising ceramist for the bureau as a whole. He will act under the direction of the chief mineral technologist and will have supervision in technical matters in ceramics and such related investigations of non-metallic minerals as may from time to time be assigned to him. Mr. Stull will have administrative as well as technical supervision of field work in the kiln investigation carried out in co-operation with the four heavy clay products associations, including the laboratory car "Holmes" and its crew. He will make his headquarters at Columbus, Ohio, but his services will be fully available for consultation by all branches of the bureau concerned with ceramics. George A. Bole has been designated acting superintendent of the Ceramic Experiment Station at Columbus, Ohio.

C. K. Williams, head of C. K. Williams & Co., Easton, Pa., manufacturers of paints and varnishes, has been elected a member of the committee of manufacturers of the Philadelphia sesquicentennial by Mayor Moore.

Obituary

Thomas S. Doherty, manager of the Delaware Chemical Engineering Co., of Wilmington, Del., died at his residence May 1. He was 67 years of age.

Henry Marion Howe, dean of American metallurgists, passed away Sunday, May 14, after a protracted illness. A biographical notice will be published in a later issue.

William Shepard Manning, Jr., assistant general manager of the Solvay Process Co., Syracuse, N. Y., committed suicide May 8. He suffered from insomnia and had just returned from a health resort on the Hudson River, where he had been for 3 weeks.

Edward Menge, of East Liverpool, Ohio, former president of the National Brotherhood of Operative Potters, died at his residence, April 30, after an illness of about a year's duration. He is survived by his wife and one son.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Overcapacity, Overproduction and Overcompetition

Sydney Anderson, the chairman of the joint commission of agricultural inquiry, has given us his opinion that there are at least three basic difficulties that are undermining business progress. He lists these in three words—overcapacity, overproduction and overcompetition. Others may differ with the distinguished investigator as to the relative importance of these underlying problems, but certainly they are worthy of our very careful consideration.

Overcapacity is a subject which has had the attention of the chemical industries many times within the past few years. Only recently in these columns we have had occasion to point out the difficulties of gaging productive capacity in terms of our distant mental concept of pre-war production. Such a starting point for appraising our industries fails to take account of the normal increase in the volume of manufacturing. This over a long period of years has been shown to average almost 4 per cent each year. In other words, if business had followed its normal and ordinary trend, our productive capacity today would be at least a third greater than in 1913.

Perhaps in the aggregate we have not materially exceeded this figure, but many individual industries have been extended far beyond their normal limits. No less an authority than Walter Renton Ingalls is responsible for the statement that in a part of our industrial field we now have an excessive capacity varying from 50 to 100 per cent. That this applies with particular emphasis in the chemical and metal industries, there can be no doubt. Here military demands of a stupendous character were followed by a post-war boom and an artificial and overdeveloped export trade. Naturally the period of readjustment and deflation has been most trying in these industries and there has been a tendency to cling to capacities far in excess of any possible demands.

The second problem cited by Mr. Anderson is perhaps not so evident. Production today is far beneath the normal, although probably no farther than is the present consuming capacity. But it is the constantly recurring surpluses that interrupt our progress and result in unpleasant situations such as the one from which industry is just now emerging. Overproduction is the natural sequence of overcapacity, although not necessarily so. Rather it is because in a highly specialized division of labor and industry it is impossible quickly to adjust production to the changing requirements of consumption. As the saturation points are exceeded for the individual commodities, surpluses pile up and industry suffers. The consumers' gains by the lower prices are more than swallowed up in the resulting unemployment and industrial stagnation.

In the minds of some of our legislators there is no such evil as overcompetition, which has been listed as the third of our underlying problems. The business man, however, who has witnessed its destructive effects is likely to regard it as the most serious of the three. The very commendable desire to make two chain stores grow where but one grew before is often the beginning of a process which when carried to its extremes results in price cutting and other demoralizing business practices. It is in the highly competitive situation especially such as follows a period of overproduction, that most of the losses of industry are incurred.

It is scarcely fair to list these industrial ailments without some mention of the palliative measures which are already being undertaken. Business men, economists and government officials are giving serious thought to these problems. The National Foreign Trade Convention which met last week in Philadelphia has tried to show that through the development of international commerce we can provide an outlet for the products of our overbuilt industries. Secretary Hoover and his co-workers in Washington have attempted to provide accurate statistics of production and consumption in the belief that through their use industry can avoid the constantly recurring peaks and valleys of the business cycle. And finally we have the recent impetus given to the study of the scope and activities of the trade associations—a development which is throwing new light on the meaning of competition and its relation to business conditions.

Thus the three "overs" of industry are being studied from many different angles and probably no small part of the present gradual improvement in business is directly traceable to the cumulative effects of such fundamental thinking.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

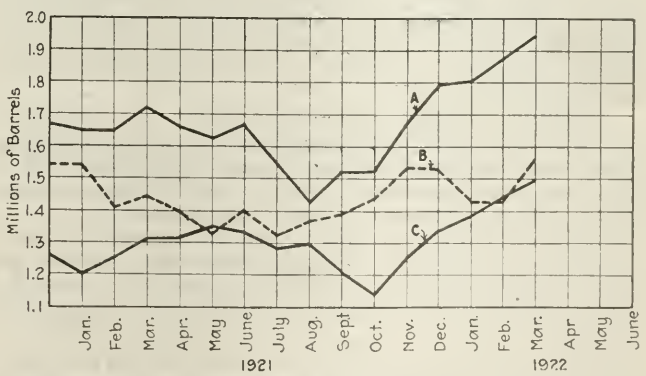
This week	**160.20**
Last week	159.77
May, 1917	222
May, 1920	279
April, 1918 (high)	286
April, 1921 (low)	140

This week's index number shows a net gain of 0.43 due primarily to the increase in the price of crude cottonseed oil, caustic soda and saltcake. Slightly lower prices were reported for 66 deg. sulphuric acid, ammonium sulphate, caustic potash and aniline oil but the cumulative effect was not sufficient to offset the upward tendency of the index number.

Record Petroleum Production During March and April

During the month of March the petroleum industry set new high records in all directions. The production of crude oil totaled 46,916,000 bbl., which may be compared with the previous record output last January of 43,141,000 bbl. Consumption of crude oil amounted to 48,840,000 bbl., which makes it the highest on record. The previous maximum was in August, 1920, with a total of 48,732,000 bbl. Imports amounted to 14,004,000 bbl. which have been exceeded only once—viz., in November, 1920, with a total 14,136,000 bbl.

The huge production, combined with heavy imports, re-



MONTHLY CHANGES IN DAILY AVERAGE RATE OF—

(*A*) Domestic production of petroleum plus imports of crude oil.
(*B*) Estimated consumption of domestic and imported petroleum.
(*C*) Domestic production (petroleum transported from producing properties).

(Data from U. S. Geological Survey)

sulted in an increase of 12,000,000 bbl. in stocks, in spite of the heavy consumption. Stocks amounting to 220,233,000 bbl. are far in excess of anything heretofore recorded.

Apparently, however, there will be a slight recession during April. The American Petroleum Institute's estimated daily average for the 4 weeks of that month have been as follows:

	Week Ended			
	April 8	April 15	April 22	April 29
Oklahoma	365,000	363,200	363,500	374,350
Kansas	81,500	81,000	82,200	82,000
North Texas	52,100	52,300	52,250	52,300
Central Texas	168,150	153,800	149,950	149,300
North Louisiana and Arkansas	141,200	128,450	120,150	118,750
Gulf Coast	114,100	114,950	111,650	114,600
Eastern	115,000	115,000	118,000	118,500
Wyoming and Montana	70,900	72,150	69,050	71,900
California	325,000	330,000	330,000	330,000
Total	1,432,950	1,410,850	1,396,750	1,411,700

Synthetic Organic Chemicals

The striking expansion that has occurred during the last 4 years in the manufacture and distribution of synthetic organic chemicals for scientific and industrial research is evidenced by the fact the recent price list of the Eastman laboratories contains the names of approximately 1,300 different compounds. One interesting innovation in the present list is the inclusion of the melting points, boiling ranges and other purity criteria for the larger share of the chemicals. Such data are of special value to most of the users of these products and should have the effect of encouraging improved quality and higher standards of purity in this line of chemical manufacture.

The New York Market

New York, May 15, 1922.

The chemical market has been noticeably steady during the past week and aside from slightly easier prices for one or two minor commodities, the general list has undergone no important declines. One of the leading features of the week's trading was the pronounced interest in solid caustic soda for export. Standard brand material is extremely scarce and outside brands have brought $3.80 per 100 lb. for July shipment. The demand for oxalic acid has increased materially and the market was sharply advanced on spot and at the works by leading factors. Prussiate of soda has recorded an additional advance, with the consumers showing an increased interest. Other prussiates remain in the same firm position as previously reported. Bichromates have been neglected of late and both the soda and potash salts are slightly easier on spot. Barium chloride has eased off somewhat and prices were a shade lower in several directions. Carbonate of potash has been in fair demand. Copper sulphate is still very active, with prices quite firm on prime material. Tin oxide was reduced 2c. per lb. by makers. A slightly easier feeling was noted on caustic and permanganate of potash.

General Chemicals

Arsenic—Small-lot trading is about the best way to characterize this market. Prominent factors quote spot and prompt shipment of prime white powdered at 7@7½c. per lb. The red variety is quoted around 11½@12c. per lb. The general demand is not up to the expectations of the manufacturers.

Aluminum Sulphate—The demand for the commercial variety has improved considerably and several large tonnage sales have been made by first hands at $1.50 per 100 lb. The iron-free is quoted at $2.50 per 100 lb. Imported material is quoted at the same price as the domestic.

Bichromate of Potash—Spot goods are offered at 9¼@10c. per lb. by second hands, while producers quote 9¾@10c. per lb. for prompt shipment. Trading is generally quiet in this item, with first hands getting practically all of the passing business.

Bleaching Powder—Leading sellers are holding the market at $1.60 per 100 lb., f.o.b. works, in large drums. Export containers have been sold at lower levels and $1.40 per 100 lb. was quoted in some directions. Trading is generally quiet.

Caustic Soda—There has been no let-up from the firm position of this product. The export demand is extremely strong, with only a few odd lots available for early shipment. Prices are quoted around $3.90 per 100 lb. f.a.s. Outside brands can be bought a shade under this price, although some factors are reported sold up through July. Quotations at the works for contracts remain quotably unchanged.

Copperas—Producers offer prime green crystals at $20 per ton. The demand is rather quiet in all directions and the market has uncovered no features of interest.

Citric Acid—There were sales recorded at 45@46c. per lb., depending upon the quantity and seller. The demand is only moderate. Offerings were not heavy and leading dealers are looking for a stronger market with the coming hot weather.

Fluoride of Soda—Producers quote 9c. per lb. as the low figure for this material and up to 10c. per lb. for smaller quantities. The market is about up to the expectations of the manufacturers, with small lots featuring.

Oxalic Acid—Prices have been sharply advanced on this product. The best quotation heard late in the week was 13c. per lb. f.o.b. works. Spot goods were quoted at 13¾@14c. per lb. Several large sales were reported during the advance and the general demand has shown considerable improvement.

Prussiate of Soda—Higher prices have been established for this material and the market closed firm at 18¾c. per lb. on spot. Offerings have noticeably decreased and this has given additional strength to the item. Shipment material is higher, with sellers asking 18½@18¾c. per lb.

Vegetable Oils

Linseed Oil—The market for this commodity was very firm in the early trading, but was rather quiet during the latter part of the week. Leading crushers named 90c. per gal. for raw oil, in carload lots, shipment over the next 4 months. Oct.-Nov.-Dec.-contracts ranged from 92@93c. per gal. Large consumers seem to have filled requirements for nearby oil and it is believed that trading may show some brief signs of weakness. Foreign oil sold at 83c. per gal., duty paid, May shipment.

Castor Oil—Trading was somewhat quieter although prices ruled steady in sympathy with the strong seed market. Quotations remained unchanged on both the AA and No. 3 grades.

Coconut Oil—Business during the interval has been less active than in the previous week, but there were several inquiries in the market for forward delivery oil and the general condition was somewhat firm. Ceylon type oil, May-June shipment from the coast, in sellers' tanks, was offered at 7½c. per lb., May-June shipment from N. Y. at 8c. per lb., sellers' tanks. Ceylon in barrels, carload lots, sold at 8¾c. per lb.

Palm Oils—The market for lagos oil was dull and prices were unsettled. There were sellers at 7⅛@7¼c. per lb., c.i.f. N. Y. Niger oil was quoted at 6⅛@6¼c., per lb., c.i.f.

The St. Louis Market

St. Louis, May 11, 1922.

The volume of business transacted for the first 10 days of this month has been very gratifying, and dealers expect that there will be a material increase in the demand for industrial chemicals as well as for fine chemicals during the next few weeks.

Prices generally are firm and advances have far exceeded the number of declines for some few weeks. One of the chief reasons for the firming up of the market is that the foreign competitor has found it necessary to increase his prices, thereby eliminating price disturbances.

Alkalis

Caustic soda remains normal in price, with a routine demand, no great volume of business having been reported. *Soda ash* has been quoted in this market as low as $2.15 per 100 lb. in bags, $2.35 per 100 lb. in barrels, though the prevailing price is around $2.20 and $2.40 respectively. Carload prices range around $2 per 100 lb. f.o.b. purchaser's

door. *Sal soda* continues to maintain a steady price with a good demand. *Sodium bicarbonate* is being handled rather recklessly by jobbers in this market, prices ranging from $2@$2.25 per 100 lb. in 5-bbl. lots.

General and Special Chemicals

One of the heavy *mineral acid* manufacturers reports a very good undertone in spite of the fact that the steel mills are greatly hampered in their operations by the present coal strike, and if it were not for this hindrance the acid market today would be a booming one. Prices are firm with no surplus stocks. In our last report it was stated that an advance in *citric acid* would not prove surprising, but to date this increase has not taken place. However, we believe that an advance in price ought to come, because there is a scarcity of stocks and foreign goods are now being held at a higher figure. Furthermore, there will be a much greater demand in the immediate future from the soft drink manufacturers. *White arsenic powder* is firm at 6½@7c. f.o.b. New York, with the demand very quiet and a scarcity of stock. *Solid calcium chloride* is now being quoted in 1- and 5-drum lots at $1.60 per 100 lb. f.o.b. St. Louis, with a differential of 5c. per 100 lb. in lots of 5 to 10 drums; the granular at $1.90 per 100 lb. f.o.b. St. Louis in lots of 1 to 6 drums, with a differential of 5c. per 100 lb. in lots of 7 to 15 drums. *Carbon bisulphide*, being one of the chemicals used as an insecticide, is commanding a prominent position and undoubtedly will continue to hold same for some time. *Glycerine* is a weak sister on the market at the present. The new price of 15c. has not stimulated buying and 14½c. has been quoted on firm orders. *Zinc sulphate* is now holding at $2.85@$2.90 per 100 lb. f.o.b. St. Louis and the market is stiffening in keeping with the advance in *zinc spelter*, which has increased approximately $15 per ton within the last 60 days. It is interesting to observe that for the first time since the close of the World War there has been a large demand for zinc from European countries. There is also a good demand for *zinc dust* originating from the dye manufacturers, and prices on this commodity are also stiffening in line with the spelter.

Vegetable Oils and Naval Stores

Linseed oil has recovered its full strength and producers are in a firmer position today than they have been for some time. On April 13 linseed oil was reported in this column at 86c. basis raw oil; today it is quoted at $1.07. *Turpentine* has gone as low as 85c. and as high as 96c. *Castor oil* has advanced ½c. and now is in good demand at 12¾c. in quantities of 200 gal., with an advance of 1c. for less quantities.

The Iron and Steel Market

PITTSBURGH, May 12, 1922.

The monthly report of steel ingot production was awaited with unusual interest, as estimates of the producing rate could not be made in April with the usual facility, since the coal strike caused curtailment of pig iron and therefore of steel production at some points, while there were increases at other points, not affected by the coal strike. Estimates made in these reports recently, that ingot production was running at a rate between 36,000,000 and 38,000,000 tons a year, are confirmed. From the report of production in April on the thirty companies that make monthly returns it may be computed that the average rate during April was 36,600,000 tons, with a probable error of a few hundred thousand tons. In January, February and March there were continuous and sharp increases, and March, with an average rate of 32,500,000 tons, as shown by the report for the month, probably opened with a 30,000,000-ton rate and closed with a 35,000,000-ton rate. Thus production must have increased somewhat during April, despite the coal strike, the gains overbalancing the losses.

Mills Adapting Themselves to Conditions

The mills and furnaces affected by the coal strike have done good work in promptly adapting themselves to the suddenly imposed condition. Coal has been bought in various markets, some of them quite distant, Kentucky figuring prominently. Not the least spectacular of the unusual movements is the bringing of beehive coke from Sloss ovens in Alabama to Steel Corporation furnaces in Ohio. At several steel plants piles of pig iron, regarded a few months ago as a drug on the market, are being used. The steel works in the Pittsburgh district are certainly not reduced to extremities, for there has not been a purchase of heavy melting steel by a consumer in the district for nearly 2 weeks, although the price done in the last purchases, $17.50, is far from prohibitive.

Prospects are that steel production, on the whole, will increase somewhat in the next few weeks. There is no sign that it will decrease from stocks of coal being exhausted, for the steel industry is obtaining, by various means, a great deal of coal. The Mingo plant of the Carnegie Steel Co., which was closed early in April, is resuming operations. The full rating of the plant is 600,000 tons of ingots a year.

Steel Market Strong

The steel market, as a market, is very strong, and is altogether in favor of sellers. Consumers who 2 months ago were reserved about buying are now urging the mills to accept additional orders and contracts. In some instances third quarter and even fourth quarter contracts are offered, the mill to name prices later. Premiums for early deliveries are occasionally offered.

Not a few of the independents' mills have advanced their asking prices and are able to make some sales at the advances. The Steel Corporation has made no regular advances, but in bars, shapes and plates is getting a slightly higher average than a week or two ago. In these products the tonnage and character of specifications have something to do with the price.

The market is still quotable at the regular prices named in the past few weeks, but in most products there are some sales at higher prices, in the case of less desirable orders or of prompt deliveries. Regular prices are: Bars, shapes and plates, 1.50c.; bands, hoops and hot-rolled strips, 2c.; standard steel pipe, 71 per cent basing discount; blue annealed sheets, 2.40c.; black sheets, 3.15c.; galvanized sheets, 4.15c.; automobile sheets, 4.50c.; tin plate, $4.75; plain wire, 2.25c. On nails there are two prices, the Steel Corporation's price of $2.40 and the independent price of $2.50.

Sheet bars are now quotable at $35, there being no possibility of less being done, while there are no regular offerings even at $35. At the March price of $29 sheet mills did not buy more than enough to cover their sales of sheets at old prices, based on 3c. for black, hence there is a disposition to ask more than the present market of 3.15c., with sheet bars $6 a ton higher.

Coal and Coke

Connellsville coal has advanced sharply, chiefly on account of Eastern buying, and is now quotable at $3.25@$3.50 for steam grade. Connellsville coke is quotable at $6.50 for furnace and $6.75 for foundry, with limited offerings and limited demand.

One or two sales of basic pig iron are reported at $25 valley, or $1 over last week's nominal quotation. One merchant furnace now quotes this price, not being entirely out of the market as formerly, and names $26 on bessemer. Foundry remains quotable at $24. Inquiry is quite limited.

Steel Corporation Tonnage

With only trifling exceptions the Steel Corporation's unfilled obligations decreased month by month from 11,118,468 tons on July 31, 1920, to 4,141,069 tons on Feb. 28, 1922. In some months early in 1921 the decrease in a month was almost equal to the shipments, there being scarcely any bookings. Last March the unfilled obligations increased by 353,079 tons, while April showed an increase of 602,769 tons. The March increase represented 25 per cent of a month's capacity, while the shipments were about 65 per cent, making the bookings about 90 per cent of capacity. In April shipments were about 70 per cent of capacity and the increase in unfilled tonnage 45 per cent, making the bookings about 115 per cent. The bookings are chiefly for relatively early delivery, there being not much construction work involving very extended deliveries.

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.15 — .16
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.75 — .85
Benzoic acid, U.S.P.	lb.	.65 — .70
Benzoate of soda, U.S.P.	lb.	.55 — .57
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00½
Beta-naphthol, sublimed	lb.	.50 — .55
Beta-naphthol, tech	lb.	.25 — .27
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.53 — .55
Cresylic acid, 95-97%, dark, in drums	gal.	.48 — .50
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.65 — .70
Dimethylaniline	lb.	.36 — .38
Dinitrobenzene	lb.	.22 — .25
Dinitroclorbenzene	lb.	.22 — .24
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .65
H-acid	lb.	.85 — 1.00
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.09 — .11
Monoethylaniline	lb.	1.05 — 1.25
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½— .07
Naphthalene, balls	lb.	.08 — .08½
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	2.50 — 2.60
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.70 — .75

Ortho-nitro-toluene	lb.	.12 —	.15
Ortho-toluidine	lb.	.16 —	.20
Para-amidophenol, base	lb.	1.25 —	1.30
Para-amidophenol, HCl	lb.	1.30 —	1.35
Para-dichlorbenzene	lb.	.14 —	.16
Paranitroaniline	lb.	.75 —	.77
Para-nitrotoluene	lb.	.60 —	.70
Para-phenylenediamine	lb.	1.50 —	1.55
Para-toluidine	lb.	1.05 —	1.15
Phthalic anhydride	lb.	.35 —	.38
Phenol, U. S. P., drums	lb.	.14 —	.15
Pyridine	gal.	1.75 —	2.75
Resorcinol, technical	lb.	1.30 —	1.35
Resorcinol, pure	lb.	1.75 —	1.80
Salicylic acid, tech., in bbls.	lb.	.25 —	.25½
Salicylic acid, U. S. P.	lb.	.26 —	.26½
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.25 —	.28
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.10 —	.12
Sulphanilic acid, crude	lb.	.24 —	.26
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	.28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal.	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	....

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

LITTLE ROCK—The Rose City Cotton Oil Mill Co. is planning for the rebuilding of the portion of its plant, recently destroyed by fire, with loss estimated at about $45,000. Alfred Kahn is general manager.

FORT SMITH—The Twin City Glass Co. has commenced the construction of its proposed local plant, with main building 50x100 ft., to be equipped for the manufacture of bottles and other glass containers. It is proposed to commence production late in June, giving employment to about 100 operatives. Harry Hart is president.

California

GLENDALE—The International Chemical Products Co., 710 East Broadway, has awarded a contract to the R. L. Kent Co., 130 South Brand Blvd., for the construction of a first unit for a new plant on property recently acquired on West Colorado St., comprising about 2½ acres of land. The structure will be 2-story, 25x100 ft., and will be supplemented with other units at a later date. The plant will be equipped for the manufacture of special printing inks and kindred products. George W. Strang is general manager.

Connecticut

ELMWOOD—The Park Brick Co., Elmwood, near Hartford, is considering plans for the rebuilding of its plant, destroyed by fire April 29, with loss approximating $150,000, including equipment.

Idaho

CŒUR D'ALENE—The Callahan Zinc-Lead Co., 61 Broadway, New York, N. Y., is reported to be planning for the purchase of local property, for which negotiations are now under way, for the establishment of a new plant. The company has secured options on the property of the Marsh Mining Co., in the Hecla district, and proposes extensive operations in this section.

Illinois

ROCK ISLAND—The Service Rubber Co., 401 Central Trust Bldg., has plans nearing completion and will take bids late in May for the construction of a new 3-story plant, 60x300 ft., on local site, estimated to cost about $100,000 with machinery. Cervin & Horn, 311 Safety Bldg., are architects. J. T. Crowley heads the company.

Indiana

ELWOOD—The Macbeth-Evans Glass Co., Chamber of Commerce Bldg., Pittsburgh, Pa., is completing plans for extensions and improvements in its local plant to cost about $35,000. Work will be commenced at an early date.

GARY—The National Tube Co., Frick Bldg., Pittsburgh, Pa., a subsidiary of the United States Steel Corp., has plans nearing completion for the construction of its proposed new plant on the Lake Front, Gary, recently authorized by the parent organization; work will begin at an early date. The new steel mill will consist of a series of buildings, estimated to cost close to $15,000,000, with machinery. William B. Schiller is president; R. C. Patterson is chief engineer in charge.

Iowa

MARSHALLTOWN—The City Council has preliminary plans under way for the construction of a new filtration plant at the municipal waterworks. O. G. Herm is city engineer.

Louisiana

STERLINGTON — The Federal Petroleum Co., Monroe, La., has acquired property on the Ouachita River, Sterlington, for the construction of a new assembling and distributing plant. The company purposes extensive operations in this vicinity, and will develop a large refined oil output.

MONROE—The Southwest Pulp & Paper Co., 342 Madison Ave., New York, N. Y., will take bids during June and July for considerable equipment for installation at its proposed new plant on the Monroe-Columbia Highway. The initial works will aggregate about 70,000 sq.ft., and will be equipped for an output of approximately 100 tons of refined pulp per day. A power plant will also be erected. The new mill is estimated to cost close to $250,000. Joseph G. Mayo is president and managing director, with headquarters at 206 Broadway, Norwich, Conn.

Maryland

EASTON—The New Brick & Tile Co., Moreland Bldg., recently organized with a capital of $50,000, will take bids at once for the construction of its proposed new 1-story plant on local site for the manufacture of brick, drain tile and other burned clay products. It will cost about $42,000, including equipment. J. Fletcher Clark is secretary and treasurer.

BALTIMORE—The Baltimore Gas Appliance & Mfg. Co., Bayard and Hamburg Sts., is considering plans for the construction of an addition to be equipped as a porcelain-enameling department. H. W. Hunter is president.

Massachusetts

CAMBRIDGE—The Whittemore Brothers Corp., Albany St., has awarded a contract to the Scully Co., East Cambridge, for the rebuilding of the portion of its polish manufacturing plant, recently destroyed by fire. The new structure will cost approximately the amount of the fire loss, $65,000, and work will be commenced at once.

Michigan

BENTON HARBOR—The City Council has plans under way for the construction of a new filtration plant at the municipal waterworks. Pearce, Greeley & Hansen, 39 West Adams St., Chicago, Ill., are engineers.

DETROIT—The Detroit Sand Lime Brick Co., 507 Vinton Bldg., will soon commence the construction of its proposed new plant on property lately acquired on the Oakwood side of the River Rouge, comprising about 16 acres of land. The main structure will be 125x400 ft. A portion of the machinery installation will be of special type. William Niemann is secretary and treasurer.

Mississippi

WOODVILLE—The Dampf & Morgan Co. has acquired the property of the Woodville Oil Mill, and plans to convert the structure for a paper mill. Plans are being prepared for a number of improvements and alterations.

New Jersey

TRENTON—Lenox, Inc., Mead St., manufacturer of fine chinaware, has awarded a contract to the Karno-Smith Co., Trenton, for the erection of a 1-story building at its plant.

PASSAIC—The Paterson Parchment Paper Co., 6th St., has commenced the erection of a new 2-story plant extension, 40x120 ft., to be used for general operating service. It will cost about $50,000. The Solomon-Abbott Co., 175 Fifth Ave., New York, N. Y., is engineer.

PATERSON—Fire, May 1, destroyed a portion of the plant of the Olive Oil Soap Co., 85 Fulton St., with loss reported in excess of $100,000, including building, equipment and materials.

New York

POUGHKEEPSIE—The Corrugaed Rubber Co., 25 West 43rd St., New York, will take bids at once for the erection of the first unit of its proposed plant in the Fairview section, Poughkeepsie, to be 1-story, 60x200 ft., and estimated to cost about $90,000, including machinery. W. L. Fairchild is general manager. W. J. Beardsley, 49 Market St., Poughkeepsie, is architect.

NEW YORK—The American Smelting & Refining Co., 120 Broadway, is arranging an appropriation of $750,000, for extensions and betterments at its Colorado properties, including the installation of new equipment. The work will include the construction of an addition to the smelting plant at Durango, to cost approximately $250,000, and improvements in the Rawley properties near Salida, to cost $100,000.

OLEAN—The Vacuum Oil Co., 61 Broadway, New York, will commence the immediate erection of the superstructure at its plant additions at Olean, comprising a number of buildings, estimated to cost about $500,000, including equipment. The White Construction Co., 95 Madison Ave., has the building contract.

BROOKLYN—A. Aron, 335 Johnson Ave., has awarded a contract to Thomas Drysdale, 250 Baltic St., for the erection of a 3-story fat rendering plant, 50x70 ft., estimated to cost about $25,000. Joseph Himmelsbach, 136 Liberty St., New York is engineer.

ENDICOTT — The Binghamton Limestone Co., care of the Kellogg-Jones Co., O'Neill Bldg., Binghamton, has preliminary plans under way for the erection of a new plant on site selected at Endicott, for the manufacture of brick and kindred products.

North Carolina

CHARLOTTE—The Virginia-Carolina Chemical Co., Richmond, Va., has plans under way for the erection of a new local plant for the manufacture of fertilizer products.

Ohio

SALEM — The Sumatra Rubber Specialty Co., recently organized, has acquired a local building and will install machinery at once for the manufacture of rubber goods of various kinds.

YOUNGSTOWN — The Newton Steel Co., manufacturer of steel sheets, etc., is considering tentative plans for the construction of a series of new sheet mills, comprising about 6 individual units, estimated to cost about $750,000 with machinery.

LANCASTER—The Fairfield Glass Co. has preliminary plans under consideration for the construction of a new local plant for window glass manufacture, consisting of a number of buildings, estimated to cost in excess of $2,000,000. Leopold Hambourg is general manager.

CLEVELAND—The Industrial Fibre Co. of America, Waldorf Ave., S. W., and West 98th St., has filed plans for the erection of a 3-story and basement addition, 84x100 ft., estimated to cost about $60,000. Work will be placed under way at once.

Oklahoma

SHIDLER — The Phillips Petroleum Co., Bartlesville, has work nearing completion on a new gasoline-extraction plant, estimated to cost close to $1,000,000, and forming one of the largest works of its kind in the country. Operations will be commenced in the first 13 units at an early date; more units will be constructed at a later date, with installation to comprise gas engines, air compressors, etc.

Pennsylvania

PITTSBURGH—The Fleischmann Co., 701 Washington St., New York, N. Y., has acquired property at Western and Allegheny Aves., 75x192 ft., for a consideration of $25,000, as a site for the erection of its proposed new yeast-manufacturing plant, to be 3-story and estimated to cost about $100,000, including equipment. It is planned to commence construction early in the summer.

PHILADELPHIA—The Powers-Weightmann-Rosengarten Co., Moore and 35th Sts., manufacturer of chemicals, has filed plans for the erection of an addition to its plant, 2-story, 42x80 ft., estimated to cost about $16,000.

NEW CUMBERLAND—The New Cumberland Paper Co. will commence the immediate erection of a new 1-story plant on local site, 60x90 ft. The building contract has been let to Harry Hollacher, New Cumberland.

PHILADELPHIA — The Nustone Products Corp., 3450 Richmond St., manufacturer of sanitary products, ware, etc., has awarded a contract to John M. Yardley, 1716 Samsom St., for the erection of a new 1-story plant, 140x192 ft., on Schiller St., near Allen Ave. Work will be commenced at once. Ritter & Shay, North American Bldg., are architects.

Tennessee

GALLATIN—The City Council has plans under way for the construction of a new

filtration plant at the waterworks. W. H. Blyce, First National Bank Bldg., is consulting engineer.

Texas

LUBBOCK — The Quanah Cotton Oil Co. has completed plans for the first buildings for its new cotton oil mill, and will commence erection at an early date. The plant will be of 4-press type. Other units will be constructed at a later time.

MARSHALL—The Marshall Brick Co. will commence the immediate installation of new machinery at its plant for the manufacture of dry-pressed brick, forming a new department for this branch of production. The initial capacity will be about 20,000 bricks per day, and which will be increased at a later date.

SHERMAN—The oil refinery of the Buffalo Oil & Producing Co., South Sherman, has been acquired by F. M. Thompson, C. C. Mayhew and associates, all of Sherman, at a receiver's sale. The new owners will organize a company and operate the plant. A number of improvements will be made.

Virginia

NORFOLK—The Robertson Fertilizer Co. has awarded a contract to the Chemical Construction Co., Charlotte, N. C., for the rebuilding of its plant at Money Point, destroyed by fire several months ago. Work will be placed under way at once.

Washington

KENNYDALE—The Republic Creosoting Co. is arranging for the immediate rebuilding of the portion of its plant on Lake Washington, recently destroyed by fire. F. C. Powell is general manager.

West Virginia

THOMAS—The City Council is planning for the installation of a new waterworks system, including a filtration plant. Bonds will soon be voted.

CHARLESTON — The Warner - Klipstein Chemical Co., comprising a recent merger of the Warner Chemical Co. and the E. C. Klipstein & Sons Co., has plans under way for extensions in its plant for considerable increase in capacity. F. J. Kaufman is resident manager.

Capital Increases, etc.

THE CENTRAL GLASS WORKS, INC., Charleston, W. Va., has filed notice of increase in capital from $500,000 to $600,000.

THE SPECIALTY RUBBER WORKS, Hackett St., Newark, N. J., has filed notice of change of name to the Goodyear Rubber Mfg. Co.

THE PLANTATION CONSOLIDATED OIL CORP., Bowling Green, Ky., has filed notice of increase in capital from $150,000 to $350,000.

THE UNION OIL CO. OF CALIFORNIA, Union Oil Bldg., Los Angeles, Cal., is disposing of a bond issue of $10,000,000, the proceeds to be used for general operations, financing, expansion, etc. W. L. Stewart is president.

THE SIZER STEEL CORP., Buffalo, N. Y., has arranged for a bond issue of $1,250,000, the proceeds to be used for general expansion, operations, etc. The company has recently acquired the plant of the Hammond Steel Co., Syracuse, N. Y. C. B. Porter is president.

THE NATIONAL ZINC CO., 61 Broadway, New York, N. Y., has filed notice of dissolution under state laws.

THE DIXIE BELL REFINING CO., Louisville, Ky., has filed notice of change of name to the Louisville Refining Co., to operate oil refineries.

THE AMERICAN WOODPULP CORP., 347 Madison Ave., New York, N. Y., has filed notice of increase in capital from $70,000 to $370,000.

THE HURRICANE IRON & MINING CO., Columbia, Tenn., has filed notice of increase in capital from $60,000 to $100,000.

COSDEN & CO., 120 Broadway, New York, operating oil refineries in the mid-continent field, Okla., has arranged for a preferred stock issue of $3,252,900, the proceeds to be used for general operations, expansion, financing, etc.

The receiver for the ZEE ZEE RUBBER CO., Yardville, N. J., is arranging for the sale of the plant of the company.

THE LAMBERSON JAPANNING CO., 2334 West Kinzie St., Chicago, Ill., has filed notice of increase in capital from $5,000 to $150,000.

The receiver for the STOCKTON RUBBER CO., Trenton, N. J., will dispose of the plant and property of the company.

New Companies

THE JOHNSON PRODUCTS CO., Newark, N. J., has been incorporated with a capital of $500,000, to manufacture celluloid specialties and other composition products. The incorporators are Frank E., Horace C., Jr., and Charles J. Johnson, 138 Paris St.

THE OVERBROOK GLASS BOTTLE CO., Jeannette, Pa., has been incorporated with a capital of $50,000, to manufacture glass products. S. H. Grimes, Jeannette, is treasurer.

THE ALLEN RUBBER CO., Boston, Mass., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture rubber goods. Charles Langmaid is president; and Max Laserson, Fabyan St., Dorchester, Mass., treasurer.

THE LINN PRODUCTS CO., 125 South Jefferson St., Chicago, Ill., has been incorporated with a capital of $35,000, to manufacture soaps, washing powders, etc. The incorporators are Robert White, Leon Hamburger and Perrin C. Miller.

THE GREENVILLE PAPER CO., Greenville, S. C., has been incorporated with a capital of $20,000, to manufacture paper products. J. W. Keys is president; W. S. Mills, vice-president; and J. C. Keys secretary, all of Greenville.

EUGENE SUTER & CO., INC., New York, N. Y., has been incorporated with a capital of $400,000, to manufacture chemicals, chemical byproducts, drugs, etc. The incorporators are Eugene Suter, F. Russell and H. C. Tomlinson, Jr. The company is represented by A. C. Coxe, Jr., 15 Broad St., New York.

GRUESSNER'S, INC., New Brunswick, N. J., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are Alexander and Anthony Gruessner, 4 French St., New Brunswick.

THE NAUGATUCK TIRE & RUBBER CO., Wilmington, Del., has been incorporated with a capital of $1,500,000, to manufacture automobile tires and other rubber products. The company is represented by the Corporation Service Co., Equiptable Bldg., Wilmington.

THE POPE CHEMICAL CO., Boston, Mass., has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. Nicholas DuVally is president; and A. B. DuVally, 57 Cambridge St., Boston, treasurer.

THE TEXAS-MEXICAN OIL AND REFINING CO., Lardo, Tex., has been incorporated with a capital of $125,000, to manufacture refined petroleum products. The company has preliminary plans under way for the construction of a refinery on local site. J. N. Galbraith is president; Miles T. Cogley, vice-president; and J. N. Galbraith, Jr., secretary, all of Lardo.

THE GIRARD PAINT CO., Girard, O., has been incorporated with a capital of $25,000, to manufacture paints, varnishes, etc. The incorporators are J. H. Drage and F. H. Bushong, both of Girard.

THE ALUMINO THERMIC CORP., 15 Exchange Place, Jersey City, N. J., has been incorporated with a capital of $300,000, to manufacture chemicals and chemical byproducts. The incorporators are Hugh G. Spilsbury, Charles H. Hunter and Merle I. St. John.

THE CENTURY PAPER CO., Indianapolis, Ind., has been incorporated with a capital of $30,000, to manufacture paper products. The incorporators are H. A. Rowley, W. N. Gillett and Robert W. Fleischer, all of Indianapolis.

THE OIL PRODUCERS REFINING CO., New Castle, Del., has been incorporated under state laws, with a capital of $40,000, to manufacture refined oil products. The incorporators are M. M. Toner, New Castle; G. H. Reed and R. L. Spurgeon, Wilmington, Del. The company is represented by the Corporation Guarantee & Trust Co., Land Title Bldg., Philadelphia, Pa.

THE ASHLEY-BEHRENS MFG. CO., 8370 Grand River Ave., Detroit, Mich., has been incorporated with a capital of $20,000, to manufacture waxes, varnishes and kindred products. The incorporators are G. Leon Ashley, Wilbur J. Behrens and Norman F. Thomssen.

THE MONITOR PAINT & CHEMICAL CO., 88 North St., Boston, Mass., has filed notice of organization to manufacture chemical specialties. John V. O'Donnell heads the company.

THE HARLAND OIL CO., Wilmington, Del., has been incorporated under state laws, with capital of $1,000,000, to manufacture petroleum products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE L. & P. DENNIS & SON CO., 926 Main St., Crisfield, Md., has been incorporated with a capital of $100,000, to manufacture fertilizer products. The incorporators are E. Benson Dennis, James H. Sterling and William M. Wooster.

THE PARAMOUNT PAINT & VARNISH CO., Brooklyn, N. Y., has been incorporated with a capital of $5,000, to manufacture paints, varnishes, etc. The incorporators are S., V. and M. Isaacs. The company is represented by Levinson & Feinsod, 277 Broadway, New York.

THE NATIONAL INK WORKS, INC., Camden, N. J., has been incorporated with a capital of $100,000, to manufacture ink and affiliated products. The incorporators are Edward F. Dennis, Edmund Kirkbridge and Joseph A. McHenry, Jr. The company is represented by Rudolph S. Ayers, 428 Market St., Camden.

THE AMERICAN ANILINE WORKS, INC., Philadelphia, Pa., has been incorporated with a capital of $25,000, to manufacture chemicals, dyes and kindred products. G. L. Armour, 455 West End Ave., New York, N. Y., is treasurer.

THE GARDINER-MCKINNES CO., New York, N. Y., has been incorporated with a capital $121,000, to manufacture chemicals, chemical byproducts, paints, etc. The incorporators are B. and G. N. Gardiner and J. P. Green. The company is represented by Phillips & Abery, 41 Park Row, New York.

THE LOCAL REFINING CORP., Oklahoma City, Okla., has been incorporated with a capital of $20,000, to manufacture refined petroleum products. The i corporators are M. H. Davis, R. L. Edwards and D. B. Richardson, all of Oklahoma City.

THE JACKSON MFG. CO., Trenton, N. J., has been incorporated with a capital of $150,000, to manufacture leather products. The incorporators are Maurice and Saul Black. The company is represented by Alexander Trapp, 147 East State St., Trenton.

THE CRESCENT CHEMICAL CO., Boston, Mass., has filed notice of organization to manufacture chemicals and chemical byproducts. The company is headed by Michael J. Cavanaugh and Frank E. Lanagan, 1041 Washington St., Boston.

THOMAS SEALY, INC., New York, N. Y., has been incorporated with a capital of $400,000, to manufacture chemicals, chemical byproducts, paints, etc. The incorporators are Thomas Sealy, W. J. Doyle and L. M. Vandolen. The company is represented by Pallister, Greene & O'Connell, 233 Broadway, New York.

THE RICHARDSON OIL CO., 102-104 South Front St., Quincy, Ill., has been incorporated with a capital of $50,000, to manufacture oil products. The incorporators are John T. and E. Dean Richardson, and James A. Johnson.

THE RUWART MFG. CO., Jefferson City, Mo., has been incorporated with a capital of $250,000, to manufacture leather products. The incorporators are Henry, Joseph E., and William Ruwart, all of Jefferson City.

THE PURITAN OIL & SOAP CO., Boston, Mass., has filed notice of organization to manufacture soaps, oils and affiliated products. Alfred Boggild, 215 Endicott St Boston, heads the company.

Industrial Notes

DWIGHT P. ROBINSON & CO., New York, announce that a contract has been awarded them for the construction of a building to accommodate American commercial exhibits at the Brazilian Centennial Exposition to be held in Rio de Janeiro beginning Sept. 7. The building, which will be the "unofficial" exhibit building, will be constructed of American materials as far as possible. It will be purely a commercial proposition, having no direct connection with the exhibition plans of the American Government under the appropriation of $1,00,000 made by Congress recently.

THE PFAUDLER CO., Rochester, N. Y., announces that on May 1 its New York office was moved to Room 1103, 8 West 40th St.

THE BETHLEHEM FOUNDRY & MACHINE CORP. announces that on May 1 it moved to Room 1716, Grand Central Terminal, New York City.

THE WESTINGHOUSE ELECTRIC & MFG. CO. announces the reorganization of the supply sales department and the establishment of a merchandising sales department, which are the major changes in the organization, according to announcement made recently by H. D. Shute, vice-president of the company. The changes, which entail the promotion and transfer of a number of officers,

were effective May 1, at which time the new merchandising sales department began to function. J. J. Gibson, manager of the supply sales department, becomes assistant to vice-president in the new plant of organization. In his new position Mr. Gibson will have general supervision over the activities of both the supply sales department and the new merchandising sales department. A. A. Brown is appointed manager of syndicate operation; J. S. Tritle, manager of the St. Louis office of this company, becomes manager of the merchandising sales department; T. J. Pace, assistant manager of the supply department, becomes manager of the supply sales department; C. E. Allen, manager of the central station division of the Chicago office, becomes manager of the St. Louis office, succeeding Mr. Tritle; George Baily, assistant to the manager of the supply department, becomes supervisor of distributing agents; A. C. Morrow, assistant sales manager of the Westinghouse Electric Products Co., becomes assistant to the manager of the merchandising sales department, and J. J. Dorney, manager of the industrial division, St. Louis office, becomes assistant to the manager of the merchandising department.

THE REPUBLIC CARBON CO., INC., announces that its offices, including the sales office, have been moved to Milwaukee, Wis. The plant remains at Niagara Falls, N. Y., the only change being that of concentrating the executive forces in one office.

THE ALBERGER CHEMICAL MACHINERY CO., INC., has moved its general offices from Grand Central Palace to 103 Park Ave., New York City.

THE DARCO CORP. of Wilmington, Del., announces that all sales of Darco and other refining materials manufactured by this company will be handled through the Darco Sales Corp., 45 East 42nd St., New York City.

THE GENERAL CHEMICAL CO. has moved its New York office from 25 Broad St. to 40 Rector St.

Manufacturers' Catalogs

THE CALLOW ROCK LIME CO., LTD., 810 Salisbury House, London, England, has issued a pamphlet on "Chemical Lime." Pages 1 to 16 deal generally with the use of lime in the chemical industry, while the last 16 pages deal with the production and the chemical and physical properties of Callow Rock lime products. Copies will be sent on request.

THE DAYTON-DOWD CO., Quincy, Ill., calls attention to its latest bulletin covering Type CSU multi-stage automatically balanced centrifugal pumps. The booklet is well illustrated.

THE WESTERN WHEELED SCRAPER CO., Aurora, Ill., announces the publication of Catalog 50, on "Dump Cars and Machinery for Handling Earth and Stone." This attractive 160-page catalog is in three sections. The first section illustrates and describes dump cars, railroad trestle filling, railroad ditching, industrial haulage, levee and dam construction and coal storage; in the second section (the contractors' equipment section) elevating graders, dump wagons, scrapers and plows are illustrated and described, while the third section deals with road graders, planer attachments, track crushers, batch-boxes and industrial railways.

INGERSOLL-RAND CO., New York, in Bull. 10,004, describes Price type "PO" horizontal, single cylinder, single acting, direct-injection oil engine. Probably the most outstanding feature of the design of these engines is the shape of the combustion chamber and the arrangement and construction of the spray nozzles used for direct injection of fuel. With this system fuel injection and complete amonization are obtained without the use of high-pressure air, the ignition being at all times by the heat of compression only. Other noteworthy features are inclosed and oil-tight crank case; the pressure lubrication system for oiling all important bearings including cam rollers; the continuous filtration of lubricating oil; and the completely water-jacketed cylinder barrel and heads."

THE AMERICAN ATMOS CORP., New York City, has issued an interesting bulletin on the Paul breathing apparatus, which is illustrated and described.

THE HARDINGE CO., New York, has issued a new condensed bulletin on the Hardinge conical mill. This bulletin covers in a very concise manner the principle of operation of the mill, its adaptability to industrial and metallurgical grinding problems, and gives general dimensions covering the different types of mills, as well as tables showing sizes, powers, and capacities for different conditions of grinding.

Industrial Developments

CERAMIC—The Standard Sanitary Mfg. Co., Pittsburgh, Pa., has increased production by about 25 per cent at its Tiffin, O., plant during the past fortnight, giving employment to additional workers. Fires have been started in four additional kilns. A night schedule has been placed in operation in certain departments in addition to the regular day working basis.

The Hazleton Brick Co., Hazleton, Pa., is arranging for the immediate resumption of operations at its plant, following a shut-down for a number of months past.

The George J. Markley Co., Mineral City, O., has inaugurated a capacity schedule at its two local clay products plant. Employees have been granted an increase in wages of 5 cents an hour.

The Thomas Maddock's Sons Co., Trenton, N. J., manufacturer of sanitary ware, is running on a full time, full capacity basis, with regular working force. The company is said to have orders on hand to insure this rate of output for a number of months to come.

Manufacturers of clay sewer pipe at Urichsville, O., have advanced the working schedule at their plants from a 9- to 10-hour day basis.

LEATHER — The Dunn-Green Tannery, Hudson, Mass., is arranging for the early resumption of operations at its plant for the production of chrome side leathers.

The Murray Leather Co., Woburn, Mass., has adopted a capacity basis of operation, on a schedule of 1,500 sides of high-grade leather daily.

The American Hide & Leather Co. has resumed operations at its plant at Lowell, Mass., following a shut-down for a number of weeks past.

RUBBER — The Republic Rubber Corp., Youngstown, O., has increased operations at its plant since the first of the month to double the operating capacity of previous weeks. A three-shift schedule has been adopted in the inner tube manufacturing department, succeeding a two-shift operating basis, while a double shift basis has been inaugurated in the truck tire department instead of single shift, as heretofore.

The Keystone Tire & Rubber Co., New York, N. Y., is operating at maximum capacity at its plant, and plans to soon run on an overtime schedule, on a basis of three 8-hour shifts.

The Studebaker-Wulff Rubber Co., Marion, O., is arranging for an immediate advance in production at its plant; the working force will be increased. During the past fortnight the company has booked orders for 15,000 casings and 18,000 inner tubes.

Tire plants at Akron, O., are running on a normal basis, with total production approximating 80,000 tires a day. A call has been issued for 1,000 additional skilled workers at once, divided among the different mills. It is expected that the "peak" production period of 1920 of 100,000 tires daily in this district will be reached early in July.

OIL—The Standard Oil Co. has resumed operations at the lubricating oil unit of its refinery at Wood River, Ill., which has been closed down since last July.

The Sinclair Oil Corp., New York, N. Y., is increasing operations at its different oil-field properties and oil refineries.

IRON AND STEEL—The Minnesota Steel Co. has placed its blast-furnaces and open-hearth plant at Duluth, Minn., in operation. Production will soon begin at the new sheet mills, now nearing completion.

The Midvale Steel & Ordnance Co., Philadelphia, Pa., is arranging plans to blow in its blast furnace at Coatesville, Pa., on May 22, which has been idle for some time.

The Hydraulic Steel Co. has resumed operations at its sheet mill at Canton, O., following a protracted idleness.

The Shelby Iron Co., Birmingham, Ala., is arranging for the early resumption of operations at its furnace, now undergoing repairs.

The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., is running on a full 100 per cent basis, and will maintain this schedule for an indefinite period.

The McKinney Steel Co., Cleveland, O., has resumed operations at six open-hearth furnaces, developing close to normal production.

The Wickwire-Spencer Steel Corp., Buffalo, N. Y., is arranging for early increase in operations at its plant, now running at about 70 per cent of normal.

METALS—The American Smelting & Refining Co. has resumed operations at its smelter at Hayden, Ariz. The copper department of the company's smelting plant at El Paso, Tex., has also been placed in service. Four out of five of the company's smelters in Mexico are now in operation.

MISCELLANEOUS — The Semet-Solvay Co. has placed 60 additional coke ovens in operation at its plant at Birmingham, Ala. The bulk of distribution is to the furnaces of the Republic Iron & Steel Co.

The Enamel Products Co., Elyria, O., has adopted a capacity schedule at its plant, with orders on hand to insure production for a number of months on this basis.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold a joint meeting with the Pacific Division of the Association, on the occasion of the annual meeting of the latter, in Salt Lake City, June 22 to 24.

AMERICAN ASSOCIATION OF ENGINEERS will hold its eighth annual convention at Salt Lake City, Utah, June 4-6.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Pittsburgh, Pa., Sept. 5 to 9.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 21, 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, Canada, June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its nineteenth annual meet-at Bigwin Inn, Bigwin Island, in the Lake of Bays district, Ontario, Canada, on June 21, 22 and 23.

AMERICAN OIL CHEMISTS' SOCIETY will hold its annual meeting at the Grunewald Hotel, New Orleans, La., June 5 and 6.

AMERICAN PULP AND PAPER MILL SUPERINTENDENTS ASSOCIATION will meet in Kalamazoo, Mich., June 1, 2 and 3.

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting at the Bureau of Mines auditorium, Pittsburgh, Pa., on May 25 and 26. The International Steel Exposition and Convention of the society will be held in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

ANNUAL SAFETY CONGRESS OF THE NATIONAL SAFETY COUNCIL will be held in Detroit, Mich., Aug. 28-Sept. 2.

CERAMIC SOCIETY (London) is to have a foreign trip to Sweden and Denmark from May 27 to June 10.

CHAMBER OF COMMERCE OF THE UNITED STATES is holding its tenth annual meeting in Washington, D. C., May 15 to 18.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

NATIONAL ASSOCIATION OF PURCHASING AGENTS EXPOSITION (the "Informashow") will be held in connection with the seventh annual convention of the association at Exposition Park, Rochester, N. Y., May 15-22.

NATIONAL COAL ASSOCIATION will hold its annual meeting at Congress Hall, Chicago, May 24-25.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NATIONAL FERTILIZER ASSOCIATION will hold its twenty-ninth annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 12.

NEW JERSEY CHEMICAL SOCIETY will meet at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

Making A Tariff

DEBATE in the Senate on the Fordney tariff drags its weary length through hours and days and weeks of futile argument. We have forgotten how many thousand items and how many more thousand amendments there are to consider, but we know that only a few hundred have thus far passed the critical attention of Senators who are opposed to the measure. But we find no difficulty in understanding the interminable delay resulting from such a gem as we quote from the *Congressional Record* of May 2.

> Mr. SMOOT—Acetic anhydride is not made from calcium carbide.
> Mr. KING—I did not say it was.
> Mr. SMOOT—It cannot be made in that way.
> Mr. KING—I did not say it was made that way.

The best that can be said for the debate was that it was conclusive and probably satisfactory to both sides. If we engaged in prize contests, we should be inclined to offer a substantial prize for the best essay of not to exceed 500 words on the relation of this verbal tilt to the welfare of American chemical industry.

The Chemical Engineer Of the Future

A SIGNIFICANT event has taken place marking a milestone of progress in chemical engineering education. Our news pages this week carry a detailed account of the meeting held last week in Brooklyn under the auspices of the American Institute of Chemical Engineers, at which representatives of twenty-two universities together with a number of leading chemical engineers in industry discussed the report of the Institute committee on chemical engineering education. Letters from a score of other institutions at distances which prevented their being represented indicate the wide interest which this conference aroused.

The fortunate auditor would find it difficult to focus in small compass the fine spirit of that meeting. The admirable report of the committee of the Institute presented by its chairman, Dr. ARTHUR D. LITTLE of Boston, formed the basis for discussion and kept the attention of the conference from wandering far afield. It was impressive to find that so many had been thinking progressively along educational lines. It was more impressive to find that both the producer and the consumer of the product—the university man on the one hand who trains the chemical engineer and the employer on the other who utilizes his services—should be so completely in accord as to desirable traits and qualifications. Finally, it was most impressive to realize that the university men were so unanimous in their agreement as to the broad principles of chemical engineering training.

A keen appreciation of what is meant by a chemical engineer made it much easier to arrive at substantial agreement. "A man not primarily interested in processes of manufacture, how to make sulphuric acid or sugar or paint, but primarily interested in the quantitative study of unit operations of chemical processes such as filtration, grinding, distillation, drying, etc." A thorough grounding in broad principles of science was urged and a tendency away from specialization, particularly in a four-year course. The recommendations adopted by the conference should be studied by everyone. A committee will be appointed to carry on the splendid work and take up the details. Much power to that committee! On its shoulders rests a great task, a unique privilege, a galvanizing obligation. The work brilliantly conceived and begun with a thoroughness which kindles enthusiasm must be pursued vigorously and with a real sense of consecration.

Why Not Reduce The Percentage Overhead?

ANY business that paid out 80 per cent of its total expenditure for overhead would be subject to criticism for poor management. But this is just the situation in which it looks as though Congress would like to place the Chemical Warfare Service. Ultra-economy, if followed to the limit proposed by the House of Representatives, will certainly not be real economy. It will be the worst of penny-wise policy. A service devoting 80 per cent to overhead—i.e., made 20 per cent financially effective—would not be pleasing to anyone. Least of all would it satisfy those who thoroughly appreciate the importance of defensive chemical warfare.

During the present fiscal year the C.W.S. organization is spending about $2,500,000; for the next year the House bill provides for it $500,000. Of this small sum 80 per cent will be needed simply for overhead, principally the maintenance and operation of the essential parts of Edgewood Arsenal, without permitting any productive effort in research, development or proving. General FRIES has estimated that at least $1,100,000 would be needed for the proper maintenance and operation of Edgewood and to provide for the essential items in chemical and mechanical research and proving. The proposition now is before the Senate for further action.

For some time the General Staff of the Army was seriously considering whether C.W.S. should be discontinued and its functions transferred to the Ordnance Department of the army. But a careful, and one might even say unfriendly, study of the situation made it clear that continuance of the chemical organization on an independent footing was absolutely essential, not only from a scientific but also from a military point of view. The navy too has studied the situation and is placing the responsibility for much of its chemical warfare research upon the C.W.S. organization. It is

evident, therefore, that this unit is regarded by both army and navy as an important and integral part of the military organization of the future. It is therefore only reasonable to ask that the Senate shall grant Chemical Warfare Service as large a percentage of the army appropriation for next year as was given during the current period. We urge upon the Senate the merit of amending the bill to appropriate not less than the minimum of $1,100,000 which General FRIES has so convincingly shown to be essential. With that sum the overhead would be only 35 per cent of the total, which is a vast improvement over 80 per cent.

Compromise in Flotation Litigation

NOT since the days of litigation between representatives of the vacuum filtration industry has the metallurgical world been treated to so long, spectacular and expensive a legal contest as has been waged between Minerals Separation, Ltd., and various American copper-mining companies. Beginning with the first suit against JAMES M. HYDE and the Butte & Superior Copper Co., and ending with the compromise between the same plaintiff and the Miami Copper Co., flotation litigation has held a prominent place in the highest courts of the land. In fact we had become so accustomed to a continuous performance that the compromise in the Miami case came as somewhat of a surprise to those who have followed the varying fortunes of the contestants.

With the compromise much that was vital in the controversy now becomes of purely academic interest. Abstruse scientific problems were involved, and it was hoped that, if litigation were necessary, one of the beneficial results would be shedding of light on these unsettled questions. Consequently to the scientific and technical mind there is in the termination of this litigation a consciousness of failure to achieve a very desirable end. Nevertheless we must justify the compromise on the ground of business expediency and leave to more competent means the determination of the scientific principles involved in the process. We shall learn more from non-partisan scientific investigators than from experts retained by contending factions.

The Institution of Chemical Engineers— A Message of Welcome and Congratulation

LAST fall at a dinner of the American Institute of Chemical Engineers, Sir WILLIAM POPE told us of the great desire on the part of many men prominent in chemical industries for a British society similar to the American Institute. There was something distinctly prophetic in the expressed wish, for now comes word to us that the Institution of Chemical Engineers was inaugurated on May 2 in London by a distinguished gathering of men prominent in the chemical industry of Great Britain.

The chemical industry of Great Britain has developed without the chemical engineer. As Sir ARTHUR DUCKHAM said in his address as chairman of the meeting, "We have a number of engineers with a smattering of chemistry and a number of chemists with a smattering of engineering, but what we want is men thoroughly trained in both subjects." The program of the new Institution has, as one of its principal aims, the development of a satisfactory curriculum for the training of chemical engineers. The problem is different from the one which confronts American educators in this field, for we have courses of training and a product to study. In England the courses and the product must be created. The creation of such an Institution in Great Britain required courage. Considerable conservative opposition was encountered, comparable to that which exists in some few lines of manufacture in this country. But American chemical engineers will welcome the inauguration of the Institution. The recognition of the profession in Great Britain will inevitably have a desirable effect on its prestige in America. We can hope that the future will bring to the new Institution a career as distinguished and as progressive as that of the American Institute of Chemical Engineers. The experience of the older organization should be of inestimable value to the one newly created, and we should extend to the English Institution a close, organized and fraternal liaison. Our compliments and congratulations are extended to the organizers.

Opportunities In Biochemistry

IN THE May issue of our very lively little contemporary *The Chemical Bulletin*, published by the Chicago and other Midwest Sections of the American Chemical Society, there is an illuminating article by CHI CHE WANG on "Hospital Chemistry." It confirms the position which we have maintained of the growing need of chemists in the practice of medicine. The author speaks with knowledge and authority of modern hospital requirements in clinical chemistry. Formerly a few qualitative tests of urine for albumen, sugar and "acetone bodies" were substantially all that was demanded, and could be made by almost any laboratory assistant. But blood tests and tests of the cerebrospinal fluid are becoming of leading importance. Indeed, he well says that any metabolic disorder is manifested in the blood before any noticeable change is brought about in the character of excretions. By the introduction of microchemical methods it has become possible to make quantitative determinations of a number of blood and urine constituents with a fraction of a cubic centimeter of material in less than an hour's time. With a total of less than 25 c.c. of blood, determinations may thus be made of fat, lecithin, chloresterol, chlorine, sodium, calcium, potassium, magnesium, phosphorus, sugar, creatine, creatinine, uric acid, urea-nitrogen, non-protein nitrogen, oxygen and alkali reserve. Emphasis is laid on the value of the study of nitrogenous compounds in the blood, and of blood gases in diagnosis. Also important is the study of determination of the mineral content as well as the alkali reserve of the blood plasma, and the measurement of the CO_2 tension of the alveolar air.

This work may not be entrusted with safety to the type of young person "majoring in chemistry" elsewhere referred to in the same journal, who determined the atomic weight of copper by dividing the weight of the crucible by that of copper. Or who held that a Pyrene fire extinguisher is filled with "carbon bicuspid." Or who did not make analyses in duplicate because he "didn't know which one to take." Work must be done with great accuracy because often the quantity of material available is very small, and it must also be done rapidly because also very often the patient is not in a condition to wait—and does not wait.

What is needed of hospital chemists therefore is ac-

curacy, economy with materials, alertness and swiftness, besides a good working understanding of biological and pathological chemistry. It may be asking too much of the physician to make him sufficiently proficient in the chemistry of metabolism and of growth so as to do his own testing. At all events, whether we ask it or not, very few practitioners of medicine are able to do this. The course of study in medicine is already so long that there is a serious question as to the wisdom of making it longer. That might cause a shortage in the profession. But every town of fair size needs a biochemical laboratory in charge of a competent chemist, familiar with the biological, physiological and pathological aspects of his profession.

Such a laboratory should soon pay for itself, in charge of a person with a proper sense of medical needs, practice and methods, and with enough of a head for business to manage his own affairs. If a chemist has the professional equipment but is, as many are, incapable of business, and who must work for somebody else on a salary, we've no doubt that successful apothecaries would be glad to set up such a laboratory and maintain it. The information indicates a widespread need of chemists that should be interesting to many who are now looking for work.

Bogus Degrees

WE CONFESS we have been severe in our criticism of foreign journals that advertise degrees for sale from American universities. And yet we think we were right. Any so-called American university that offers to sell degrees is not an honorable institution, and every one should know it. Academic life in the United States is distinctive, as is that of every country, but it is honorable. The sale of degrees is dishonorable, and is so regarded here as well as elsewhere. Indeed, the act of advertising degrees for sale is construed to be a fraudulent use of the United States mails, and those who engage in it are prosecuted. Thus one HELMUTH P. HOLLER, head of the "Oriental University" in Washington, D. C., was lately arrested on such a charge; he has been indicted, and his case will shortly come up for trial.

But there is no use in denying that in some states and in the District of Columbia a nasty situation exists. In New York State no institution may grant degrees unless it has at least $500,000 worth of property and conducts its affairs under the sanction and approval of the Board of Regents. The high character of the Regents of the State of New York makes this provision an assurance of scholarship and of proper administration. In a report made in 1912 by the Carnegie Foundation for the Advancement of Teaching it is said that the states of Pennsylvania and New Jersey had also made provision to prevent fraudulent and unworthy institutions from organizing or from prosecuting their unsavory business. There is no report on this subject available since 1912, and it is probable that other states have set their houses in order since then. But not all by any means, and the District of Columbia seems to lead in this kind of disorder, despite the excellent George Washington and Catholic Universities which are located there. Unless it has been changed since, and we doubt it, the sole requirement in the District of Columbia is that five citizens—and it makes no difference who they are or how ignorant they may be—shall sign a document stating that it is their intention to incorporate under whatever name they choose to take. The Recorder of Deeds on presentation of such a document is obliged to give them a certificate of incorporation—and there they are. Of such blights of mildew were the "Potomac University," that when it was examined had assets to the value of $450, with the president as a member of every faculty and the other members mostly imaginary. The Oriental University of Washington we have already mentioned; it is an old offender. The Odessa University used to sell degrees for $10. This, like the others, was "incorporated under an act of Congress" (which compelled the Recorder of Deeds to give anybody a certificate).

The trouble is that the latest available records are 10 years old. We wish that some competent body would make a careful investigation of the fake colleges and universities—so as to show them up for what they are and put them out of business if possible. Some state legislatures are too ignorant to know or to understand the vice of granting degrees to those who have not earned them. The action of the Kentucky State Legislature in almost prohibiting the teaching of evolution is an example of the cultural quality of some lawmaking bodies.

Fortunately the penalties for fraudulent use of the mails keep these degree factories rather quiescent in this country, and men of scholarship know the contumely which the purchase of a degree from the "Oriental University," for instance, would bring upon them. The butcher and baker and candlestick maker do not aspire to degrees, and as for chiropodists, they are all "Docs" by tradition as soon as they buy their knives and scissors—except in some states, where they must pass an examination to practice. Then they are licensed chiropodists in fact and "Docs" in a fiction of usage.

Another Russian Chemist Saved

LAST winter we voiced a wonder which had doubtless risen in many minds, a wonder as to the whereabouts and circumstances of many Russian chemists of note. Ample information has since accumulated that whatever their whereabouts, those who are left are certainly living in most pitiful circumstances, even verging on death by exposure and starvation. In those instances where they are not actually prevented, it appears that they are continuing their researches with a fine and unquenchable determination, handicapped by the lack of apparatus, chemicals and books, things which ordinarily would be regarded as essential.

At that time the figurative suggestion was made to "send out a search party to find OSTROMISTLENSKY; his contributions to the chemistry of rubber have been of high rank, and his splendid talent and understanding would be a godsend to the industry." Some weeks later contradictory reports were received—one that he was alive, another that he was killed at Moscow. We are now able to give the good news that Prof. OSTROMISTLENSKY has recently reached America and, we are informed, now is engaged in research work in the laboratories of the United States Rubber Co.

We welcome this savant! Doubtless he will give us much more than we give him. Which circumstance only urges us to even the account by sending generous aid to the pitiable workers he has left behind.

Readers' Views and Comments

Bad Paint and Good Medicine

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with interest the editorial in your issue of April 12, 1922, under the caption "Bad Paint and Good Medicine," in which you call attention to the able work of Dr. John M. Müller and his colleagues of the University of Pennsylvania on the element germanium. The action on the organism of Dr. Müller's aqueous germanium extracts brings to mind the properties of the waters of Ponce de Leon's fabled fountain of youth, and also recalls the fact that germanium does actually occur in waters of medicinal repute. Thus Bardet (*Compt. rend.*, vol. 158, 1914, p. 1278) found the element in the mineral waters of Vichy, where it may have exerted some therapeutic action, although present in homeopathic amounts.

I hope, however, that I will be pardoned for disagreeing with those parts of your editorial which locate all the sources of this new fountain of youth at the confluence of the Schuylkill and the Delaware. I am sorry to spoil your clever little story, with its local color and its stirring note of loyalty to alma mater, but the fact remains that your correspondent is the chemist to whom you have so kindly referred in your editorial, and that his alma mater is situated on the Charles and not on the Delaware. It must also be pointed out that this rediscovery of the element took place 6 years ago and that a half dozen universities have been working on the germaniferous material since that time.

The writer's original papers announcing the occurrence in workable quantities of germanium in certain zinc materials were published in 1916 and 1917 (Buchanan, *J. Ind. Eng. Chem.*, vol. 8, p. 585, and vol. 9, p. 661). Although the zinc materials there described made available the first real supply of germanium since the days of Winkler, there was nothing new in the announcement that germanium is frequently found associated with zinc. Urbain (*Compt. rend.*, vol. 149, 1910, p. 602) by spectroscopic methods had identified germanium in thirty-eight out of sixty-four blendes examined, while Hillebrand and Scherrer (*J. Ind. Eng. Chem.*, vol. 8, 1916, p. 225) had announced its detection, also by the spectroscope, in several blendes, notably in a Missouri sulphide.

The classical work of Winkler was performed on very low-grade material containing, according to Urbain (*Compt. rend.*, vol. 150, 1910, p. 1758) not more than 0.03 per cent germanium. It was therefore not surprising that the writer's announcement of a commercial material containing approximately 0.25 per cent GeO_2 should arouse the interest of many laboratories working on the rare elements. Among the first to obtain samples were Prof. Browning of Yale and Prof. James of New Hampshire College. At least two papers have been issued from Prof. Browning's laboratory (Browning and Scott, *Am. J. Sci.*, vol. 44, 1917, p. 313; Browning and Scott, *J. Phys. Sci.*, vol. 46, 1918, p. 663). Prof. James has published some of his work under the title "The Extraction of Gallium and Germanium From Zinc Oxide" (James and Fogg, *J. Am. Chem. Soc.*, vol. 41, 1919, p. 947). Material was also sent to Cornell University, to the University of Pennsylvania and to several others; from the two first named we have had the more recent work of Dennis and Papish (*Chemical News*, vol. 123, 1921, pp. 190 and 202) and that of Dr. Müller (*J. Am. Chem. Soc.*, vol. 43, 1921, pp. 1085 and 2549).

Although, as has been pointed out, a number of university laboratories throughout the country have been contributing to this new germanium literature, we are indebted to Dr. Müller and his co-workers for the first suggestion of an application of the element to human needs. We do not forget that since the days of the iatrochemists a new chemical species has always been hailed as a panacea; nevertheless we must believe that an element related to arsenic on the one hand and to carbon on the other has at least an even chance to prove itself of medicinal value. Germanium chloroform, for example, has been known since the days of Winkler.

New York City. G. H. BUCHANAN.

EDITOR'S NOTE: It is unfortunate that our information about Mr. Buchanan's alma mater was not as accurate as that about Dr. Müller's work on the therapeutic uses of germanium. Evidently the friendly rivalry between Harvard and Pennsy extends beyond the field of sport!

Too Much Specialization in Engineering Education

To the Editor of Chemical & Metallurgical Engineering

SIR:—In a recent review of Prout's "Life of George Westinghouse" your distinguished consulting editor, Mr. Hendrick, expressed his regret that the chemical engineering industry had produced so few broad-minded leaders of the type of Westinghouse in the electrical engineering industry. Mr. Hendrick hinted, moreover, that this failure to produce chemical engineers of broad vision and imagination was due to causes not difficult to trace. I would suggest that one important cause can be traced in your illuminating tabulation, last June, of the curricula of chemical engineering courses taught in American colleges. A great many of those curricula obviously are not designed to produce graduates of broad vision and imagination. Some of them seem designed to exalt the department of chemistry at the expense of professors teaching cultural or broadening courses. Under such specialized curricula, a normal student of moderately wide interests entering college when he is 18 is changed in four impressionable years into a chemical-minded graduate so unsympathetic with everything except his specialized field that it is no wonder Mr. Hendrick lamented the lack of great chemical engineers to compare with Westinghouse and his type in electrical engineering.

There are some colleges in the country that have harkened to the many recent criticisms of engineering education—such as the famous Mann report—and are broadening their engineering curricula. These progressive institutions are swayed also by the important fact that less than half of the graduates of engineering colleges remain strictly in technical work. But on the

other hand, other colleges are narrowing their chemical engineering curricula, possibly because they observed from your tabulation that there were several curricula even narrower than their own, and this offered an excuse for a revision in favor of greater specialization. I believe that our extreme specialization in engineering education is a consequence of the American tendency to go to excess. European engineers are frequently amazed at the ignorance of American engineers in any field except their specialty; and, for that matter, many American employers suffer the same amazement.

I am not in favor of the 6-year engineering curriculum; I agree with your correspondent Edward Hart of Lafayette College that many students could not afford so long a college career. Moreover, four years of college atmosphere and all that it implies is sufficient at that stage of the ordinary young man's career. The comparison with the law school and medical school courses is not an apt one, because lawyers and physicians are not compelled to mix into business and industry to such an extent as is the engineer. Law and medicine remain distinct professions, with codes and points of view separate from the world around them.

While I am in favor of what T. A. Rickard and Prof. Burr call professional status for the engineer, I do not think that most engineers can sit back in offices and wait for work to come to them, but must enter industry and conform to (or improve) the conditions existing there. In such a capacity too narrow or professional-minded a point of view handicaps the engineer. As J. E. Spurr, editor of *Engineering and Mining Journal-Press*, said in a commencement address in Michigan: "The handicap of the college-bred man is a lack of initiative and a too great fear of doing this or that which is below his dignity." It seems to me that, instead of producing specialized technicians of rather narrow, unimaginative views, the engineering colleges should produce adaptable, broadly educated men well grounded in the fundamentals and larger applications of science. This can be done in four years if the curriculum is not too highly specialized.

By the way, I should like to express my appreciation of your improved editorials. No one could accuse your editorial staff of narrow, unimaginative views. Since the demise of the *Mining and Scientific Press*, your editorials are the best written and most inspiring of the engineering periodicals, in my opinion.

New York University. P. B. McDONALD.

Properties of So-Called Amorphous Metal

To the Editor of Chemical & Metallurgical Engineering

SIR:—Considerable attention has recently been given to crystalline slip in metals, particularly by Jeffries and Archer.[1] These contributions have shown clearly that ductility and related properties are characteristic of the crystalline state, but the occurrence of a high degree of malleability and ductility as peculiar to the metallic state has not been emphasized. Tammann[2] has pointed out that ductility is not a function of any particular space lattice, but depends on the lattice being built of the same kind of atoms between which no valencies are active. According to J. Stark[3] metallic crystals may be considered as made up of rows of positive ions between which are the more or less free negative electrons. Gliding may therefore take place along any plane separating two rows of ions without disrupting the structure, since all positions in the space lattice are equal. However, at the surface any appreciable slip requires the separation of the atoms.

If the force exerted along the gliding plane is sufficient to separate the surface atoms, why does the slip halt and not become a simple cleavage? This question, which is fundamental in the theory of metallic flow, has been asked and answered by Knight.[4] His answer follows the generally accepted amorphous theory. In the present note it is desired to point out that the conception of the amorphous layer as a supercooled liquid leads to some conflicts with experimental data and that on the other hand it is possible to explain the phenomena connected with crystalline slip on a somewhat different basis.

The properties of a metal after inelastic deformation have the following relations to those of the undeformed metal:

(1) Greater resistance to further deformation.
(2) Higher electrical resistance.
(3) Negative thermoelectric force to the undeformed.[5]
(4) Higher specific heat.[6]
(5) Lower density except in the case of bismuth.[7]
(6) Scratch hardness is the same.[7]
(7) Electrolytic potential anodic.[8]

The resistance to further deformation is logically explained by Jeffries and Archer as due to the absence of planes of slip in the amorphous material and a decreased density is logical for a supercooled liquid, but the reasons for the electrical properties present greater difficulties. The thermoforce has been found to be the same in both the liquid and the solid state for all metals except bismuth,[9] so that an assumption of a different thermoforce for the supercooled liquid than for the solid at the same temperature is unjustified. The greater electrical resistance of liquid metals is accounted for by the greater amplitude of vibration of the ions,[10] so that an assumption of higher resistance for supercooled liquid metal involves a greater freedom of motion of the atoms of a supercooled liquid than the solid has at the same temperature, which is not in accord with the higher specific heat of flowed metals. The specific heat of liquid metals is lower than that of solid metals.[11] Altogether, the amorphous layer—if one is present—does not have the properties of a supercooled liquid.

A further development of Stark's views of crystal gliding will explain the change of properties on inelastic deformation satisfactorily. If we consider the separation of the metal ions to a greater distance than they can be elastically displaced from their position in the space lattice, they will tend to take on the free electrons which are characteristic of the metallic structure. Such a process will result in electrons being held in common between two metal ions, a sort of forced molecule formation. As more of these pseudo molecules are formed, the resistance to deformation will increase, and since the number of free electrons is

lowered, the electrical resistance will increase and the thermoforce be more negative. The increase of specific heat would follow from the greater rigidity with which the atoms are bound.

If an "amorphous" layer exists, and it undoubtedly does in some cases, its properties are better explained on this basis than on the basis of it being a supercooled liquid. I regard the amorphous material as a disperse phase in which the particles are held together by half-bound electrons. Such a theory explains the properties of disperse systems in general without such mechanical assumptions as the key action brought forward by Jeffries and Archer. The question arises as to why it is not possible to have crystals entirely built up of disperse forms. The orthorhombic form of iron disulphide, marcasite, appears to bear such a relation to the isometric modification, pyrite.

The restoration of the original properties of the flowed metal by annealing follows from an increased freedom of the ions and electrons so that they may return to their normal position in the space lattice.

Chicago, Ill. REGINALD S. DEAN.

Ido, the New Universal Language

To the Editor of Chemical & Metallurgical Engineering

SIR:—There has been some talk lately about a world language, and the League of Nations is considering the adoption of such a language. The International Research Council is busy investigating the subject. Scientific men are quick to realize the advantages of such a medium of thought exchange.

Such a language, though, for scientific purposes must embody the following features: It must be easy to learn, either passively, for reading, or actively, for writing and speaking; it must be precise, so that the chances of ambiguity are reduced to a minimum and clearness will be an outstanding feature; and it must be one which will contain the least number of words new to the scientist—that is, as many as possible of its words must be easily and quickly associable with one's native language.

Such a language exists. It is Ido, the offspring of Esperanto—the refined and improved Esperanto. It is easily and quickly learned, and the scientific man can learn the Ido of science, his own field, in a marvelously short time. This is due to the short, compact grammar, which is typically American, in that it is a distinct time saver. It is very precise, much more precise than the natural languages, for in Ido one word represents one idea, and by means of a comparatively small number of affixes, that one idea can be presented in any of its forms, and without danger of being misunderstood. And Ido, being a language whose words are selected in accordance with the principle of the greatest internationality, presents less new words to be learned. Also the words are a trifle shorter than in any other language.

In fact, the language is far superior to any that has preceded it, and while it may have (it undoubtedly does have) some faults, still it is superior to its parent, Esperanto. Dr. Zamenhof deserves much credit for his work, but working alone, he made mistakes that he could not see, because he could see his work only from one angle, but when the Delegation for the Adoption of an International Language (which was appointed at the time of the World's Fair in Paris in 1901) met in 1907, the scientists which composed that committee decided against Esperanto as it then stood, but decided to adopt it in principle, in accordance with the project Ido, which was done, and so was Ido born.

Science has at its hand a tool for international comprehension better than any national language, a language devoid of idiotisms and illogical expressions, which will enable all to have a fair chance. Will science use that tool? I believe that it will. The present trend of events shows it.

A few opinions by recognized scientists will not be out of place before I close.

Prof. W. Ostwald, emeritus professor of Leipzig University, philologist and Nobel prize-winner for chemistry, says (International Language and Science): "As is well known, we scientific men suffer a good deal from the fact that the same words are frequently employed for vague ideas of daily life as well as for the perfectly definite concepts of science. This is indeed one of the most important reasons why new designations for scientific concepts should, so far as possible, be taken from the dead languages, such designations being thereby already international. It ought therefore to be a comparatively easy task to devise by means of this international material and the linguistic rules of the language of the Delegation a system of international names for the clearly defined concepts of the different sciences." Prof. Ostwald was the chief worker on the chemical terms of the language of the Delegation (Ido).

Prof. Otto Jespersen, philologist, University of Copenhagen, says (International Language and Science): "The result [of the work of the Delegation] is a language that everyone can easily master and which possesses the advantage over other languages that it is based on rational scientific principles, and therefore need not fear that some fine day it will be replaced by another and sensibly different language. Naturally improvements will be effected in details where the fundamental principles have not been sufficiently worked out, but the foundation is sound."

Prof. A. Meillet, of the College of France, says (in Les Langues dans L'Europe Nouvelle): "It is, on the other hand, easy to proceed more logically and consequently in a manner more satisfying and clear, concerning the word-formation, than Esperanto did. This is shown by the creators of Ido, a language founded on the same principle as Esperanto, but in which those principles were applied with greater rigor."

Ido is the crown of the international languages, and it is almost certain that the League of Nations will adopt it as the official language of the League. It is a popular language in Europe, and I am informed that Esperanto is there meeting with the fate of Volapuk—obscurity. EARL WALTER SUTTON.

Elyria, Ohio.

The Throwing Power and Current Efficiency of Zinc-Plating Solutions

In the report of the Baltimore meeting of the American Electrochemical Society in the issue of CHEM. & MET. for May 10 it was stated on page 878 that a paper on this subject was presented by Prof. W. G. Wood and T. Fuwa. The name of the first author should have been given as Prof. W. G. Horsch, who is research associate in the research laboratory of applied chemistry at the Massachusetts Institute of Technology, where the investigation which was the subject of the paper was carried on.

The Business Side of Chemical Manufacturing

This Is the Third Article of This Series and Continues the Study of Marketing With the Sales Department —The Functions of the Sales Manager and the Salesman—Their Methods of Work—Critical Suggestions in the Chemical Field

By CHARLES WADSWORTH, 3d

GROUPED under the inclusive title Sales Department are all of the remaining departments which contribute to the marketing process. Rather unsystematically we shall study the actual sales work first. The other departments are more easily considered in their relation to the sales department itself. The sub-departments fall conveniently into two groups. They may be called for want of better names the clerical and the technical groups. In the first group are the credit, traffic and collection departments. The procedure in these departments is almost routine. In a great many firms, after the policy has been established by the sales manager, the work is carried out by clerical labor of mediocre caliber. A very brief discussion of procedure will therefore suffice. The technical group, including sales research (sales engineering) and sales service or trouble department, is somewhat embryonic in the industry as a whole. It is becoming increasingly important and its importance is beginning to be realized. The interest for technical men is great because its operation by technically trained men is imperative. First, however, consider the sales department. Our discussion will be divided into two main parts, one devoted to the salesman and the other to the sales office and sales manager.

The Salesman

There is one widely prevalent myth which in many quarters has assumed the dignity of an axiom. It is to the effect that salesmen should know very little about production and method of manufacture. There are many reasons offered. One wise manager said that a technically informed salesman would lose many sales because he would argue with the customer about theory and the customer would become nettled if his theory were shown to be faulty. Frequently I have heard it stated that the inconsistencies between sales talk and manufacturing practice would make less convincing the salesman who knew manufacturing practice. This last comes sometimes from firms with splendid products and with reputations above reproach. I believe that the myth has its origin in interdepartmental jealousy. The salesman knew he could not enter the technical field and he therefore subconsciously evolved a case against the technical man in sales work. Fortunately the myth is being dispelled by the very much larger number of technically trained men who become salesmen and the increasing number of firms that give their salesmen a special technical training. It is a tenacious myth, however, and will always exist in some places.

A Vision of the Average Salesman

Let us again use the case method of study and develop the faults of the average salesman in the chemical field. We are the purchasing agent, and a card which is brought in to us says: "Mr. Addison Sims [to borrow an immortal name] of the Seattle Chemical & Equipment Co." The calling card is poorly composed. There is too much on it. It makes a poor impression. Mr. Sims enters. He enhances the poor impression, for he is not too well groomed and he is either awkward and ill at ease or aggressive. Those are minor points and would not matter greatly if he were equipped to dispel the initial impression by subsequent activity.

He wants to introduce a pump, or an evaporator, or a chemical. His selling technique is fair. He parrots the advantages of his product and the extent of its use. He has something for you to handle while he talks, a model, or a diagram, or a pound of material. He has voluminous tables of sales data from which he can sometimes calculate a price for a given piece of equipment, though usually, after a protracted search, he "will write you." He almost always tries to make some point of personal contact, golf or what not. But we ask a question just off the memorized field. What has their experience been with the corrosion of the rotor and shell? What factor do they use for the rate of heat transfer? How do they unload a tank car of material? He does not know! He will ask their technical department and let us know. This fact becomes clear that except for the few generalizations about the equipment or product, the salesman is powerless to give technical information.

In the end we know that "there are hundreds of our pumps in use, that the rotor was especially designed by our engineering department and by test has proved most efficient and that now is an advantageous time to buy." We want to know a lot more. We have already asked about corrosion. We want to know also what advantage that type of stuffing box has; a little about packing, perhaps; what pressure the pump will develop; what parts are replaceable; how long it would take to put in a new rotor and shaft; what their experience has been as to the desirability of protecting bearings from overheating and what make of 220-volt a.c. motor they will use on direct-connected pumps—but he can't help us. That is just about the average performance. The average of a number of hundreds. It may therefore be permissible to plead for the technical training of salesmen.

The Selling Campaign

Now for a moment let us cease being purchasing agent and become the shadow of the salesman who has just called on us. What does he do, or rather what should he do outside of the prospect's office? Two things: Organize his selling campaign and keep in intelligent touch with the home office. The first of these two duties is really intelligently performed. The

training of salesmen in using their time to the best advantage has reached a state approaching perfection. Of course, remember that we are talking averages and there are still many firms and many salesmen who squander their effort. But on the whole the prospect list is well picked, well planned and covered with systematic regularity. The degree of supervision exercised by the sales office varies from 100 per cent to zero, but on the whole it is high, which accounts to a large extent for good results in this field.

In general the list of prospects originates in the sales office and often the routing of trips and timing of calls comes from there also. The salesman is thus simply concerned with the mechanics of selling a series of customers. This procedure is entirely logical and closely resembles the division of work in the army between the line officers and the field officers. There are, of course, many salemen who direct their own campaigns, but this is rather the exception.

Contact With the Home Office

The second point, the contact which salesmen keep with the home office, is as close as the office requires, but it is in general not intelligent in the chemical field. There are usually order forms to turn in and order summaries. There are also cards for each call made, which give all the data possible—the date, the company, capitalization, officers, person seen, his position, general attitude, prospect of doing business, etc. This card is usually supplied to the salesman by the sales office, as mentioned above, partly made out, but the data which the salesman adds to the card are the basis of future action. The value of these data cannot be overestimated, and it is here that salesmen are most apt to fall down. Unless the questions are specific, the data will be vague, and yet if the questions are too definite, there is danger that anything outside the questions will be entirely missed. In fact, that is the greatest trouble with the system. A man who is a good salesman is apt to be a poor observer. He is not a receptive type. In addition, if he has no technical training, there will be innumerable stimuli to which he cannot respond and hundreds of hints which he will not understand. There is the cause of death of many companies. Their antennæ missed important messages—messages which became vital. Perhaps it was a simple statement that such and such a company was working on X. Lack of chemical knowledge was responsible for the salesman's failure to realize that X might conceivably be a substitute for his product. The company was therefore not prepared for the competition. Examples are legion of similar occurrences—even if the item had been reported without knowing its significance, the sales office might have discovered the danger.

Selling a Promising Field for Technical Men

Please do not understand me as saying that technically trained men would make good salesmen. That is not necessarily so. But many technically trained men could be trained to make good salesmen and they would make better salesmen of chemicals and chemical equipment than non-technical men would. There are not a few chemically educated salesmen who contributed to the composite picture of the salesmen just presented. They are often inadequately trained in their special field even though they possess technical background.

As a field for technical men selling is distinctly promising. Chemists would do well to consider it not only from the standpoint of a promising future as sales manager but also as a means of surveying the chemical field which few technical positions can offer.

The Sales Office

It is going to be impossible to study the sales manager's office by the case method, for there is too wide a variation. On the one extreme is the sales manager of a sulphuric acid plant, for example, who is also the only salesman. His product is perhaps sold on contract entirely and he makes all of the contracts himself. On the other extreme is the sales manager whose consumer is the wholesaler or retailer and who has to market several hundred products. He has many branch houses and district sales managers. His problems of personnel and distribution are problems which do not touch the other sales manager at all.

There are a number of things, however, with which all sales managers are vitally concerned. All of these focus on the main task of disposing of the company's products at the greatest maximum return over a period of years.

Future Demand

The first function of a sales manager which we shall take up is the estimation of the future demand. Assume that we have a manufacturing unit capable of producing 6,000,000 lb. a year. Our sales have steadily mounted and if we extrapolate the curve our sales next year should equal 7,000,000 lb. Shall we, as sales manager, warn the production department that we want increased capacity or not? If we ask for more capacity and do not sell the production, we are worse off than if we had not asked for greater output and lost additional sales. Very seldom is the curve of annual sales a steady curve of progress or decline. It jumps about and we are unable to discover all the reasons for such behavior. This makes prognostication difficult—so difficult, in fact, that a very great many sales managers make no attempt whatever to anticipate demand. If they sell all the factory produces, it is a good year. If they fall short, it is a bad year.

It is extremely unfortunate that this is the case. An analysis of sales data is not easy, but if it is intelligently done it will throw much light on the perplexing problem of future demand. The method of undertaking such analysis is too elaborate for a discussion of this kind, but it involves a study of deliveries of products to the different consuming industries or firms and a determination of the factors which have caused the variations in each case. It involves a study of other factors which affect the vigor of the consuming industry, and a careful estimate of general industrial conditions. There are very few firms in this country at the present time which did not have to take a staggering loss in the last 18 months because of a drop in the inventory value of the raw materials which they had in stock. If some one in the organization had only had his eyes on this very point—future demand—there would have been much less distress, for deflation would have taken place earlier. The fact that some firms anticipated the situation shows that it could have been done.

Markets; Evaluation and Differentiation

Markets are the medium in which the sales manager lives. He must therefore have accurate data as to the points of consumption of his product. This is usu-

ally recorded in one of two ways—card catalogs and maps. Maps, with numbers written in to indicate quantity of consumption at given points, are valuable visual aids in laying out sales campaigns. Catalogs are more elaborate and on the whole more valuable. Cards can be filed geographically and will usually carry all the information about an individual consumer. Such information is included as: The officers of the company; the products, quality and quantity consumed; their attitude toward the company's product; the sales made to the consumer, etc. The data are obtained largely through visits of salesmen, and it has already been pointed out that inaccuracies and omissions are unfortunately numerous. From the catalog, however, it is possible to gage the importance of specific territories.

This is the first step in planning for the amount of sales effort to be expended on a given place.

There are other factors which modify the decision, however, so that it is not always the point of maximum consumption where the maximum effort is expended. The first modifying factor is competing products. Competition in chemicals has been almost entirely a matter of price. In very few cases has there been intelligent study of consumers' needs and a definite bid for a market on a basis of quality or special fitness. It would be a source of distinct surprise to many manufacturers of chemicals to realize how much the specifications of even crude manufactured products have changed. This means simply that a firm which had specialized and advertised special qualities instead of stressing price only could have nearly monopolized the market. Examples are almost non-existent in chemistry. In a closely allied industry, however, there is tartar for textile mills—a large percentage of mill men know only Durfee's and use it exclusively. You may not believe it is better material, but the trade thinks so. It has been advertised as a specialty for years.

However, since competition is largely a matter of price in chemicals, the sales manager's decision to specialize in a given territory will be based on the knowledge that he is able to meet price competition. This, of course, involves an accurate knowledge of competing products, a knowledge of their strong and weak territories, accurate and immediate information of price changes. Such information cannot be obtained without many contacts in industry. A friendly broker often will furnish information. A consumer who is intimate with the firm, but who buys on competitive bids, is another source. Consumers who buy only from the firm often receive tempting concessions from the firm's competitors and report them. (Parenthetically, it might be added that the last class is almost non-existent now—the last 2 years has snapped almost every business tie. "Buy from Beelzebub if he has it cheap!" is the cry.) Finally, the company's salesmen are perhaps the most important source of such information.

Data gradually and continuously accumulate in the sales manager's office and he is thus able to make clearer and more definite decisions as to where his main effort will be expended.

How One Firm Picked Its Market

Unfortunately a very large number of firms still do not pick their markets—they drift into them. This situation is so prevalent that it is a distinct joy to discover a firm such as Blank & Co. This firm manufactures a product which is sold in relatively small quantities daily to the same people—in other words, a constant daily order is filled. This particular firm manufactures 2 or 3 per cent of the total quantity of product in that district. One other firm manufactures between 90 and 95 per cent of the total, yet that small firm is impregnable, and all because the general manager, who is also the sales manager, used his head. First, the quality is there and everyone knows it. Second, the small firm will not accept a large order. One large order might be a very appreciable percentage of the firm's production. The small company might have to make great concessions in order to keep the customer. The large competitor could easily arrange to give away the product in order to gain a large customer, but the small company distributes to scores of small consumers who are satisfied with the quality. The loss of one or even a dozen is not dangerous. The large company knows that any single small consumer is not worth trying to get because in a fight for small customers it would get much the worst of it. Three other larger companies have been absorbed by the large company in recent years, yet the small company is treated with respect and as an equal. That is sales policy and correct choice of markets.

Hundreds of other factors can legitimately influence the choice of markets. Transportation cost is a very obvious one. Selling cost is an often neglected factor. One consuming industry may be preferred to another because it has a constant and not a seasonal demand. Sometimes a special campaign must be directed toward an industry where the custom is to sign up for a year's contract during a definite month. Frequently the seller makes an effort to create such a precedent in an industry. It will scarcely be worth while to go further on this point. The real issue after all is not so much "How shall we pick our markets?" but to realize that there is a choice and that all consumers may not be the best customers. Nor does this include the credit aspects of the case, which will be discussed later.

Method of Selling

Shall We Deal With the Dealer?

How shall we sell? Shall our salesmen deal with consumer or broker, or shall we sell all of our output through a selling agent? This question is coming up for more serious consideration than formerly. Perhaps it was due to the lack of knowledge of or distaste for sales problems on the part of chemical manufacturers, but whatever the cause this particular question of sales policy received small consideration. Sometimes a dealer saw a good thing in it and contracted for the output or a large percentage of it. That settled the policy for that firm. It usually never occurred to it that by selling direct it might save the dealer's profit. Here again it is not the solution to the problem, nor even all of the factors that enter the problem that concerns us, but the fact that there is a problem.

Very frequently a dealer will have the confidence of a large consuming trade and that confidence he is justified in capitalizing by selling at a profit. The manufacturer from whom he buys could not compete in that field even with the same product at a lower price. A broker may have developed a reputation for locating the cheapest spot material. The manufacturer would have to offer big inducements to win the consumer

away from such a broker. Again a dealer by reason of his ability to distribute many products diminishes his selling overhead per unit and a manufacturer of a few commodities would find the additional profits gained by selling direct much less than might be expected.

However, it is more than likely that the balance is in the other direction. I mean that a firm is more apt to let it go via broker or dealer than tackle the difficult problems of selling, which problems if tackled would yield desirable and profitable results. Between the firm which sells 100 per cent of its output direct to the consumer and the firm which delivers its product to a selling agent there are all degrees of independence. There is no best way, although it is a safe generalization to say that under ordinary circumstances a firm should make an effort to sell direct to the consumer.

What's Your Price?

There are three general methods of determining selling prices. The first method sets a definite standard price for a carload of material (or other given unit) and allows a rebate for multiples of that unit. In other words, one carload at $4 per 100 lb., ten carloads at $3.90 per 100 lb. The second method allows no rebate per quantity consumption. The consumer of one carload gets the same rate as the consumer of 100 carloads. The third method is to set a minimum price below which salesmen cannot go and above which they will go as high as possible. Obviously the method adopted will depend on the type of consumer, the type of product and the temperament of the firm. All three are in use at the present time by firms of the highest reputation. Method 1 is frequently used when the producer sets a premium on the large consumer, and it is very obviously a concession to the large consumer. There is considerable justification in this procedure, for obviously the selling cost is less per unit product in the case of large consumers. Method 2 is often used by large firms which are in a position to dictate to a consuming industry and by firms which deal with an industry composed of many individual units. Method 3 is, I suppose, most widely used. It offers the greatest flexibility, although the tendency is generally toward the stability and prestige which a fixed price gives.

During the past 2 years any fixed selling policy has suffered. Too many firms have been hard up for cash to permit stability in anything except monopoly selling. Price cutting has been piratical and production cost has frequently been greater than selling price because of the imperative need of cash. This has forced even financially stable firms down to unhealthy price levels in order to meet a competition which they knew to be temporary because of their competitor's proximity to bankruptcy.

Even in normal times price regulation is apt to be unsystematic and not based on any accurate idea of production and selling costs but simply empirically upon what the market will bear. Such a policy is all right if the margin is high, but often a firm loses money without knowing it because it has no studied policy of price setting.

Selling Equipment

Entirely different considerations will govern the policy of the equipment house which sells to the chemical industries and in whose sale policies the chemical industry is vitally interested. There are two general classes into which we can group them. The first class includes those who sell once and for all time, and the second class has every hope of repeat orders. A thickener should last 10 to 20 years, whereas a pump may wear out in 90 days. It is obvious that the firm which sells a thickener will have to make a satisfactory profit on its first installation. The pump manufacturer could give away the first one if the purchaser would be willing to standardize on that make.

Terms

How many business houses there are which have given no thought to the terms of payment for their material. Someone they knew, perhaps a competitor, gave terms called 2/10/30, which means 2 per cent off for cash in 10 days, net 30 days. So they adopted that slogan. Perhaps they were strong enough to allow 60 or even 90 days before payment is due. Perhaps 1 per cent cash discount would have been sufficient. Almost certainly all of their customers should not have had the same terms. Usually the terms are a matter of form and the manufacturer pays little attention to them provided he gets his money some time. Very few if any chemical firms have adopted the admirable trade acceptance plan made possible by the Federal Reserve Bank. This subject will be discussed a little more fully under the Credit Department.

Sales Manager as Chief of Salesmen

So far we have discussed those functions of the sales manager which had nothing to do with the personnel of the sales department. In the average book on sales management this is given priority consideration and most of the discussion of the department is the organization of the personnel, the relation of the sales manager to the organization and the individual, and the personal qualities which should predominate in a sales manager.

Generalizations as to personal qualities are somewhat unsafe, for two very different personalities frequently make splendid records in the same sales manager position. A man may get the co-operation of salesmen by commanding and dominating them, by fraternizing with them, by setting an example of energy and enthusiasm. Who shall say one method is better? It is safe, of course, to say that a sales manager must have qualities of leadership. His salesmen look to him for guidance, encouragement, enthusiasm and reprimand. He must put his policy and his personality across to his men. The sales manager's task with personnel is really no more important than that of any other department head. Much more has been written about it, because the results of failure or success are more immediately obvious. For that very reason they are more easily remedied and therefore not so insidious nor ultimately so vital as the personnel problems in the factory, for example, where the personnel problem is not considered so vital. The most desirable result obtained from so much discussion of the sales manager's personnel problems has been the focusing of attention thereon. It is now without question the healthiest phase of sales manager work. The average sales manager has his salesmen well organized, contented and on their toes. When a sales manager fails, it is probably not because he has not attended to problems of personnel.

In discussing salesmen we mentioned the relation of

the individual to the department and the methods of keeping in contact. It is necessary only to remember that the salesman is a unit in the general campaign and a person as well. The sales manager, then, has to utilize that personality in the general scheme. Multiply that by the number of salesmen and you have the sales manager's personnel problem. A steadfast belief in the relative futility of writing about the way to handle men will cut this discussion short. A few days' observation of a man who is successful in dealing with men is worth infinitely more than any treatise on the subject.

Unlike the purchasing agent's job there is no almost universally applicable system which the sales manager can follow. Unless a system is designed for the specific problems of that company and possessed of considerable flexibility, it is certain to prove inadequate to the needs of the sales department.

A big job and a vital one! Why don't you try selling? You might make a success of it.

Duplex Iron in a German Foundry

In commenting on a paper read before the Baltimore meeting of the American Electrochemical Society by George K. Elliott, entitled "Cast Iron as Produced in the Electric Furnace, and Some of Its Problems," Richard Moldenke read an abstract of a recent paper in *Giesserei Zeitung* on the methods recently installed in an iron foundry in Plauen.

Nothing but low-grade cheap scrap—of which 20 per cent is steel—is charged into the cupola; 5 tons of liquid iron is transferred to a basic electric furnace. Four or five heats are made each day. Iron is held under the ordinary carbide slag about 60 minutes, ferrosilicon and manganese rabbled in, the entire contents poured into a large ladle and the thin slag carefully skimmed. Castings poured from this metal produced very few defectives, showed entire freedom from pinholes, low shrinkage, and no hard spots; the iron was tough but not hard, machined easily, and its strength was increased 30 to 40 per cent. Comparative analyses:

	Cupola Iron	Electric Duplex
C	3.35	3.0
Si	1.65	2.15
Mn	0.35	0.55
P	0.06	0.06
S	0.23	0.05

Low phosphorus in the cupola iron is to be expected in Germany. Sulphur has actually been reduced to 0.01 when molding troubles have held the metal in the electric furnace for an unusually long period.

Cost tables in the original article indicate that the very low price of poor scrap enables such a process to compete with direct cupola melting. Current consumption averaged 160 kw.-hr. per ton of metal.

Effect of Back Pressure on Oil Production

In the study of the effect of regulated back pressure on oil production, the Bureau of Mines has found that wells being produced under several pounds back pressure are not declining as rapidly as other wells in the field. This investigation is of especial interest, as if it can be demonstrated that pressures up to 10 to 15 lb. can be carried on the wells without affecting the production, it will result in saving large quantities of gas, now wasted, by producing the wells at atmospheric pressure.

Timber Preservation Grows in Importance

The increased demand for permanent timber structures is shown in a recent report of the Service Bureau of the American Wood Preservers' Association. Over 2,400,000,000 board feet of timber for various purposes were pressure treated in 1921 by the 122 wood-preserving plants in operation throughout the United States, thereby surpassing the 1920 record by nearly 17 per cent. Approximately equal amounts were treated with coal-tar creosote and with zinc chloride, the standard wood preservatives. To treat this wood 51,375,360 lb. of zinc chloride, with an absorption of ½ lb. per cu.ft., and 79,384,326 gal. of creosote, with an absorption of 5 to over 20 lb. per cu.ft., were required.

Ease of handling and the permanence of well-treated wood at low cost are given as the reason for the increased demand.

Production of Phosphate Rock in 1921

According to conservative estimates made by the United States Geological Survey from the incomplete returns available April 1, the quantity of phosphate rock sold in the United States in 1921 was about 1,968,000 long tons, valued at $10,928,300, as compared with 4,103,982 long tons, valued at $25,079,572, in 1920.

The total production of Florida was approximately 1,675,000 long tons, valued at $9,036,000. Tennessee followed with an approximate total of 293,000 long tons, valued at $1,892,300, which included a small quantity of brown rock from Kentucky. The Western States were reperesented by only one producer, and South Carolina dropped out entirely.

The general business depression of 1921 is illustrated in the decline of the production of phosphate rock. The decrease in the selling price of agricultural products, combined with the high freight rates, prevented farmers from purchasing fertilizer, and the low rates of exchange discouraged exporters in the industry.

Porosimeter Used in Ceramic Investigations

The porosimeter developed in the studies of the oxidation of ceramic wares during firing, being conducted at the Columbus, Ohio, station of the Bureau of Mines, has proved a great aid in the control of the latter part of the burn, more especially for paving blocks where a low porosity is essential. A preliminary survey of the relation among porosity, vitrification and rattler test has been made.

Production of Gypsum in 1921

According to conservative estimates made by the United States Geological Survey from the incomplete returns available April 1, 1922, the quantity of gypsum mined in the United States in 1921 was approximately 2,870,000 short tons, as compared with 3,129,142 tons in 1920. The combined value of the crude and calcined gypsum sold was approximately $20,820,000, as compared with $24,533,065 in 1920.

Bureau of Mines Work on Bentonite

Work has been completed at the ceramic experiment station of the Bureau of Mines, Columbus, Ohio, on bentonites, which are probably aggregates of alkaline hydrated silica and kaolinate. Some of their characteristics are conchoidial fracture, high colloidal content, high water of plasticity and drying shrinkages. Their burned color varies from light buff to brown.

Atmospheric Pollution From Sulphuric Acid Plant Fumes

A Discussion of the Importance of the Fume Problem to the Chemical Manufacturer From the Standpoint of Public Health, Legislation and Economical Operation—Work of the Atmospheric Pollution Committee of the American Institute of Chemical Engineers

By JAMES R. WITHROW
Professor of Industrial Chemistry, Ohio State University

MOST sulphuric acid plants in America are remarkably free from atmospheric pollution, when one considers the ease of escape of the gases and escape products of this industry. The long history of the atmospheric pollution question in the smelting industry is well known. The chemical industries have never been accustomed to such deliberate pollution since the early days of the old Le Blanc soda process. In the first place, the chemical plants are rarely in isolated places, where such wholesale pollution would be a temptation. In the second place, the very nature of the chemical industries makes the conservation and utilization of the polluting gases and escape products of pecuniary importance. The smelting industry, too, is now rapidly stamping out the fume evil.

This does not mean that thoughtless, careless or even criminal pollution of the atmosphere never happens in the chemical industry. Probably no one could successfully maintain this. There will always be thoughtless, careless or even criminal management, as well as workmen. It is inevitable, however, that the number of such operators will gradually approach a minimum. Nevertheless, it is just these few who give occasion to those who, from whatever motive, attack the industries of such a nature that atmospheric pollution is at all possible by them. It must be admitted that the operating management can at times become so absorbed in "production against time" that a "little" escape will be overlooked or even winked at.

Most chemical companies, however, give this matter serious attention. Some of these maintain a staff to control their "escape" and reduce it to the utmost. In spite of such precautions, the growth in density of population makes this whole matter one of increasing concern. It is for the manufacturer to increase his vigilance against "escapes" and give more publicity to his real interest in the matter.

Chemical Manufacturers Neglect Publicity

It comes as a shock when one is told, as the writer has been, by an officer of a state Board of Health, that chemical manufacturers have no interest in the health welfare of their men or community. This opinion was doubtless held in good faith and may even have been true of a few plants, for at one time it was more justified than it is now. However, unless the writer's observation has been misleading indeed, it does not represent the spirit of any great group of chemical manufacturers today.

This allegation of non-acceptance of responsibility in the chemical industry is probably due to the failure of manufacturers to realize the desirability of publicity on the subject. This neglect has been a mistake. Publicity, if sincere, eventually works for good and promotes public confidence. It works both ways too, for it will make it easier for the manufacturer to cooperate with government in such matters for the public good. The slogan, "The less legislation the better, other things being equal," certainly holds true for business. Nothing would be worse than ill-advised or drastic legislation which ultimately would result from a state of ignorance and lack of mutual confidence on the side both of industry and the public. Litigation and injunction are all too frequent at the present time. Manufacturers, therefore, must take even more advanced steps than heretofore.

Importance of the Sulphuric Acid Industry to the Public

The importance of conserving the sulphuric acid industry by helping it to eliminate its fume nuisance troubles which so frequently damage agricultural interests and antagonize urban ones speaks for itself. The elimination of fume nuisance is all the more necessary because of the very fact of this acid industry's growing importance in chemical manufacture, in the pickling of iron and steel before finishing such products as wire, tin plate and galvanized products; its importance in the refining of petroleum and, most of all, because of the quantity used, in the manufacture of superphosphate fertilizer for the development of agriculture.

The desirability of greater uniformity in fume nuisance legislation has been pointed out by Baskerville. There is need of a better chemical knowledge of means of detecting fume escape and the extent of atmospheric pollution, to help plants defend themselves against polluting the neighborhood atmosphere, as well as against losses in production. Work is in progress on suggested improvements of current methods and certain investigational studies in this field are known to be under way, but greater publicity should be given to the experience of the industries with these methods for the benefit of industry as a whole. Satisfactory methods and standards are still uncertain matters. We should arouse comment, suggestion and criticism calculated to bring out every point of view and all available assistance in the abating of fume nuisance near sulphuric acid and other plants. Before positive legislation is passed regarding the operation of such plants, it behooves the chemist, chemical engineer and manufacturer to anticipate such action and to furnish proper and adequate methods for establishing the standard to be adopted.

The importance of sulphuric acid manufacture to agriculture and the arts makes the public interested in conserving this acid industry. This does not warrant the industry in maintaining a nuisance by its escaping

fumes. In fact, the public will insist upon not being imposed upon and, therefore, as the population concentrates in our Eastern and other manufacturing centers the problem must be handled with candor and expedition. The acid maker must be a good citizen with his plant as well as individually. He cannot hope to rest long on his accomplishments like the Western smelter manager who once said that he had no more court troubles since he had been able to show that he had purchased the same fume-poisoned horse nearly two dozen times and each time from a different farmer upon whose premises it was alleged to have died from smelter fumes—a familiar form of graft known in the West as "smoke-farming."

Even when such acid plants have been unwisely placed, though they are not excused in law for creating a nuisance, we probably cannot insist upon their closure or removal. The loss in such an event would be heavy and the community itself would suffer through loss of work for labor and through curtailed production. We must, therefore, meet the situation squarely in good faith and abate the nuisance entirely or at least reduce it to a minimum.

What Constitutes a Nuisance

The public recourse to our courts of justice tends to hold in check a general pollution of the atmosphere or the creation of a general nuisance. What constitutes a nuisance in this country depends on the state in which the question arises. Baskerville has suggested that the ideal remedy would appear to lie in federal legislation controlling the industries, defining the term "nuisance" in connection with fumes from sulphuric acid manufacture and to what extent atmospheric pollution can be permitted without creating such a nuisance. Whether this can be accomplished in our present stage of development in this country is debatable. As the situation now stands, the sulphuric acid industry in the United States is hampered by the varied interpretation in our courts of the term "nuisance."

To hold in check both the inefficient operator of such plants from running wild on the one hand and the unscrupulous lawyer from taking advantage of the present legal conditions on the other hand, it might very well be that federal legislation would be the eventual recourse.

The chaos in this country at present is readily understood when the decisions made in the different states regarding what constitutes a nuisance are reviewed. Local legislation appears in a hopeless situation. Baskerville[1] has pointed out that New Jersey might have one interpretation while New York might have another and so on throughout the Union, ranging in interpretation from one extreme to another. Decisions in Iowa, Massachusetts, Texas and Vermont held that a noxious trade may be a nuisance if it inflicts serious discomfort on people passing by on a public highway no matter how distant from the source of nuisance. On the other hand, the City of New York imposes a stipulated fine for creating a nuisance, but the fact that an order of arrest cannot be issued before one month from the date of initiation of nuisance, and this nuisance may continue until the end of the month, when the fine be assessed, makes the ordinance ridiculous.

The United States appears far behind Great Britain, for instance, in the uniform legislative control of escaping fumes from chemical plants. As early as Jan. 1, 1864, a British Parliamentary act was in operation, not stopping, but regulating, the amount of hydrochloric acid gas escaping into the atmosphere from plants using the Le Blanc process. The act was to lapse in 1868, but at that time it was made permanent. In 1874 sulphuric acid wet process copper works were included, without pollution limits. Two years later a committee of alkali manufacturers was appointed to watch the proceedings of the Royal Commission, which was investigating noxious gases generally. In 1882 an enactment was made that industries manufacturing "chemical manure," salt, nitric acid, sulphate of ammonia, chlorine and sulphuric acid, and those depositing or discharging alkali wastes and creating nuisances from fumes, be added to the list of industries to be inspected and regulated. The object of the act was to prevent damage to the health of the people in the neighborhood of such establishments. Since 1898 the chief inspector has especially emphasized the sulphuric acid industry in his annual report due to the numerous complaints.[2]

The Alkali Commission, self-appointed, also assumed control in England of investigations on methods of analyses of these acid gases and fumes.[3]

The act of 1907 requires that the samples must be taken from the chimney just after the gases leave the Gay-Lussac tower. This obviously gives one source of information necessary in efficient operation, but leaks occurring before the chambers cannot be checked up readily, since the quantity of acid produced from the tonnage of sulphur or ore burned would have to be known to detect these leaks by using this method alone. The quantity of SO_3 and SO_2 escaping from the burner room or leaks in a Glover tower or the chambers, for instance, may be many fold greater than the SO_2 or SO_3 found in the chimney by such a governmental regulation inspection system.

In Germany explicit uniform legislation does not exist. The usual requirement is that the gases from the Gay-Lussac towers shall not contain more than a certain proportion of SO_2 according to the locality. In some places in Prussia the gases may not contain more than 0.02 per cent SO_2 by volume as stated by Ingalls.[4] Wislicenus points out that the danger of such regulations in the hands of local authorities is that politics may play too strong a hand in the proper exercise of controlling atmospheric pollution.

What Fume Control Could Accomplish

It is evident that the control of fume escape from sulphuric acid plants is important from the following points of view, which illustrate what it would or might accomplish: (1) Betterment of health conditions in the neighborhood; (2) elimination of damage to vegetation; (3) elimination of litigation; (4) improvement of production yields.

The effect of these gases on the workmen is very difficult to ascertain. After a short time the men become accustomed to the effects of the gases and they appear no longer irritated by them. The ultimate effect on their health, however, is not known, since no study

[4] *Mineral Industry*, vol. 14, p. 682, 1907.

appears to have been made thereon and the matter has been given little publicity.

The good accomplished in Great Britain by acts of Parliament and by the Alkali Commission due to co-operation does not seem to have had its influence in America except to the extent it may have raised general commercial efficiency of operation. The appointment of such a body or commission by manufacturers in this country, even if our legislative bodies do not take action, should result in the saving of large sums of money as well as eliminating litigation and friction. The good work of the Selby Smelter Commission carried out under the direction of the U. S. Bureau of Mines, in investigating the nuisance created by the Selby Smelter & Lead Co. of Contra Costa County, Cal., due to dust, SO_3, H_2SO_4 fumes and SO_2 mainly, with small amounts of lead and arsenic compounds, was a valuable contribution.

Losses in Acid Plants

We should not feel that this problem exists, however, only among smelters. Sulphuric acid plants are more frequently concerned than in the past. That the fume problem from sulphuric acid plants is a real one may be deduced from the operation data of a certain sulphuric acid plant, which has recently been sued in court for damage done to surrounding farm lands. During the period from Jan. 1 to June 30, 1920 (inclusive), 13,936 tons of chamber acid was produced. On the basis of sulphur burned, for the same period of time 902 tons sulphuric acid was lost. Therefore it was calculated that about 229 tons of sulphur may have been dissipated into the air through leaks in chambers, backfires in burners or through the exit flue. This was a percentage loss of 6.06 per cent on the basis of sulphur burned, or a pollution of the air to the extent of 5,046 lb. of SO_2 per day, or in the neighborhood of 30,000 cu.ft. if all the loss followed this route. As a matter of fact, it is extremely improbable that high exit gas accounts for all this loss, although undoubtedly much did go this way. The loss at this plant is high, but not necessarily much above the average practice throughout the United States, though at most plants the loss is probably not due to any great extent to SO_2 escape. Thorpe[5] states that the yield in practice from burning brimstone averages 96 to 98 per cent.

Efforts at Amelioration

With respect to amelioration of SO_2 escape, smelter experience is suggestive. In some instances court rulings have regulated the extent of pollution by ordering curtailment of production so that the amount of SO_2 pollution may not exceed a specified quantity. Other plants have striven to keep down the ratio of SO_2 in the air by dissipation of gases by means of large stacks and by the use of the Wislicenus lattice-top smokestack.[6]

Chemical absorbents such as water, sulphuric acid, metallic oxides and hydroxides, dicalcium phosphate, silica gel, lime and limestone, moist scrap iron, charcoal and such materials have been suggested, but not extensively put to practical use for rather obvious reasons. Because of the high dilution of the SO_2 gas, mechanical water concentrators have been suggested by Wedge[7] in addition to the chemical absorbents mentioned above.

Even if any one of the above were a commercial success, as the Tennessee cases undoubtedly are, smelter fume solution would not necessarily solve the sulphuric acid fume problem in its entirety. Enforcement of efficient operating practice would probably be more efficacious.

Frequently bad operation appears to be the cause of excessive fume distribution over a community by a plant using SO_2 or SO_3 in some form. Even in efficiently operated plants, however, as indicated by the chief inspector's report of the alkali works regulation acts, the fume problem assumes varying degrees of annoyance and has not been solved. Some plants in this country are so well managed that they are seldom if ever a nuisance. In operation a leak may escape notice of the employees, because they have become so accustomed to these odors, while the annoyance to persons outside of the plant may be considerable. Therefore the sense of smell cannot be relied on. Proper methods of control in the plant, able to detect any undue loss or escape of constituents, are essential in efficient operation of sulphuric acid plants.

The analysis of the neighborhood atmosphere is necessarily the first consideration in any investigation of this kind. At present the iodine and $KMnO_4$ oxidimetric and the alkalimetric methods are employed in attempts to detect and evaluate escape of gases and check operation of plant. These methods, however, are known to be not as satisfactory as they should be.

Active Interest Among Chemical Manufacturers in the Fume Question

The New Orleans meeting of the American Institute of Chemical Engineers furnished a good index of the keen interest of chemical producers in this whole question of atmospheric pollution from chemical sources. The discussion of the sulphuric acid fume problem at that meeting was one of the best discussions drawn out by a paper before the Institute for several years. Many ideas and points of view were brought out. The Institute appointed a committee to report upon the matter. Among the suggestions in the discussion of this subject in the Institute and the various meetings of its committee, a few should be mentioned to show the nature of the interest aroused.

1. It was suggested that a co-operative committee of the chemical industries subsidized by the manufacturers would enable America to progress rightly in the question and assist in solving the fume nuisance not only from sulphuric acid plants but from all chemical industries evolving SO_2 and other noxious gases. If someone does not initiate this, it will come by bunglesome legislation; nothing can stop it. Therefore the sooner the question is met the greater convenience the chemical industries will be to the communities at large and the better will trouble with these communities be evaded.

2. It was brought out that this whole problem is closely connected with that of industrial health hazards, which is receiving able attention. The economic and business relation to the community of this fume question makes it a broader one than merely health hazard, important as that matter may be.

[7] *Eng. and Min. J.*, vol. 95, p. 628, 1913; *J. Soc. Chem. Ind.*, vol. 39, p. 370, 1920.

3. Attention was called to the experience at Ducktown, Tenn. No SO_3 was found with the SO_2 in the stack gases if the barium chloride absorption solution was boiled in the dark, upon an electric hot plate. An SO_2 concentration of 342 parts per million within 50 yd. of the stack dropped to zero at 2 miles distance. The Selby Smelter Commission method was used in the 6-liter samples rather than 24-liter samples. *N*/500 iodine gave a sensitiveness of 0.18 part per million of SO_2.

4. The psychological and real estate trading features of complaints were brought out in cases where plants even moved into a wilderness and had towns subsequently grow up adjacent, entirely dependent upon the industry.

5. Damage to trees from sulphur derivatives in power plants' stack gases due to sulphur in the fuel was pointed out from Cleveland and other cities. The astoundingly great volumes of SO_2 in any metropolitan district from the sulphur in the coal consumed was also emphasized.

6. It was pointed out that the problem should be solved rather than dismissed as excusable or unavoidable. The public will not long stand for such an attitude.

7. It was pointed out that enforced stoppage of pollution makes the manufacturer more attentive to production efficiency, and in spite of his initial protest and resistance, legislation eventually works out in many cases in his favor. The huge Tennessee sulphuric acid production is a case well in point, as is also the making of sulphuric acid from liquid sulphur dioxide at the Tacoma smelter.

Work of the Committee of the Institute of Chemical Engineers

Subsequent to this discussion at New Orleans, President Wesson of the Institute of Chemical Engineers appointed a committee to take up the suggestions and make a report of action the Institute should take in the matter. This committee carried on active correspondence. Two of its members made long trips, one to Utah and the other to the Tennessee copper region. The committee gathered many data and many conflicting suggestions. After 10 months' work all preliminary disagreements were finally ironed out and such material as could be unanimously agreed to was presented to the Institute, where the report was unanimously adopted and the committee discharged.

This final report incorporated all of the essential suggestions of a preliminary tentative report, which was presented at the Detroit meeting of the Institute,[8] and that report was materially strengthened. All members of the committee took an active interest in its work, and it is believed that the report of the committee constitutes the most advanced position taken by a body of chemists or engineers on the fume subject in this country.

The matter of sulphuric acid plant fume was not the exclusive consideration, but the committee was selected entirely of men interested in this question, because the fume question from sulphuric acid plants has to do with our most fundamental acid industry. It is quite possible that further suggestions could have been adopted by the committee and still more advanced position taken. Nevertheless, the position taken is a substantial one. There is now definitely on record the keen interest which manufacturing chemists possess in this matter, and the report of the committee places squarely upon the shoulders of the Manufacturing Chemists' Association the responsibility for further advances and action in this matter. It is believed that that organization will not shirk its responsibility or ignore its part, since its members officially represent manufacturing organizations.

It is particularly worthy of note that while there was strenuous difference of opinion among members of the committee as to modes of action, yet the reasonable attitude of every member, because of the keen interest in improving the situation for the benefit of both the public and the industries, resulted in the inevitable unanimous agreement upon the report.

Committee Report

Extracts from the report as adopted by the American Institute of Chemical Engineers at its Baltimore meeting, December, 1921, follow. Its details will show more fully than any discussion could the real advances that were made by this committee:

> To the American Institute of Chemical Engineers:
>
> Gentlemen: Your committee begs leave to report:
>
> That we have confined our attention to atmospheric pollution by chemical manufacturing processes only.
>
> Your committee is aware of research being carried on by various investigators along the line of atmospheric pollution in connection with smelter fumes, and it urges these to proceed with the publication of their results at the earliest practicable date for the benefit of the chemical industry and the public.
>
> Your committee recommends that the Institute should stand for the principle that the public is not interested in the chemical efficiency of any particular chemical process liable at times of causing atmospheric pollution but only in the question as to whether it, the public, is in fact being injured. For instance, an arbitrary limit on the number of grains of SO_2 per cu.ft. in an exit gas means nothing unless taken in connection with the height of the exit above the surrounding country capable of being injured, having clearly in mind that the essential factor is the actual concentration at the area of possible damage. Any contemplated legislation or regulations should be drawn up having these facts clearly in mind.
>
> We call to the attention of the Institute that, in the Anderson smelter case at Salt Lake City (as the most recent notable smelter case), the court recognized the conclusions of Dr. Swain's committee[9] as to facts of the limit of injury to vegetation by sulphur dioxide. This concentration was established by careful investigation, such as that by Dr. O'Gara. The most notable conclusion thus established and accepted in court was that in order to produce injury to vegetation by sulphur dioxide it is necessary to have a concentration of at least one part per million by volume for a period of 3 hours in contact with the plant under optimum conditions. Swain's report states that the optimum conditions would be: "It is now conceded that there are four predominant factors which operate in this connection: (1) Humidity, (2) light, (3) temperature, (4) duration of exposure.
>
> "Of these four factors, that of the relative humidity of the atmosphere is perhaps the most important. The concentration of sulphur dioxide, which is necessary to produce markings on the less resistant plants when the relative humidity is very low, is seven or eight times that which is necessary if the humidity is very high. . . . Light is also one important factor. During the

[8] Chem. & Met. Eng., vol. 21, No. 1, July 6, 1921.

[9] Report of Dr. Robert E. Swain as Commissioner of the United States District Court for the District of Utah in the case of John A. Anderson et al., plaintiffs, vs. American Smelting & Refining Co. and United States Smelting & Refining Co., defendants. This report dated Feb. 28, 1921, and addressed to the Hon. Tillman D. Johnson of the United States District Court, Salt Lake City, Utah.

See also Chem. & Met. Eng., vol. 22, No. 25, p. 1145, June 23, 1920; vol. 24, No. 11, pp. 459 and 463, March 16, 1921; vol. 24, No. 16, p. 709, April 20, 1921.

night-time plants require much higher concentration of sulphur dioxide to produce typical markings than they do in daylight, other conditions being constant. . . . Temperature is a third factor, but of importance only in that a temperature of 5 deg. C. is a necessary optimum condition. . . . "It is now generally conceded that a concentration of at least one part per million over a period of 3 hours is necessary to produce undoubted injury to the most sensitive crops."

The committee urges that all chemical manufacturers recognize the far-sighted policy of settling promptly and out of court all just claims, and fight to the limit all unjust claims because of the far-reaching damage which may result not only to themselves but to the entire industry by precedents accidentally established through erroneous court decisions.

We recommend to the attention of the Institute and to operating engineers and manufacturers the extensive studies made in the various smelter fume cases of the country, that much suggestive help and guidance may be obtained as a result of earnest and exhaustive research on the subject, and that the trend of court opinion and decision in these cases may be obtained not only in regard to atmospheric pollution in general, but particularly in regard to sulphur dioxide and sulphuric acid fumes. A partial list of sources of information in this field is as follows:

1. Report to Supreme Court of the United States—October Term, 1914. State of Georgia, plaintiff, vs. Tennessee Copper Co. and the Ducktown Sulphur, Copper & Iron Co., Ltd. By J. T. McGill of Vanderbilt University.
2. Report to Supreme Court of the State of California in and for the County of Solano, 1915. People of the State of California, plaintiff, vs. Selby Smelting & Lead Co. United States Bureau of Mines Bulletin 98, Report of Selby Smelting Commission.
3. Report to United States District Court of Utah, Feb. 28, 1921. John A. Anderson et al., plaintiffs, vs. American Smelting & Refining Co. and the United States Smelting & Refining Co. By Dr. R. E. Swain of Leland Stanford University acting as commissioner of the court.

Your committee is glad to report, as an evidence of the widespread interest in the problem of atmospheric pollution, that the advisory committee on atmospheric pollution of the Meteorological Office of the British Air Ministry in London have written through their superintendent, Dr. A. S. Owens, to Dr. Charles Baskerville of your committee, discussing his work on the detection of sulphur dioxide and offering to co-operate on any program which your committee or the Institute might inaugurate, to save time from overlapping of effort.

As an indication of the real interest of this committee in the problem, it needs only be mentioned that of the committee members, Henry Howard was formerly of the Merrimac Chemical Co., and now of the Grasselli Chemical Co.; A. M. Fairlie is consulting chemical engineer to the Tennessee Copper Co. in sulphuric acid development at Copperhill, Tenn.; C. B. Clark is in charge of fume problems of the General Chemical Co.; A. E. Marshall is consulting chemical engineer and former manager of the Davison Chemical Co., Curtis Bay, Md., for many years experienced with British practice; the late Charles Baskerville was chairman of the committee on occupational diseases of the American Chemical Society; A. B. Conner is chemical engineer of the Detroit Chemical Co.; James R. Withrow, chairman, is in charge of the investigations of the sulphuric acid fume problem work of the Engineering Experiment Station of the Ohio State University.

Sulphur, Pyrites and Sulphuric Acid in 1920 and 1921

The quantity of sulphur produced in 1920—1,255,249 long tons—was the largest produced in any year except 1918, when the output reached 1,353,525 long tons, according to the United States Geological Survey. The shipments in 1920, amounting to 1,517,625 long tons, exceeded those of any other year. Two mines in Texas and one each in Louisiana and Nevada furnished all the sulphur produced in this country in 1920. The value of the shipments in 1920 is estimated at $30,000,000. The sulphur produced in 1921 amounted to 1,879,150 long tons, which is about one-third more than was produced in 1920. On the other hand, the shipments in 1921 were nearly one-third less than in 1920, amounting to only 954,344 long tons, as against 1,517,625 long tons. It is therefore evident that large stocks of sulphur are now on hand. In 1920 and 1921, as in former years, more than 99½ per cent for the sulphur produced in this country came from Texas and Louisiana.

The exports of sulphur in 1920 amounted to 477,450 long tons, valued at $8,994,350, and in 1921 to 285,762 long tons, valued at $4,524,788, according to records of the Bureau of Foreign and Domestic Commerce of the Department of Commerce. It is therefore apparent that the exports of sulphur decreased about two-fifths in 1921 and that there was a drop in value of $3 a ton from 1920 to 1921. The imports of sulphur dropped from 136 long tons in 1920 to 50 long tons in 1921, and the value decreased about $7.50 per long ton.

Pyrites

The production of pyrites in 1920 was 310,777 long tons, valued at approximately $1,597,000. This quantity was almost twice that produced in 1921—157,118 long tons—estimated to be worth about $700,000. In 1920 California led in production, contributing 128,114 long tons, which was only a few hundred tons less than in 1919, and 98,252 long tons in 1921. The average value per ton for the total pyrites produced in the United States was somewhat less in 1921 than in 1920, being about $5 for 1920 and $4.45 for 1921.

The reports received from producers indicate that the market for pyrites has been very poor for the last 2 years, because the manufacturers of sulphuric acid, who have heretofore been the principal purchasers of pyrites, are now using more native sulphur, which is not only cheaper but more easily handled. The slack market is also reflected in the imports of pyrites, which fell off about one-third in 1921 from those in 1920. The imports in 1920 amounted to 332,606 long tons, valued at $1,660,832. About 200,000 long tons came from Spain, 100,000 long tons from Canada, and small quantities from France, Cuba, Chile and Hongkong. The imports in 1921 amounted to 216,229 long tons, valued at $818,852. The price per ton of the imported ore was about $1 less in 1921 than in 1920.

Sulphuric Acid

Sulphuric acid was produced in thirty states in 1920 to the amount of approximately 5,600,000 short tons, of 50 to 66 deg. Bé. computed as 50 deg. Bé. acid. The estimated value of this acid is $59,000,000. Production of the stronger acids amounted to 502,970 short tons, valued at approximately $10,600,000. Figures relative to the production of sulphuric acid in 1921 will be compiled by the Bureau of the Census.

Records of the Bureau of Foreign and Domestic Commerce show that 14,494 short tons of sulphuric acid, valued at $738,188, was exported from this country in 1920, and 5,409 short tons, valued at $87,979, was imported.

Studies in the Carbonization of Coal: Characteristics of Low-Temperature Coal Tar*

A Continuation of the Study of the Composition of a Commercial Low-Temperature Tar—The Nitrogen Bases, Alcohols, Sulphur Compounds, Saturated, Unsaturated and Aromatic Hydrocarbons—Review of the Results Obtained by Previous Investigators

BY JEROME J. MORGAN AND ROLAND P. SOULE
Department of Chemical Engineering, Columbia University

EDITOR'S NOTE: In the preceding section of this report, which was published in CHEMICAL & METALLURGICAL ENGINEERING for May 17, 1922, pp. 923 *ff.*, the authors outlined a scheme for the examination of low-temperature tars and compared the composition of a commercial tar (Carbocoal) with that of coke-oven and gas works tars. In the present installment, the nitrogen bases, alcohols, sulphur compounds and hydrocarbons present in low-temperature tar are given detailed discussion similar to that accorded the phenols in the previous paper.

The Nitrogen Bases

Percentage of Bases. The percentages of bases in low-temperature tar were determined in four of the five phenol-free fractions of the tar distillate by a gravimetric method similar to that used for the tar-acids (*cf.* Fig. 1). Since the quantity of bases contained in the first fraction (20-173 deg.) was too small for quantitative extraction with 20 per cent sulphuric acid, however, recourse was taken to a titration method, using methyl orange as indicator.[26]

The results of these analyses are recorded in Fig. 7, where the percentages of bases in each tar-fraction are plotted against the average boiling point of that fraction during distillation. The rapid rise of this curve indicates that the pitch probably contains a greater quantity of these compounds than the distillate.

Examination and Classifications. The crude tar-bases, recovered and purified as indicated in Fig. 1, formed a non-viscous, dark brown liquid mixture with a strong odor of pyridine. Having ascertained that the decomposition resulting was negligible, a sample was rapidly distilled to dryness to obtain a clear distillate for the later tests.

The bases showed a negative carbylamine reaction, and with nitrous acid evolved insufficient nitrogen to be measured. Primary bases could therefore be present only to a negligible extent. A saturated solution of sodium nitrate precipitated a mixture of nitrosamines from a hydrochloric acid solution of the bases. After purification their nature was verified by the Liebermann and diphenylamine reactions. The tests were both pronounced, and demonstrated the presence of secondary amines.

Hinsberg's benzene-sulphonyl-chloride method was used to separate the secondary from the tertiary bases. A precipitate of sulphonamides was formed, which was completely insoluble in alkali. On acidification, 80 per cent of the sample passed into the acid layer. The Carbocoal bases, therefore, contained no primary, about 20 per cent secondary, and 80 per cent of tertiary bases. The purified tertiary bases recovered by this method and the sulphonamides prepared from the secondary bases rapidly reduced a 1 per cent aqueous solution of potassium permanganate, indicating unsaturation.

Fractionation and Specific-Gravity Determinations. The density of the mixture of low-temperature bases was 0.993, and that of the high-temperature bases was 1.060 at 15.5 deg./4 deg. C. Comparative fractional distillations showed that the bases from low-temperature tar are lacking in any preponderant single component analogous to quinoline in the high-temperature

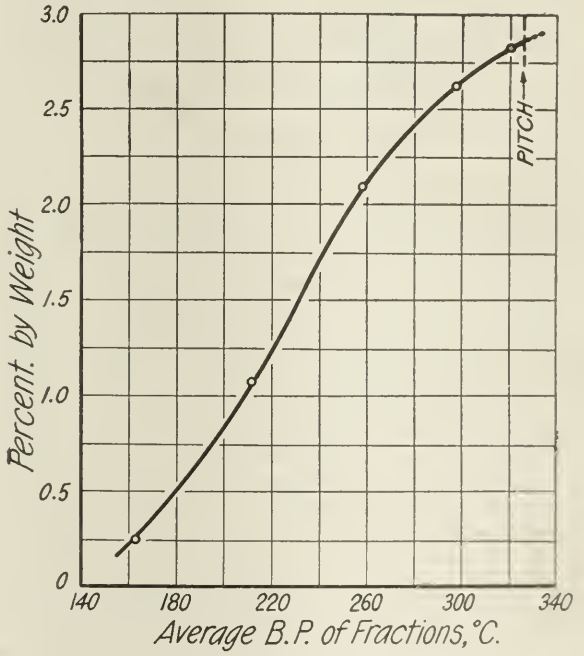

FIG. 7—RELATION OF BOILING POINT OF TAR FRACTIONS TO PERCENTAGE OF BASES CONTAINED IN EACH

bases. Following the practice employed with the tar-acids, the bases were re-fractionated with a 10-in. Vigreux column, and six fractions obtained in each case. The specific gravities of the fractions, determined after drying over solid potassium hydroxide, are plotted in Fig. 8 against the corresponding average boiling points (determined graphically). These curves demonstrate that the low-temperature bases are in general quite different in composition from those in

*Condensed from a thesis presented by Roland P. Soule in partial fulfillment of the requirements for the degree of Doctor of Philosophy in the Faculty of Pure Science of Columbia University in the City of New York.

[26] W. Gluud and P. K. Breuer, *Ges. Abhandl.*, vol. 3, p. 227 (1918).

ordinary coke-oven and gas-works tar. This is contrary to the case of the tar-acids (Fig. 6).

The smallest difference in density between the low- and high-temperature bases occurs in the low-boiling fractions. The first fraction of the low-temperature bases had a strong odor of pyridine, and was the only fraction appreciably soluble in water. With α-dinitrochlorbenzene it showed the characteristic red-violet color of the pyridine derivative. In common with ordinary tar, therefore, low-temperature tar contains some pyridine.

In the distillates between 230 and 260 deg. the densities of the bases are about 0.07 lower than those of

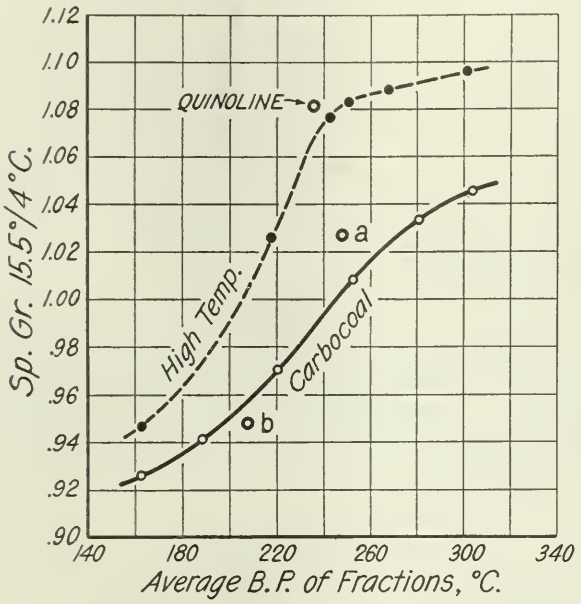

FIG. 8—BOILING VS. SPECIFIC GRAVITY OF BASES

the corresponding fractions of the quinoline-containing high-temperature bases. This difference indicates in the low-temperature bases a greater degree of hydrogenation of the nucleus, the presence of aliphatic side-chains of higher molecular weight, or both. Such compounds are exemplified by point *a*, N-methyltetrahydroquinoline and by point *b*, 2 methyl, 3 ethyl, 1:4:5:6 tetrahydropyridine. Since unsaturated bases are also present, compounds of the type of dihydroquinoline may occur in the mixture.

Average Molecular Weights. The relative[27] molecular weights of the various fractions of low- and high-temperature bases were determined by the ordinary Beckmann cryoscopic method, using benzene as the solvent. It was found that as the boiling points of the fractions increase the difference between the respective molecular weights varies in much the same fashion as the difference in specific gravity (Fig. 8), the maximum variation being 15 to 20 in the middle-boiling fractions. Hence the lower densities of the Carbocoal bases seem chiefly ascribable to the presence of aliphatic side-chains of molecular weight higher than those of the higher-temperature bases. This conclusion gains weight from a consideration of the analogous relationships between the principal hydrocarbons of low- and high-temperature tars discussed below.

Previous Investigations. Jones and Wheeler[2] were unable to obtain more than traces of nitrogen bases in the small amount of tar at their disposal. Parr[3] reported an average of 0.23 per cent of "amines" on the basis of the crude, dry tar in the fractions boiling below 260 deg. C. Gluud[26] announced 0.46 per cent of "pyridine" in the Lohberg coal tar mentioned above (Table II). These investigators did not interest themselves in the nature of the bases.

Pictet[1] found 0.2 per cent of bases in the "vacuum tar" of Montrambert coal. He reported primary amines to be present, and identified the fraction 198-203 deg. as a mixture of toluidines. Pyridine and other tertiary amines appeared to be absent. Ultimate analysis of the picrates of the higher fractions showed them to be the dihydro-derivatives of quinoline and iso-quinoline. The significance of the absence of tertiary bases in this tar and their presence in low-temperature tar is discussed in the section on secondary carbonization reactions.

Alcohol and Sulphur Compounds

Alcohols. A sample of the low-temperature distillate freed of tar-acids and bases was boiled with metallic sodium, but no evolution of hydrogen or loss in weight of sodium was observed. Alcohols are therefore absent. Pictet[2] found 2 per cent of alcohols in "vacuum tar." The lowest-boiling component proved to be hexahydro-*p*-cresol; the others were isomers of monatomic phenols, a mixture of which they yielded on simple standing for a month. No other investigator has reported alcohols in low-temperature coal tars.

Sulphur Compounds. Hydrogen sulphide was determined (0.08-0.1 per cent) in the first two fractions of the low-temperature distillate, but most of this compound is to be found in the gaseous and aqueous products of distillation. A negative phenylhydrazine test showed the absence of carbon disulphide. Thiophene is indeterminate by the indophenine, thallin and mercuric salt tests in the presence of the large proportion of unsaturated hydrocarbons, which cannot be removed alone. No analyses of sulphur compounds are reported in the literature.

The Saturated Hydrocarbons

Examination of the Hydrocarbon Mixture. The neutral oils remaining after the extraction of the tar-acids and bases constitute the hydrocarbons of low-temperature tar. When freshly distilled, the lower fractions are pale yellow and the higher fractions amber colored. After standing for several weeks, all of the fractions become quite black in color, and deposit on the walls and bottoms of the bottles a thin, black coating. This is evidently due to the spontaneous polymerization or oxidation of a very small portion of the unsaturated compounds present, and is more marked in the lower than in the higher fractions. The density of fraction 20-173 deg. increased 0.012 on standing for 4 months.

The specific gravity of the total mixed hydrocarbons in the fresh distillate was found to be 0.891 at 25 deg./4 deg. as opposed to 1.028 of the coke-oven hydrocarbons distilled under similar conditions. Fractional distillation of the Carbocoal hydrocarbons shows the presence of no preponderant single compound such as the naphthalene of high-temperature tar. Since only a few very fine flakes of white crystals could be obtained in fractions cooled to —30 deg. C., only traces of solid aromatic hydrocarbons, such as naphthalene

[27] Pyridine bases are slightly associated in benzene solution.

or anthracene, can be present in the low-temperature tar.

Composition of the Mixture: Separation of the Classes of Compounds. All fractions of the hydrocarbons from low-temperature tar instantly reduced a 1 per cent aqueous solution of potassium permanganate, and rapidly decolorized a solution of bromine in chloroform. Unsaturated hydrocarbons were therefore present in considerable quantity. Means for the qualitative detection of the other classes of components are lacking, however. Previous investigators have reported in low-temperature tars the following groups of hydrocarbons, listed in the order of their chemical activity:

1. Unsaturated (olefinic and cyclic).
2. Aromatic (liquid).
3. Naphthene (saturated cyclic).
4. Paraffine (liquid and solid).

Determination of the Percentage of Paraffine Plus Naphthene Hydrocarbons in the Neutral Residues. This analysis was accomplished by the treatment of 15 to 20 g. samples with 75 c.c. of 98 per cent sulphuric acid.[28] Each sample was agitated for half an hour in a glass-stoppered separatory funnel, and the weight of the residual oils determined. The results were corrected for polymerization[29] of the unsaturated hydrocarbons by a method based on redistillation of the residual saturated oils and subtraction of a quantity equivalent to the weight of the dissolved polymers. All determinations were made in duplicate, and the means of the closely agreeing values are plotted in Fig. 2. The percentage of saturated hydrocarbons thus obtained (13.9 per cent) is much lower than any previ-

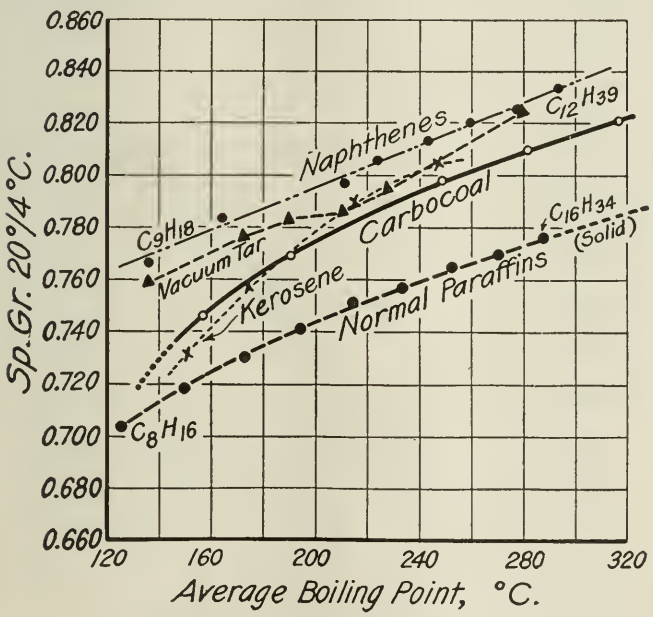

FIG. 9—SP.GR. OF SATURATED HYDROCARBONS

ously reported (Table II). This is explained in the section on secondary carbonization reactions.

Estimation of the Naphthenes. The indices of refraction and specific gravities of the redistilled saturated hydrocarbons were determined. Fig. 9 shows that the graphical relation between the densities and boiling points of these residual oils offers a method of approximating the proportions of paraffines and naphthenes. The densities plotted for the naphthenes are those reported[30] for hydrocarbons of formula C_nH_{2n} isolated from crude petroleum. It is apparent that the position of the Carbocoal curve between the naphthene and paraffine curves may be used as a basis of estimating the proportions of these groups of hydrocarbons. No great accuracy can be claimed for such an approximation, since the densities of the naphthenes vary slightly according to the nature of the hydrocarbon, although they are much less erratic than the corresponding indices of refraction. Representative values were selected, however, and it is believed that a fair picture may thus be obtained of the composition of the saturated hydrocarbons from low-temperature tar. The distillate thus contained 8.8 per cent naphthenes and 5.1 per cent paraffines.

An interesting sidelight on the nature of these hydrocarbons from low-temperature tars is given by a comparative examination of oils of the same boiling point from crude petroleum. A kerosene from the mid-continental field was washed thoroughly a number of times with oleum until no test was given for unsaturation. The water-white oil thus obtained after washing with alkali and redistilling possessed the same fragrant odor as the saturated hydrocarbons. The refractive indices and specific gravities (*cf.* Fig. 9) of the fractions of this refined kerosene reveal a striking similarity between these two groups of oils, one obtained from coal and the other from petroleum.

Previous Investigations. Previous investigators have interested themselves primarily in the qualitative study of individual compounds. Fischer and Gluud[31] cooled a dilute acetone solution of the oils to about —70 deg. C. with liquid air. They estimated that the "benzine" fraction (below 200 deg.), the "illuminating oil" fraction (200-300 deg.), and the "lubricating oil" fraction (above 300 deg.) each contained 10 per cent of paraffines. The paraffines boiling between 200 deg. and 300 deg. were liquid ($C_{10}H_{22}$ to $C_{19}H_{40}$) and those in the higher fractions were solid ($C_{24}H_{50}$ to $C_{29}H_{60}$).

Ultimate analysis has been employed by other investigators for the same purpose. Jones and Wheeler[2] reported a mixture of naphthenes with a small quantity of paraffines in the saturated fraction 35-125 deg. C. of their low-temperature tar, but concluded from the high percentages of carbon in the fractions boiling between 150 and 300 deg. that they "must consist of naphthenes only, or, what is less likely, of mixtures of paraffines with hydrocarbons richer in carbon than the polymethylenes." Solid paraffines ($C_{26}H_{54}$ and $C_{27}H_{56}$) were crystallized from the fraction 200-260 deg. at 30 mm.

Pictet[1] examined the six fractions of "vacuum tar" obtained between 135 and 285 deg. after extraction with liquid sulphur dioxide, and reported all to have the general formula of the naphthenes. He was able to identify the hexahydro-derivatives of mesitylene and durene. The only solid hydrocarbon found was a naphthene, melene ($C_{30}H_{60}$).

The Non-Saturated Hydrocarbons

The unsaturated and aromatic hydrocarbons constitute the second largest group in the low-temperature tar. The distillate contains 41.5 per cent of these compounds, while the tar-acids amount to 42.7 per cent.

The low density and congealing point of the total hydrocarbon mixture point to the absence of ordinary solid aromatic hydrocarbons and to the preponderance of the unsaturated components. The specific gravities at 20 deg./4 deg. of the non-saturated fractions were calculated, as shown in Fig. 10, from the densities of the total neutral oils and of the saturated hydrocarbons, and from the known percentages of saturated hydrocarbons in the neutral oils. The curve thus obtained is too high for the densities of the olefines, and indi-

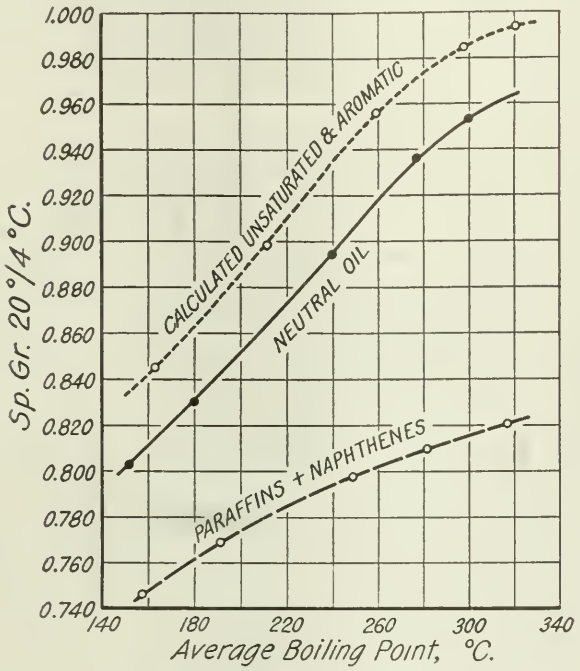

FIG. 10—SPECIFIC GRAVITIES OF HYDROCARBONS FROM LOW-TEMPERATURE TAR

cates that the unsaturated hydrocarbons are cyclic in character.

Recovery of the Non-Saturated Hydrocarbons. The only method that appears to offer a means of recovering the non-saturated (unsaturated and aromatic) hydrocarbons comparatively free from naphthenes and paraffines is extraction with liquid sulphur dioxide. Although the fraction 20-173 deg. is miscible with this solvent[32] in all proportions at —35 deg. C., the separations accomplished are sharper and more specific in hydrocarbon mixtures of high molecular weight. While non-saturated hydrocarbons can be recovered in this manner, doubt must be cast on their purity, therefore, because of the variation in the effect of the solvent throughout the wide range of compounds involved. In particular it is to be expected that the lower fractions will be found admixed with a portion of the naphthene and paraffine hydrocarbons.

Using a ratio of three parts by volume of oil to five parts of liquid sulphur dioxide and the apparatus and method described by Bowrey,[33] a hydrocarbon mixture constituting a representative sample of the combined fractions was resolved into two parts; an extract containing the non-saturated and a small quantity of low-boiling saturated hydrocarbons, and a residue composed principally of saturated hydrocarbons.

Examination of the Non-Saturated Hydrocarbons. The oils recovered from the sulphur dioxide layer were washed with alkali and subjected to three very slow fractionations with a Vigreux head. The distillates were water-white at first, but after exposure to the atmosphere for only a few minutes became amber colored; the higher fractions showed a violet fluorescence. All fractions could be distilled at atmospheric pressure with only slight decomposition. The specific gravities and indices of refraction of the seventeen fractions collected were determined. Fig. 11 shows these specific gravities, both observed and calculated, plotted against the average boiling points of the respective fractions.

It was expected that admixture with saturated hydrocarbons would cause the observed values in the lowest-boiling fractions to fall below those calculated. The calculated curve is too incomplete to establish this point, but the "vacuum tar" data also plotted in the figure show the same effect. Although it is very probable that low-boiling saturated hydrocarbons were present in this extract, the large number of fractionations to which they were subjected would be effective in eliminating most of them from the restricted fractions selected for analysis as chemical individuals.

The striking resemblance between the non-saturated hydrocarbons from low-temperature tar and "vacuum tar" extends to the respective refractive indices and average molecular weights, which were determined in selected fractions by the usual Beckmann cryoscopic method. The close agreement between the physical constants of these hydrocarbons shows that the non-saturated compounds from the former apparently belong in general to the same class of cyclic, unsaturated hydrocarbons described by Pictet.[1] In this series he

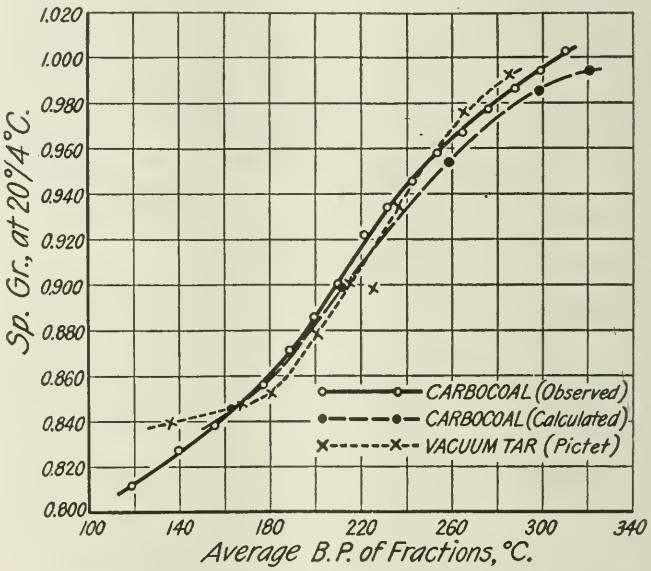

FIG. 11—SPECIFIC GRAVITIES OF NON-SATURATED HYDROCARBONS

was able to identify dihydro-*m*-xylene, dihydromesitylene, dihydroprehnitene and hexahydrofluorene. The higher-boiling members of the series have from three to five double bonds (basis of molecular refraction), and are apparently polycyclic. No aromatic hydrocarbons were detected.

Aromatic Hydrocarbons in the Non-Saturated Oils. The very low congealing temperatures of all of the fractions demonstrate the absence of solid aromatic hydrocarbons of the type occurring in ordinary high-

temperature coal tar. Evidence also is not lacking to indicate that no considerable percentage of liquid aromatic hydrocarbons can be present. The densities and indices of refraction of the non-saturated hydrocarbons are notably lower than the corresponding constants of aromatic hydrocarbons of the same boiling point. Moreover, close conformity has been demonstrated between the physical properties of the non-saturated hydrocarbons of Carbocoal tar and a series of unsaturated, cyclic compounds among which no aromatics were detected.

Summary

(1) A commercial low-temperature tar has been compared with coke-oven and gas-works tars. The density and "free carbon" content of the crude, dry tars and the density, "free carbon" and air melting point of the pitches remaining after fractional distillation under similar conditions have been determined. The values for the low-temperature tar have been shown to be notably lower than the corresponding figures obtained for the coke-oven and gas-works tars. The fractionation curves of the three tars, however, are very similar.

(2) The phenols have been extracted from each fraction and estimated gravimetrically. The percentages of phenol and the cresols have been found by methods involving nitration and the determination of specific gravities and freezing points. Derivatives of the naphthols are present, but α- and β-naphthol are absent.

(3) The percentage of phenols in low-temperature tars increases with the yield of tar from the coal carbonized, the quantity of non-phenolic oil remaining relatively constant. In general, coals of the highest volatile content yield the most phenols.

(4) The nitrogen bases are 80 per cent tertiary, 20 per cent secondary, and contain no primary compounds. Both types show unsaturation. No preponderant compound is present. Pyridine has been detected in the first fraction, but the higher boiling bases differ from those in ordinary coal tar in that they have lower densities and higher molecular weights. These differences are ascribed to the presence in the low-temperature bases of partly hydrogenated nuclei and of side-chains longer than those characterizing high-temperature bases.

(5) Contrary to the "vacuum tar" of Pictet, low-temperature tar contains no alcohols.

(6) Hydrogen sulphide is present in the lowest fractions, but carbon disulphide is absent. Thiophene is indeterminate in the presence of unsaturated hydrocarbons, which can not be removed.

(7) The neutral oils derived from low-temperature tars are characterized by low density and viscosity, and by the absence of more than traces of compounds solid above —30 deg. C. No single hydrocarbon preponderates in quantity. Unsaturated hydrocarbons are present, and on standing cause darkening and gradual increase in density of the oils. By the use of 98 per cent sulphuric acid, the saturated and non-saturated hydrocarbons have been separated. Correction is made for polymerization. The proportion of napthenes has been determined from the specific gravities of the residual saturated hydrocarbons.

(8) The non-saturated hydrocarbons recovered by liquid sulphur dioxide have been shown by determinations of density, index of refraction and molecular weight to belong to the same series of cyclic unsaturated hydrocarbons as those occurring in "vacuum tar." Solid aromatic hydrocarbons are absent; liquid aromatic hydrocarbons can be present only in traces.

A Study of the Effect of Impurities on Storage Batteries*

By Helen C. Gillette
Research Laboratory, Prest-O-Lite Co., Inc.

THE increasing use of storage batteries for starting and lighting of automobiles augments the importance of knowing more of both the theoretical and practical functioning of the cell. Among other factors, the necessary purity of materials to insure capacity is of prime importance to the manufacturer. Also, since the introduction of foreign materials in the adjustment of electrolyte during the service of the cell is not an impossibility, the magnitude of the effect of this introduction has been a source of annoying doubt, even though experience abetted by theory has compiled a generous number of proverbs as to the harmful effect of traces of "impurities."

The literature contains frequent references to the injurious effect of foreign materials, but specific data are lacking. The acids nitric, hydrochloric and acetic attack the structure of the plate, but the concentrations at which these acids are harmful have not, to the writer's knowledge, been previously published. Of the metals, the most concrete reference is in "Accumulators," by Dolzalek, in which it is stated that those metals existing in more than one valence and which are above lead in the electromotive series cause an abnormal loss of capacity on standing. Those metals which are below lead plate out on the negative electrode, resulting in local action and the rapid discharge of that plate. Vicarey[1] has done considerable work on the detrimental effects of ammonia, and advises the manufacture of storage batteries at points as far distant from human habitation as possible, to eliminate this deleterious gas. With the present-day experience in the frequent use of ammonium salts in plate manufacture, the conclusions of Vicarey are but of amusing historical interest.

Standardization of Cells

In interpreting data upon storage cells it must be remembered that lead cells cling tenaciously to individual rights of performance. This is especially true with reference to capacity and rate of self-discharge. Therefore, in order to distinguish the effect of the added impurity with greater certainty from the idiosyncrasies of the individual cells, the latter were put through preliminary cycles of charge and discharge until the ampere-hour output had attained a constant and characteristic value. This established the history of the cells prior to their employment in the test and prevented the use of abnormal cells. The standardization of each

*A portion of data incorporated in thesis for M.S. degree at Purdue University in a paper read and presented at the forty-first general meeting of the American Electrochemical Society at Baltimore, April 27-29, 1922.

[1] *Trans.*, Faraday Society, 1905, vol. 1, p. 271; 1906, vol. 2, p. 222.

test cell was the more important because it was impracticable to allot more than two cells to each combination owing to the number of combinations studied. In spite of the limited number of cells, the observations are therefore considered substantially indicative, but are not presented as quantitatively final in every case.

Contaminating Agents

In each series two uncontaminated cells were included, making eighteen cells in all, from which the average capacity and life of the entire group of batteries could be very reliably determined. The metallic impurities used were antimony, arsenic, cadmium, iron, magnesium, manganese, mercury, nickel, platinum, tin, silver and zinc. These were introduced as solutions of their salts. The contaminating acids employed were acetic, hydrochloric and nitric. The impurities were in all cases added in definite percentages of the electrolyte by weight.

The characteristics of storage battery performance which might be adversely affected are classified under four headings:

1. The ampere-hour capacity or output of the battery on discharge.
2. The voltage characteristics on charge and discharge.
3. The rate of self-discharge of the charged battery upon standing.
4. The life of the active material, which is conditioned mainly by the rate of mechanical disintegration in successive cycles.

Experimentally, the changes in these characteristics were determined by measurements of (1) the ampere-hour capacity on discharge immediately following charge; (2) voltage characteristics on charge and discharge; (3) loss of capacity on standing for definite time intervals after charge; and (4) the relative life compared with uncontaminated cells.

Experimental Observations

The effect of the impurities on the ampere-hour output of the charged battery was surprising. It had been expected that the impurities, especially those metals readily capable of oxidation, would produce considerable change in the capacity of the cells. However, contrary to this expectation, the tests showed that the discharge capacity was unaffected except in three cases—namely, silver, manganese and platinum—which will be considered in more detail later.

Likewise, observations of the voltage characteristics showed them to be unexpectedly impervious to attacks of impurities. The addition of antimony lowered the charge voltage for a few cycles, after which, however, the cell regained its normal voltage performance. The antimony was probably deposited and plated over on the negative plate. The other impurities, except silver and platinum, were without perceptible influence upon the voltage characteristics.

When, however, we come to the consideration of the self-discharge of the battery and the life of the active material a much more varied behavior becomes apparent, as will be observed in Table I.

The self-discharge or loss of capacity on standing was determined by allowing the cells to stand after charging for intervals of 1 day, 1 week and 4 weeks, respectively, before discharge. They were then discharged at the 5-hour rate. Since the same relative loss in capacity was observed for each of the periods, the loss in capacity for the 4-week period only has been recorded. In the third column of the table this loss is expressed as a percentage of the previously determined capacity of the cell.

TABLE I—EFFECT OF IMPURITIES ON SELF-DISCHARGE AND LIFE OF CELLS

Impurity Per Cent of Electrolyte, Weights	Compound in Which Introduced	Per Cent of Former Capacity After Standing 4 Weeks	Life Tests Performance of Uncontaminated Cells Considered 100 Per Cent
Magnesium....0.05	$MgSO_4.7H_2O$	92.5	85.7

Compounds were added in some instances in 39 per cent sulphuric acid solution to prevent altering the specific gravity of electrolyte. All metallic impurities were added one-half hour before completion of charge. Foreign acids were added with original electrolyte on assembly of cells.

(1) Other cells too low to put in life test.
(2) After standing one week.
(3) Loss to these figures in six cycles.
(4) Torn down after standing test. No grid disintegration yet apparent.
(5) Not tested.
(6) Immediate complete sulfation..

The life test consisted of consecutive charges and discharges until the capacity fell to a definite fraction of its former value. Rating the performance of the uncontaminated cells at 100 per cent, the relative performance of the contaminated cells is tabulated in column 4.

In order to interpret the results of Table I in terms of practical injury to the battery, certain arbitrary assumptions must be made.

First, with respect to self-discharge, a normal or average depreciation of about 18 per cent was observed in the uncontaminated cells after standing 4 weeks.

Therefore, we have rated at 100 cells which retained at least 82 per cent of their original capacity. Moreover, since normal cells are subject to some variation, we have assumed that no deviation of less than 10 points from the normal thus established can be considered significant.

In like manner, the life of the uncontaminated plates under the experimental conditions was rated at 100, and only a depreciation in excess of 15 per cent of this average has been considered significant. The greater margin required for establishing significant differences in the case of the life tests is due to the greater variability of the latter owing to the large number of factors which influence it. The allowances in each case are sufficient to exclude the maximum variations observed in the control cells.

With these assumptions as to what constitutes practical injury, Table II has been prepared. In the first two columns are indicated the minimum amount of the impurity which proved definitely injurious. In the last two columns are given the maximum percentages of the impurity which produced no pronounced deterioration in the cell.

TABLE II—MAXIMUM AND MINIMUM LIMITS FOR IMPURITIES IN STORAGE BATTERIES

	Minimum Percentage Which Produced Injury		Maximum Percentage Which Produced No Injury	
	Self-Discharge	Life	Self-Discharge	Life
Magnesium	....	0.5	0.5	0.05
Manganese	0.005	0.005	....	....
Zinc	....	....	0.5	0.5
Cadmium	....	0.5	0.5	0.05
Iron	....	0.1	0.1	0.05
Nickel	....	....	0.5	0.5
Tin	....	....	0.5	0.5

Antimony	0.5	0.5	0.05	0.05
Mercury	....	0.5	0.5	0.05
Silver	0.1	....	0.05	0.5
Platinum	Not tested	0.00001	....	....
Hydrochloric acid	Not tested	1.0	Not tested	0.5
Nitric acid	5	....	1.0	1.0
Acetic acid	Not tested	5.0	Not tested	1.0

The cells with 0.5 cadmium showed abnormally short life, although the 0.05 cadmium were normal. This is of special interest in connection with the common use of the cadmium electrode in lead battery testing. Further verification is therefore desirable. The effect of the introduction of antimony was also somewhat surprising, but the result may have been due in part to the hydrochloric acid solution in which it was introduced.

Special Effects Caused by Mn, Ag and Pt

The cases of manganese, silver and platinum presented striking characteristics.

Manganese as potassium permanganate in water solution was added in quantities of 0.05 and 0.5 per cent of the electrolyte weight. There was a steady lessening of capacity with successive discharges immediately following charge until in twenty cycles after the addition of the manganese the cells had fallen to 83 and 52 per cent of their original values for the 0.05 per cent and 0.5 per cent additions, respectively. After a week's standing, the capacity had fallen so low that the cells were torn down and a new series of tests started to confirm the result. Potassium permanganate was then added to correspond to 0.005, 0.01, 0.025 and 0.05 per cent of manganese in the electrolyte. All showed an abnormal loss of capacity on standing, and after 4 weeks those contaminated with 0.025 and 0.05 per cent refused to "take charge." The two lower percentages gave short life. The positive plates when examined were expanded, pitted and buckled and the general character of the paste was soft. The negatives were normal.

The addition of silver in water solution of silver nitrate resulted in the immediate precipitation of silver sulphate, shorting the cells and reducing the capacity to 18 per cent normal with the 0.5 per cent contamination. This capacity was regained with succeeding cycles and in six equalled its former value. A repetition of the test in which the silver nitrite solution was previously digested with sulphuric acid gave a less marked, although noticeable, decrease in initial capacity, which was regained as in the former series. It seems probable that the silver was plated over with spongy lead and rendered less harmful on the negative electrode. However, its effect is seen in the loss of capacity on standing.

Platinum gave no room for doubt as to its result. Added even as low as 0.00001 per cent, it caused immediate gassing on discharge, and in five cycles of successive charge and discharge the capacity had fallen to 50 per cent. On examination, the negatives exhibited a soft, pasty character. The cell voltage on charge failed to rise above 2.37 with a positive to cadmium of 2.42 volts, while the normal cell gives 2.60 as a cell voltage and 2.45 of the positive with respect to cadmium.

Methods of Detection

Detection of these impurities by other than chemical analysis of the electrolyte is possible only in the cases of manganese, platinum, hydrochloric and acetic acids. Manganese gives the characteristic permanganate color on charge, and the pitted condition of the positive is also an indication. Platinum is distinguished with certainty by gassing of the cell on discharge. Hydrochloric and acetic acids as well as nitric attack the positive grid, but the first two may usually be detected by the odor on charge. Chlorine is evolved from the hydrochloric acid and the characteristic odor of acetic is attendant on that impurity. However, these are not absolute criteria, for successive cycles of electrolysis decrease the concentration almost to elimination. Hydrochloric bleaches a wood separator, while with acetic acid there is an unusual growth of lead sulphate crystals around the cell posts.

Recent Work on Non-Ferrous Alloys

At a recent conference of the advisory committee on non-ferrous alloys of the Institute of Metals Division of the A.I.M.E., R. J. Anderson, metallurgist of the Bureau of Mines, outlined the results of recent work at the Pittsburgh experiment station in regard to (1) the contraction of aluminum alloys, (2) removal of stress in brass tubing and (3) heat-treatment of cast non-ferrous alloys. He stated that linear contraction experiments had been run in chill molds and sand molds on forty aluminum alloys, and the results showed that in the series of alloys the contraction varied between the limits 0.95 and 1.70 per cent. In the general discussion of the contraction and shrinkage problem, it was felt that the whole situation needed clarifying and that the results of the work should be made available. It was stated that shrinkage is dependent upon structural changes occurring on solidification and that there is not necessarily any relation among shrinkage, hot-shortness and tensile strength. It was stated also that the effect of degasifying and deoxidizing alloys might have considerable effect on shrinkage and hot-shortness. The investigation of the effect of chills, risers and molding practice upon shrinkage was suggested.

Physical Metallurgy at Columbia University

All Engineering Students Are Required to Attend a Course in Metallurgy—Many Chemists Elect the Long Course for Metallurgists—Instruction Continues Through the Summer School for Special Students—Excellent Equipment in Laboratory for Preparation and Examination of Samples

By ERNEST E. THUM

WORK in metallurgy has always been a very important part of that assigned to students at Columbia School of Mines ever since its foundation, in 1864. It would be interesting to trace the variations in the curriculum as they have occurred in the intervening years; such a statement would roughly parallel the history of the metallurgical industries in the United States. However, that is not the present purpose, but rather to describe the equipment now available at Columbia University for the study of metallography.

Although metallography is doubtless a junior branch of the wider science, it may be interesting to know that it has been taught at Columbia for over 20 years by Prof. William Campbell, and to a continually widening circle of engineers. Starting as an advanced study for metallurgical specialists, a brief course is now taught to all men attending the engineering college, while chemical engineers take a continuation course as an adjunct to their work in physical chemistry and phase rule. The mechanical and industrial engineers take the laboratory course and metallurgists also naturally spend extra time on this subject. Interested students can go as far forward as they like.

Courses of Study in Metallography

Several different courses are offered. As mentioned above, all engineering students are required to attend thirty lecture periods of a course on metallurgy of iron and steel. About half the lectures are devoted to a consideration of iron smelting and steel making, while the remainder are devoted to the properties of engineering steels and a few industrial alloys and how they are affected by composition, working and heat-treatment. Of course, it is readily understood that in such a limited time the treatment cannot be exhaustive in any detail. The student, however, is provided with an extended outline, nearly every item of which has one or more references to the literature. In this way he is given a perspective of the subject and a ready means to acquire detailed information on any branch he may later become interested in. Bradley Stoughton's "Metallurgy of Iron and Steel" (McGraw-Hill) and G. H. Gulliver's "Metallic Alloys" (Charles Griffin & Co.) are the textbooks.

In addition to the lectures, the engineering students spend fourteen laboratory afternoons on the subject, mostly engaged in the microscopic examination of a series of prepared samples, typical of alloys used in engineering construction. The equipment, to be described later, is arranged so that each student sketches the structure of each sample in his notebook, records the physical properties of that kind of material and makes explanatory remarks and comments on the notable features called to his attention by a syllabus. A number of useful textbooks are kept in the laboratory and are in constant use clearing up obscurities.

Extended Courses for Chemists and Metallurgists

In addition to the course in metallurgy of iron and steel, chemical and metallurgical engineers are required to continue with another series of lectures on metallography. Many chemists working for A.B. and Ph.D. degrees also elect the course as an adjunct to their work in physical chemistry and phase rule, and evince a surprising interest in the work. This course also follows an exhaustive outline and bibliography of the subject placed in the hands of each student, wherein binary alloys are classified according to chemical compounds which may or may not be formed, whether the mutual solubility in the liquid is complete, partial or lacking, and according to the conditions of solid solubility. In other words, Roozeboom's classification is used, and the actual equilibrium diagrams of the useful alloys are analyzed into their elements. So much stress is laid upon the fact that a thermal diagram is a map of actual occurrences that finally the student believes it and is able to use such diagrams intelligently.

Laboratory work in metallography parallels the lectures. One hundred prepared type specimens are examined, sketched in notebooks and discussed. While the condition of the samples as received by the student is in general very good, several of them must be lightly repolished and etched, giving the students skill in this delicate operation. (One or two samples are prepared from the rough as well.) No formal instruction in photography is given. If the student is interested enough, and many of them are, the method is illustrated to him, and he proceeds to make a few exposures and develop the plates. He is impressed with the fact that it requires skill to make a good photograph, but that it is perfectly possible to acquire that skill as it is needed. A good photographer can be a very poor metallographist—and vice versa (but the chances are the latter will not remain so).

For many years a rather extended series of furnace experiments were conducted, following Prof. Henry M. Howe's laboratory notebook. It became apparent, however, that the results achieved were not as good as could be had by the same expenditure of time and energy in a different channel. Consequently at the present time the regular class instruction is confined to three furnace experiments on steel; first the "Metcalf" test (where a bar, overheated at one end and cold at the other, is broken in pieces and the various fractures noted); Brinell's series of heat-treatments (where the fracture of tool steel is examined after various quenchings, temperings and annealings) and the making, hardening and tempering of a cold chisel. Of course, equipment for

precise heat-treatment is available for students of ability who are able to spend the necessary time on quasi-research work.

The above-described longer course is also repeated in the summer school, when it is compressed into 6 weeks of practically continuous work immediately following July 4. Students registering for summer school and who in fact may not be able to pass all the entrance requirements for the Engineering College or School of Mines—schools which are really for post-graduate instruction—may thus get the complete instruction in metallography in a very short time and for a very small fee. Elementary physics and chemistry, such as taught in high school, are prerequisite for this work; registration may otherwise be made by any student who feels that he can profit by the study.

Metallographical Laboratory

After completion of the present School of Mines Building (donated by Adolph Lewisohn in 1904) the metallographical laboratory was installed in the north wing of the sixth floor, a large room, well lighted by broad windows on three sides and a skylight. Fig. 1 shows a floor plan. One half of the area is devoted to the preparation of samples, while the other half is reserved for microscopic examination.

Samples are cut out of larger specimens in a machine shop, located next door, a shop which contains a shaper, lathe, drill press, saw, emery disk wheel and anvil, in addition to convenient workbenches and tool cabinets.

Finish grinding is done on a series of grinding wheels against the north wall of the main laboratory. These are of a very substantial design for double 8-in. wheels, made by the Norton Co., belt driven from a line shaft above. Tough alloys, especially non-ferrous alloys, are

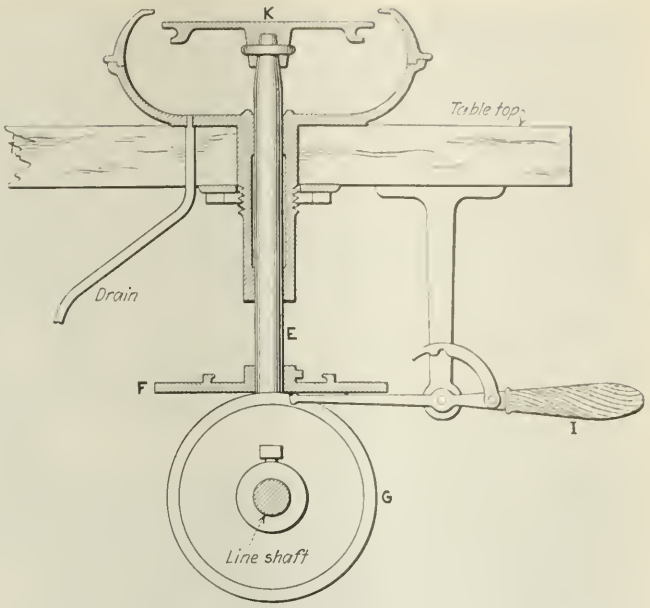

FIG. 2—DIAGRAM OF ZIMMERSHIED POLISHING WHEEL

more readily flattened by "smooth" and "dead smooth" files. Five small swivel vises are provided along the west wall for this purpose—to hold the files, not the specimens. Final polishing is done on polishing disks, a series of which are provided in a machine designed and furnished by Prof. Zimmershied, then of University of Michigan, Ann Arbor. This excellent device is described in detail in the *Journal of the American Chemical Society*, vol. 29, p. 856, and consists of two rotating longitudinal shafts, motor driven, under a long table top. Polishing wheels *K* have a vertical axis of rota-

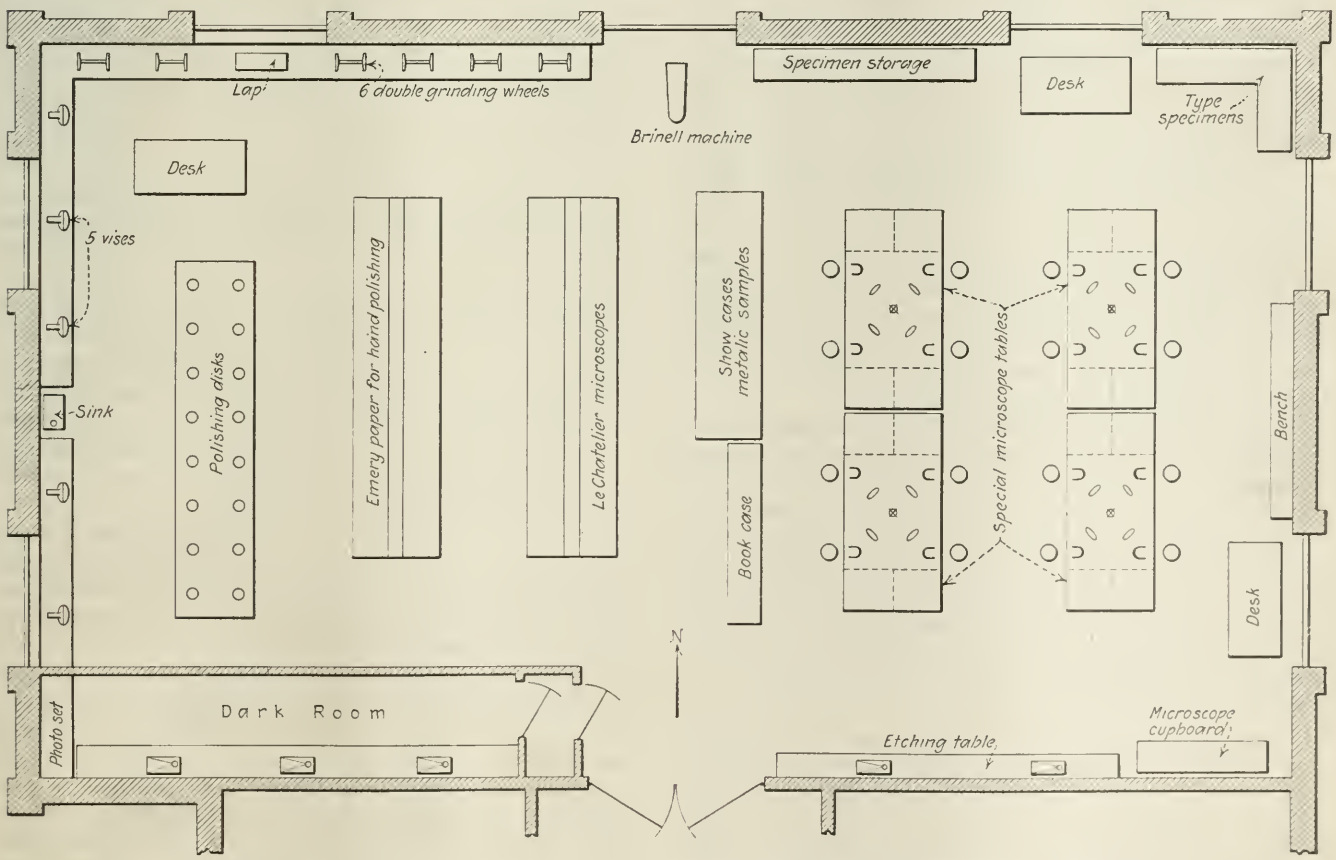

FIG. 1—FLOOR PLAN OF METALLOGRAPHY LABORATORY, COLUMBIA UNIVERSITY

FIG. 3—MICROSCOPE EQUIPMENT FOR STUDENT USE, COLUMBIA UNIVERSITY

tion (*E*, Fig. 2); they are driven by friction disks *G* and *F*, and when not in use are raised up clear by a lever *I*. About 18 in. above the working table has been fixed a series of small cabinets, containing spare disks and bottled abrasives.

Extremely brittle material, especially mattes, will not stand the emery wheel and is taken down on a lap, or by rubbing on a flat glass plate charged with FFF carborundum powder. Alongside the Zimmershied machine is a pair of stone-topped tables from the old chemical laboratory. These are kept clear for sheets of emery paper for use when polishing specimens by hand.

Experience with this layout indicates that it could be improved by locating the rough-grinding machinery near together, and inclosing them in a tight partition. This would prevent coarser particles of grit being blown on the cloth disks. These in turn should be covered with a hinged hood when not in use.

A second table from the old chemical laboratory is utilized for a series of LeChatelier microscopes when necessary to handle an overflow of students, but ordinarily there is enough room at the four special microscope tables at the east end of the room, illustrated in Fig. 3. These are 4 ft. x 8 ft. in area, with a flat top set 29 in. from the floor. Under each end can be seen a small cupboard, and three flat drawers (2 in. deep x 1 ft. 9 in. square). Four students work at each table simultaneously, sitting on stools placed as indicated in the plan, Fig. 1.

Each microscope on these tables has been simplified to its bare essentials. Leitz instruments with fixed stages are used; an objective with a plane glass reflector is attached to the lower end of the tube. Magnifications of from 150 to 175 diameters are available by choice of different eyepieces. Fine details of structure may be studied at magnifications of 500 diameters or more, on a high-power microscope at an instructor's desk. There are three such instruments.

In order that up-and-down movement of the objective may be confined to small adjustments on the slow motion screw, it is essential that the specimen be always mounted a fixed distance above the stage. This is done in a simple manner, as indicated in Fig. 4. A spun brass cup, about 2¼ in. diameter and 1 in. deep, with upper edge milled parallel to the base, contains a lump of plasticene, into which the specimen is pressed by a square of plate glass. Plasticene is better than shot, since it cannot be spilled. The cup rim is also very useful to prevent dislodging the specimen by an accidental touch.

In such a layout as shown in Figs. 1 and 3, four microscopes are very conveniently illuminated by a single Welsbach mantle; the lamp is heavily shaded above to prevent glare. A simple condensing lens projects a beam into the reflector.

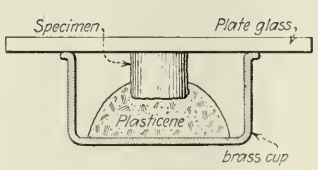

FIG. 4—MOUNTING CUP

Etching is done at a long table made of chemically resistant stone set against the wall. Convenient reagent shelves, sinks, water and gas lines are installed here, as is shown clearly in Fig. 3.

A dark room has been partitioned off for student use. It is somewhat too narrow for comfort. A micrographic set is placed on a bench at one end, and along the wall are three complete sets of light-tight cupboards, developing tanks, sinks and printing frames. Entrance is through a double door with pilot lights.

Specimens for study are stored in a cabinet in one corner. As noted above, each student is provided with

a partitioned tray (Fig. 3) containing a full set of the samples assigned for his particular course. Therefore there are several thousand specimens ready for use. In addition the laboratory possesses many thousand prepared and catalogued specimens of mattes, slags, ores and steels available for the special study of various metallurgical processes, such as steel making, carburizing, annealing and other thermal operations. Several glass exhibition cases contain large samples of defective materials. A very large number of metallic specimens of almost every commercial alloy are also available from accumulation during the past, only a part of which have been studied in detail.

The Production of Metallic Magnesium*

By S. T. Allen
Chief Engineer and General Manager,
Wolverhampton Electricity Department

THE IMPORTANCE of magnesium metal has greatly increased during the last few years, because of its present value and future possibilities in connection with the alloying of other non-ferrous metals, where extreme lightness and high strength are required, such as in the building of airships and airplanes, and also because of its properties as a deoxidizer of other metals.

Magnesium is 40 per cent lighter than aluminum, and when pure is no more susceptible to atmospheric corrosion than is aluminum. Thus, given production as cheap as aluminum, which the Magnesium Co. states is a possibility, and provided that there is a corresponding demand, the uses in the future of this beautiful metal will certainly multiply. Its production will therefore be watched with considerable interest.

The intention of this article is more especially to describe the new electrolytic process developed in Wolverhampton by the Magnesium Co., which is already creating a considerable amount of interest throughout the world.

Raw Materials

The only two compounds of magnesium which occur abundantly in nature are the carbonate and chloride; the choice of the raw material for the production of the metal is accordingly limited to one or other of these compounds. Magnesite, the carbonate, is found in varying states of purity in all parts of the world. There are no deposits of pure magnesite in the United Kingdom, but large quantities occur as dolomite, the double carbonate of magnesium and calcium, from which pure carbonate of magnesium can be separated by simple processes. Magnesium chloride occurs in nature as one of the constituents of the German salt deposits. The separation of potassium chloride from these deposits involves the production of huge quantities of magnesium chloride. Magnesium chloride also occurs in sea water, and is a product of its evaporation for the production of salt. Either of these two compounds can be used as raw material, the choice being influenced by the cost of freight and the means available to the manufacturer for the disposal of his byproducts.

Suggested Processes

The processes which have been proposed or used for the production of magnesium may be placed under three headings: (1) Thermal processes; (2) substitution processes; and (3) direct electrolytic processes. In the first the oxide of magnesium is reduced by carbon at a temperature well within the range of the electric furnace. The metal is produced as vapor, which may be condensed. This process has been tried on a considerable scale, but great difficulties were encountered in attempts to produce coherent metal from the finely divided material (magnesium powder) which resulted from the condensation.

In the second process magnesium has been produced experimentally by the reduction of magnesium oxide with aluminum. Unlike the well-known "thermit" reactions, the reaction between magnesium oxide and aluminum is endothermic, and heat must be supplied. In the second process magnesium chloride is also readily reduced by metallic sodium, and at first sight this might appear to be an economic method of manufacture. To obtain satisfactory yields the magnesium chloride must be anhydrous, and as anhydrous magnesium chloride can be electrolyzed for the direct production of magnesium, reduction with sodium can be economical only if the sodium electrolytic cell shows a higher current efficiency than the magnesium electrolytic cell.

The choice of the electrolyte for the production of the metal by direct electrolysis is for practical purposes limited to the chloride and the fluoride, although claims have been made for the electrolysis of magnesium oxide in a bath of fused magnesium fluoride following the lines of the ordinary aluminum process. Electrolysis of the fused sulphide has also been proposed, but it is safe to say that all the magnesium for the market is produced by electrolysis of the chloride in a state of fusion with or without the admixture of potassium and sodium chlorides.

Preparation of Anhydrous Magnesium Chloride

The Magnesium Co. is interested in two processes for the production of anhydrous magnesium chloride, in one of which the chloride is produced by the action of chlorine on magnesium oxide, and in the other water is removed from magnesium chloride crystals.

In the presence of carbon, chlorine reacts with magnesium oxide, producing magnesium chloride and carbon monoxide. With pure materials the temperature at which this reaction is complete is uncommercially high. Compounds of iron act as chlorine carriers or catalysts of this reaction, and enable it to proceed to completion at a reasonable temperature. During the war large quantities of anhydrous magnesium chloride were made by this process and subsequently reduced to the metal. The complete dehydration of magnesium chloride crystals is not a simple matter, and has been made the subject of a large number of patents.

The following is a brief description of the process employed by the Magnesium Co.:

The crystals of magnesium chloride, after passing through a hydro extractor to remove adhering water, are exposed for several hours to a current of dry air at a temperature of about 150 deg. C. Half the combined water is thus removed with a small decomposition of the magnesium chloride, the product having the composition: $MgCl_2$, 73.0 per cent; MgO, 4.0 per cent; and H_2O, 23.0 per cent.

The partly dried material is now exposed to a current of dry hydrochloric acid gas at a temperature of about 300 deg. C. The remainder of the water is removed,

*From the *Electrician*, Jan. 27, 1922, p. 92.

the magnesium oxide is converted into magnesium chloride, and a product showing over 99 per cent of magnesium chloride results. As the temperature of fusion is never reached during the drying process, the crystals retain their original form, and in consequence the product is very easy to handle. The hydrochloric acid gas used in the drying process is produced by direct combination of hydrogen and chlorine, resulting from the electrolysis of brine.

Electrolytic Arrangements

As the melting point of anhydrous magnesium chloride, 750 deg. C., is above the economical temperature for electrolysis, sodium or potassium chloride, or both, are added to the anhydrous magnesium chloride to produce the electrolyte. Molten magnesium floats on the surface of this electrolyte, and consequently a simple cell of the form used in the manufacture of aluminum cannot be employed. Such a cell would have to be fitted with permeable diaphragms in order to keep the chlorine out of contact with the magnesium. These diaphragms are a constant source of trouble and expense, and, further, they tend to reduce the energy efficiency of the cell. This difficulty has been got over by the Magnesium Co. by conducting the electrolysis in two stages.

Stage 1.—The cell, which is of cast steel lined with firebrick, is fitted with a gas-tight cast-iron cover which carries the graphite anodes. These have suitable openings for the discharge of the chlorine gas and the removal of the electrolyte. The cell is charged to the depth of a few inches with molten lead, which forms the cathode. On the surface of the lead cathode floats a 1-in. layer of the electrolyte, into which dip the ends of the graphite anodes. The gap between anodes and cathode surface is about $\frac{3}{4}$ in.

Circulation of Electrolyte

Means are provided for the circulation both of the electrolyte and the liquid lead cathode. The cell has a capacity of 5,000 amp., at a cathode current density of about 1,500 amp. per sq.ft., and a terminal voltage drop of about 5 volts. Under these conditions the cell is self-heating, and produces about 100 lb. of Mg per 24 hours in the form of an alloy with lead, with an ampere efficiency of approximately 85 per cent.

Stage 2.—The cell used in this stage is similar to that used in stage 1, except that the magnesium lead alloy produced in stage 1 forms the molten anode, while the cathode consists of a large number of small diameter steel rods immersed to a small depth in the electrolyte, which has the same composition as that used in stage 1. Suitable means are provided for the removal of the molten magnesium as fast as it is produced.

It will be realized that this part of the process really consists in the electrolytic refining of impure magnesium. Means are provided to circulate the magnesium lead alloy, which, as it becomes depleted of magnesium, is returned to stage 1 to be enriched. The secondary cell, which is worked in series with the primary, operates on 5,000 amp. at 2 volts. It will be seen that the total energy consumption for 100 lb. of magnesium per 24 hours amounts to 8.5 kw.-hr. per lb. of metal produced, giving an energy efficiency approaching 40 per cent. Given pure magnesium chloride, such as is produced by the processes already described, the cells operate with remarkable smoothness and require little attention, save for the changing of the electrolyte and the removal of the metal.

Chlorine Disposal

The disposal of the chlorine from processes of this type, especially when worked on a comparatively small scale, is always a matter of some trouble. The process adopted by the Magnesium Co. overcomes this difficulty in a neat and economical manner. The chlorine is aspirated from the cells and is brought into contact in a series of scrubbing towers with milk of magnesium, produced by suspending the ordinary calcined magnesia of commerce in water. The chlorine is absorbed by the magnesia, and a solution is produced containing magnesium chloride and magnesium chlorate in the proportion of 5 molecules to 1.

This solution is concentrated to such a strength that, on cooling, half the contents of magnesium chloride separates as crystals. Potassium chloride is added to the mother liquors in quantity equivalent to the magnesium chlorate present. Potassium chlorate crystallizes out practically quantitatively; it is washed and recrystallized, and is then ready for the market. The mother liquors from the potassium chlorate crystallization are returned to the system, and are concentrated so as eventually to yield all their magnesium chloride as crystals. The potassium chlorate forms a valuable byproduct; but if for any reason it is undesirable to produce it, advantage may be taken of the well-known reaction whereby, when chlorine is passed into milk of magnesia in the presence of a catalyst, such, for example, as nickel oxide, magnesium chloride only is produced and oxygen liberated.

A Cyclic Operation

It will be realized from the above description that the process forms a complete cycle, and really consists in the indirect separation of magnesium and oxygen, in that, apart from the production of the byproduct, potassium chloride, the only raw material is magnesite. The chlorine is being continually separated from the magnesium in the electrolysis, and the same chlorine continually used for the production of more magnesium chloride from magnesite.

The magnesium produced is, as would be expected, of remarkable purity (over 99.5 per cent), and it is interesting in this connection to note that metal of this purity may be melted in open vessels without risk of burning.

Properties of Magnesium

To repeat what has been previously stated, there is no doubt that magnesium, either alone or in alloys, has big possibilities. It is 40 per cent lighter than aluminum, and, when pure, is no more susceptible to atmospheric corrosion than is aluminum. It can be rolled and extruded. As a deoxidizer of other metals it is unrivaled, and its use in this direction is continually extending. It is a minor constituent of many valuable alloys. Alloys in which magnesium is the major constituent are already in use in cases where combined lightness and strength are desirable. Given a corresponding demand, there is nothing to prevent magnesium being put upon the market at the same price as aluminum.

The writer is indebted to the Magnesium Co. for the details describing the process and the many interesting interactions connected therewith.

Graphic Analysis of Sublimed White Lead

By Burton Paxton

WITH the increased use of sublimed white lead as a paint pigment has come a demand for a rapid method of analysis.

Early methods of analysis of this pigment required determination of ZnO, Pb and SO_3; calculation of SO_3 to $PbSO_4$ and residual lead to PbO. This was shortened by Schaeffer's method as given in Scott, "Standard Methods of Chemical Analysis." In this method the Pb and ZnO are determined and by means of formulas calculated to $PbSO_4$ and PbO.

Explanation of the Chart

In order to escape the determination of SO_3 and at the same time eliminate the calculations, the accompanying chart was devised. The left-hand scale of the chart is graduated from 5 to 10, representing percentage of zinc oxide in the pigment. Right-hand scale is graduated from 65 to 70, representing total lead in the pigment. The two center scales are graduated in terms of lead sulphate and lead oxide. A line drawn across the chart connecting any point (*a*) on the ZnO scale with any point (*b*) on the Pb scale will intersect the center scales at percentages of lead sulphate and lead oxide contained in pigment having *a* per cent of ZnO and *b* per cent of Pb.

How to Use the Chart

To use the chart it is necessary to have percentages of Pb and ZnO in the pigment. These may be determined quite rapidly by volumetric methods as follows:

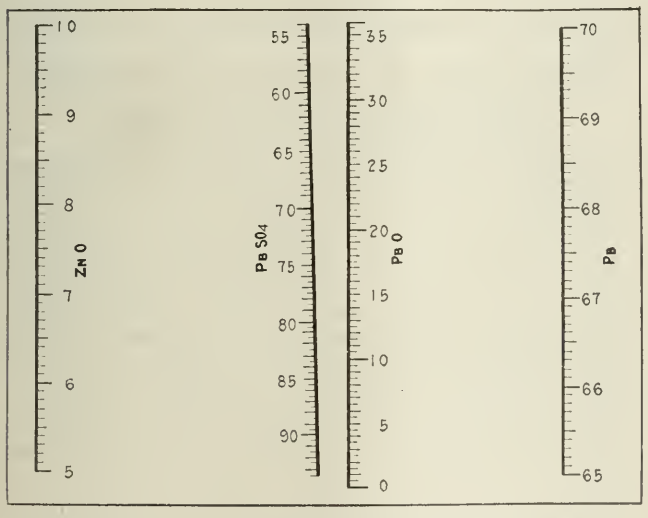

CHART FOR GRAPHIC ANALYSIS OF SUBLIMED WHITE LEAD

For ZnO.—Boil 1 gram of pigment in 6 c.c. HCl, 30 c.c. H_2O and 5 grams NH_4Cl. Pigment will not all dissolve, but this has no effect on result. Dilute to 250 c.c. with hot water, add a few drops of 10 per cent sodium sulphite solution and titrate with a standard solution of potassium ferrocyanide, using ammonium molybdate as an outside indicator. Ferrocyanide solution should equal 0.01 gram ZnO per c.c.

For Pb.—Dissolve 1 gram of pigment in acid ammonium acetate and dilute to 200 c.c. Heat to boiling and titrate hot with a standard solution of ammonium molybdate, using tannic acid as an outside indicator. Molybdate solution should equal 0.01 gram of Pb per c.c.

Now lay straightedge across chart connecting percentage of ZnO on left-hand scale with percentage of Pb on right-hand scale. Intersection of this line with center scales will give percentages of $PbSO_4$ and PbO. The sum of percentages of ZnO, $PbSO_4$ and PbO is, for all practical purposes, a constant, 99.7 per cent.

Using this chart, it is possible to make analysis of pigment in 10 or 15 minutes.

Danville, Ill.

Suggestion for Stopping Demurrage Held Not Authority to Deliver Shipment

A telegram was held not to be authority to a carrier of goods to deliver same in a suit brought by the receiver of Rogers, Brown & Co. against the Chicago, Milwaukee & St. Paul R.R. for the wrongful conversion of a car of soya bean oil, K.T.X. No. 561, and valued at $9,251.75. The oil was purchased by Rogers, Brown & Co. of the Koster Co., which had shipped the oil to its own order to Winnipeg over the named railway, with instructions to notify Royal Crown Soap, Ltd., under an "order bill of lading." Rogers, Brown & Co. purchased the oil, and the bill of lading was indorsed to it, and in due course came into the possession of the receiver.

The complaint alleged that the railroad company delivered the oil without the surrender of the bill of lading to person other than the receiver, or his order. The railway admitted the delivery by it to the Royal Crown Soap, Ltd., and alleged as a defense that upon arrival of the oil at destination it notified the Royal Crown Soap, Ltd., and requested disposition of the car and production and the surrender of the bill of lading. Koster & Co. in turn were notified, who advised that Rogers, Brown & Co. had purchased the draft and bill of lading and were the owners who had been requested to forward the documents. Thereafter the receiver wired the soap company that he was doing all possible to locate documents in order to stop demurrage and suggested that the soap company establish a bond to produce the documents and unload the car. It then further alleged that the soap company advised the railway company of the telegram and the railway company, acting and relying upon such telegraphic instructions, permitted the Royal Crown Soap, Ltd., to unload the car and released the same.

The United States District Court for Washington, Northern District, held that the telegram can in no sense be construed into an order to deliver. It was merely a suggestion as to how the possession of the oil might be obtained before the receiver was able to locate the necessary documents. Nothing in the telegram changed the status of right or obligation of the parties. The loss was occasioned not by anything the receiver did or omitted to do, but rather because the railway company delivered the car without the surrender of the bill of lading, or in lieu of the bill of lading a bond holding the railway company harmless, if the bill of lading is not produced.

Oil Tank Protected From Fire by Cork Insulation

An interesting example of how a material installed for one purpose may render valuable service in a quite unexpected way occurred last summer at the plant of the Island Petroleum Co., Neville Island, Pittsburgh, Pa.

The company had recently completed three steel cold settling tanks, 20 ft. in diameter by 25 ft. high, for bright stock. Being operated part of the time at low temperature produced by brine refrigeration, these tanks were insulated with 3 in. of Nonpareil corkboard. At the time of this incident they were practically filled with oil.

On Aug. 25, 1921, during a violent electrical storm, accompanied by unusually heavy rain, lightning struck one of the crude oil tanks. The resulting explosion released a large quantity of burning oil, which spread out over the partly flooded yard and practically surrounded the nearest settling tank. Hastily constructed dikes shut it off from immediate contact with the others.

For nearly 3 hours the fire raged around this tank, and for almost an hour the flames were leaping directly against its sides, while officials and employees, striving to stop the spread of the fire, momentarily expected the big tank to "let go," with consequent disaster to the entire plant. Three times the hatch on the roof lifted to permit the escape of accumulated gas, but the heat-retarding quality of the corkboard insulation kept the

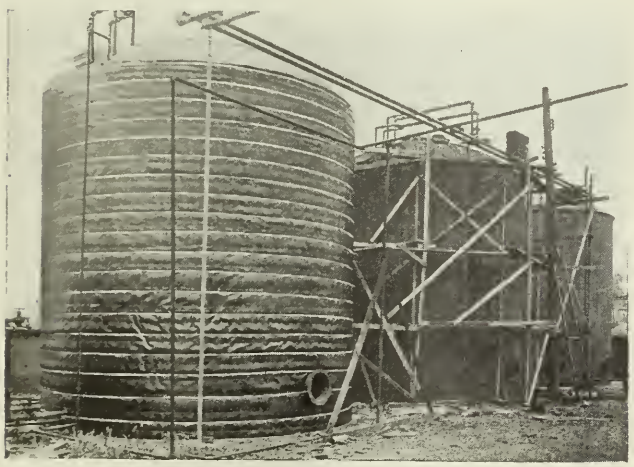

FIG. 1—THE INSULATED SETTLING TANKS OF THE ISLAND PETROLEUM CO., PITTSBURGH, PA.

The tank in the foreground is completed. On the next, the corkboard is in place ready for the jacket of roofing paper. The insulation of the last tank has not been started.

temperature below the danger point, and the fire finally burned itself out with no further loss of property or damage to the insulated tank beyond a slight charring of the outer surface of the corkboard insulation.

The Island Petroleum Co. officials are unanimous in the opinion that the protection afforded by the insulation prevented the destruction of all three tanks and the heavy loss such an explosion would have entailed.

Though insulation may seldom be called upon to withstand so severe a test, the record of this performance is convincing proof of the non-conducting property and fire resistance of corkboard. The same properties have brought the material into favor for the insulation of settling tanks, wax-extraction plants, low-temperature lines, etc. On storage tanks and car tanks for the more volatile oils, insulation, by excluding outside heat,

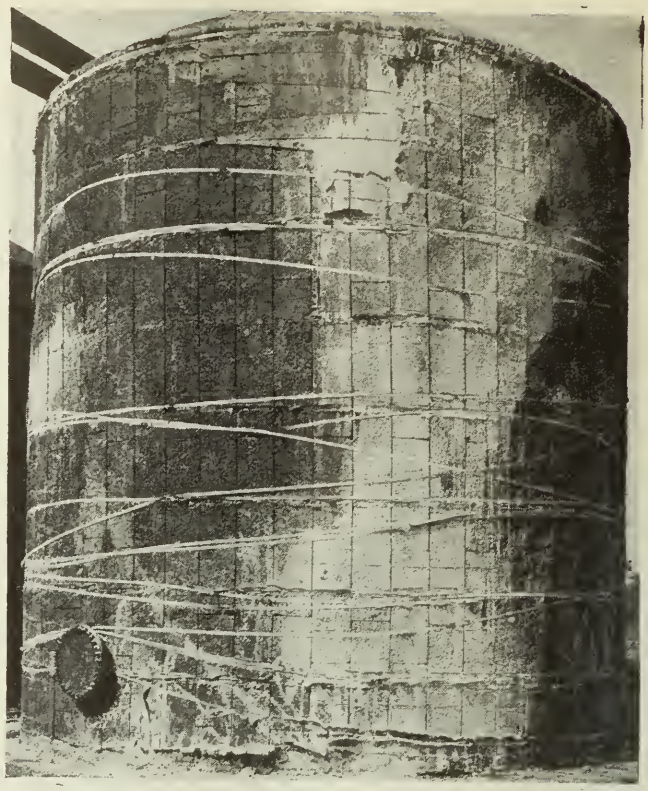

FIG. 2.—AFTER THE FIRE

The jacket has been burned off but the cork, though somewhat charred, is substantially undamaged.

prevents excessive evaporation and reduces the outage to an inconsiderable amount in comparison with the heavy loss sustained when there is no such protection.

Synopsis of Recent Chemical & Metallurgical Literature

Detonation in Internal Combustion Engine.—For a number of years the Bureau of Standards has co-operated closely with the National Advisory Committee for Aëronautics in investigating the performance of airplane and other types of internal combustion engines. This work has included a study of the phenomenon of detonation, and a paper has recently been prepared on this subject which will appear as Technical Note 93 of the National Advisory Committee for Aëronautics, 2722 Navy Building, Washington.

The paper is entitled "The Background of Detonation," and has for its object the discussion of a phase of this question which so far has received but little attention. The effect of the temperature and pressure of the charge before combustion is especially considered, as it is believed that a careful study of this "background" can throw considerable light on results that have been obtained in investigations of detonation both at the bureau and elsewhere.

It is shown that compression and explosion pressures, scavenging and the operation of the ignition system all play a prominent part in the phenomenon of detonation. The influence of changes in fuel characteristics, however, is believed to lie outside the province of this paper and is not taken up in any detail.

Pre-ignition and detonation are conceded to be entirely independent phenomena, and it is shown that overheating troubles are more likely to be from pre-ignition than from detonation. Curves and diagrams showing various phases of the subject are presented, and the whole forms a valuable contribution to the study of the internal combustion engine.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Preparation of Borneol.—Borneol is prepared from oil of turpentine by heating the latter in an autoclave with an ester and then saponifying the bornyl ester produced. The following are given by way of example of the esters employed: Butyl chloride, amyl chloride, camphyl chloride, dimethylethylmethyl acetate and isobornyl acetate; other esters that may be used are salicylates, formates and benzoates. The ester employed is regenerated by combining the acid liberated by the saponification process with the hydrocarbon formed during the ester treatment of the oil of turpentine. (Br. Pat. 174,032. Not yet accepted. L. Peufaillit, Lille, France. March 8, 1922.)

Decolorizing Liquids.—In the process for decolorizing sugar juices and other liquids by means of adsorbents and reducing agents described in the parent specification, formaldehyde-sulphoxylic acid or its salts, such as sodium formaldehyde-sulphoxylate, is used as the reducing agent. (Br. Pat. 174,027. Not yet accepted. J. F. Straatman, Haaksbergerstraat, Holland. March 8, 1922.)

Synthetic Tanning Agents.—Naphthalene, anthracene, phenanthrene or other hydrocarbon at least bicyclic or carbazo, or a halogen or sulphonic acid substitution product, is condensed with a carbohydrate, such as cellulose, starch or their conversion products down to glucose, or with other sugars, in such a way that sulphonic acid groups are contained in the final product—that is to say, sulphuric acid is used as a condensing agent when a sulphonic acid is not employed as a reaction material. According to the example, naphthalene is condensed with cellulose in the presence of concentrated sulphuric acid; the product is neutralized with lime, filtered, the soluble calcium salt decomposed with sodium carbonate and the filtrate evaporated to dryness. The resulting soluble compound can be used as a tanning agent or for the production of lakes from basic dyestuffs, particularly in the presence of metallic salts such as aluminum sulphate. The provisional specification states that any derivative, except hydroxy derivatives, of the above-mentioned hydrocarbons may be used. (Br. Pat. 173,881. Badische Anilin & Soda Fabrik, Ludwigshafen. March 8, 1922.)

Red Iron Oxide.—Red oxide of iron, in a form suitable for use as a pigment, is obtained by roasting in air a mixture of ferrous chloride with excess of barium carbonate. A solution of ferrous chloride, for example galvanizer's waste pickle, neutralized, is mixed with witherite, which is ground so that it passes through a 30-mesh sieve, but is retained by one of 150-mesh. The witherite is present in an excess of from 50 to 100 per cent over the theoretical quantity. The solution is evaporated to dryness and the product roasted at 300 deg. C. until the reaction is complete. The mass is treated with water, which dissolves the barium choride, and forms a suspension of iron oxide, from which the unchanged witherite quickly settles. The oxide is filtered, washed and dried, and barium chloride obtained from the filtrate by evaporation. The process may be modified by adding to the original mixture a finely divided iron compound, which is decomposed under the conditions of the process. Hydrated ferric oxide, ferrous carbonate and iron pyrites are suitable compounds. Two examples of the working of the process are given. (Br. Pat. 174,306. D. Tyrer, Stoneleigh, England. March 15, 1922.)

Extraction of Sulphur From Gas Purification Mass.—Sulphur is extracted from charcoal which has been employed as a contact mass for removing sulphuretted hydrogen from gases by oxidation with air, by means of ammonium sulphide solution. The solution is boiled in a still, the vapors passing to a condenser and the condensed ammonium sulphide runs through a vessel containing the spent charcoal; the solution, saturated with sulphur, flows back to the still, in which sulphur accumulates. On continuing the distillation the condensate eventually becomes practically free from ammonium sulphide and serves for finally washing the charcoal, after which it is diverted into a receiver. The precipitation of the sulphur in the still may be facilitated by adding an electrolyte—for example, salt. The parts of the apparatus which are exposed to the ammonium sulphide solution are preferably made of or coated with aluminum or its alloys. Specifications 13,383 (1911) and 1415 (1914) are referred to. The provisional specification refers to the extraction of sulphur from exhausted gas-purification masses in general. (Br. Pat. 174,143. Badische Anilin & Soda Fabrik, Ludwigshafen. March 15, 1922.)

Chlorinating Acetylene.—The chlorination of acetylene is rendered controllable and does not result in polymerized products by conducting it in the presence of water vapor at high temperatures—for example, 400 to 500 deg. C.—with or without the aid of catalysts such as chlorides of copper, iron or calcium. By an adjustment of proportions, temperature and gas velocity the reaction is made to proceed in any desired direction. The products can easily be separated by fractionation. According to an example, acetylene, chlorine and superheated steam in the proportions by volume of 1:2:12 are passed at the rate of 15 liters per hour through a pipe containing refractory clay at 500 deg. C. and the product consists of dichlorethylene, trichlorethylene, tetrachlorethane and higher chlorination products in the proportions 1:6:6:1. (Br. Pat. 174,635. Not yet accepted. Holzverkohlungs-Industrie Akt. Ges., Baden, Germany. March 29, 1922.)

Fatty Acids.—Fatty acids are obtained by the oxidation of liquid hydrocarbons by means of air or oxygen in the presence of a base with or without other catalysts, provided the liquid hydrocarbons are first freed, say by treatment with fuming sulphuric acid, from constituents which tend to form resinous or asphaltic bodies. The preliminary refining may, however, be dispensed with wholly or in part, if the reaction-promoting agents formed by blowing the liquid hydrocarbons in an acid medium are added to the hydrocarbons before the treatment in the presence of a base, or if the liquid hydrocarbons are first blown in the presence of acid and the oxidizing treatment then continued in the presence of a base. Specification 148,358 is referred to.

In a second patent by the same patentees, the base referred to above is specified as an alkaline earth or magnesia, preferably dry slaked slime, and the oxidation is carried out step by step, the detrimental reaction products being removed between the steps, say by filtration. (Br. Pat. 174,642 and 174,643. Not yet accepted. H. Winternitz, T. Bullinger and G. Teichner, Vienna. March 29, 1922.)

Alcohols.—Alcohols are prepared by passing a mixture of the vapor of the corresponding aldehyde and hydrogen over finely divided copper obtained by the reduction, preferably at a low temperature, of copper compounds which have not been prepared by precipitation and whose preparation has not involved temperature of glowing heat and above. Activators may be added to the catalysts. The following examples are given of the preparation of catalysts for the production of ethyl alcohol from acetaldehyde, methanol from formaldehyde and benzyl alcohol from benzaldehyde: (1) Pumice is coated with copper powder and water glass solution or colloidal silica; the copper is then oxidized at 200 deg. C. and finally reduced at 200 to 250 deg C.; (2) copper formate is brought on to pumice and then treated with hydrogen; (3) lumps of malachite are reduced at 200 to 250 deg. C. The catalysts described in the parent specification may also be employed for the production of other alcohols than ethyl alcohol. (Br. Pat. 175,238. Not yet accepted. Badische Anilin & Soda Fabrik, Ludwigshafen. April 5, 1922.)

Removal of Phenols From Waste Liquors.—Phenols are removed from waste waters by extraction with benzene after acidifying, preferably by treating with acid resins obtained in benzene purification; for further use, the benzene is freed from phenol by means of caustic soda solution. A process and apparatus are described for removing phenol from alkaline waste waters from ammonia works. The waters are freed from solid matter by settling, acidified, preferably by passing part of them through acid resins, and agitated with benzene or "another organic liquid produced by the pyrogenic decomposition of coal or brown coal"; the waste liquid is run off and the benzene agitated with caustic soda solution to remove phenol; fresh waste liquid is then run into the benzene and so on. The caustic soda solution is used repeatedly. The residue from the acid resins used in the neutralizing process may be used as fuel or as insulating material. (Br. Pat. 175,285. Not yet accepted. Posseyer Abwasser- und Wasser-reinigungs Ges., Essen. April 5, 1922.)

Tanning.—Hides are soaked in slightly acidulated water before treatment with lime in the hair-removing process, so that the hair or wool, which retains a relatively large amount of the acidulated water by capillarity, is not attacked by the lime, which nevertheless easily traverses the skin after neutralizing the acid held therein. The soaked hides are piled in pairs with their skin sides together, each pair being separated by a waterproof fabric to protect the hair from the lime in the adjacent skin, and are treated in the usual manner with a somewhat larger amount of lime. (Br. Pat. 175,620. Not yet accepted. Soc. de Feutre, Paris. April 12, 1922.)

Potassium Chloride.—Rocks containing potash, such as leucite, are treated in counter-current in a furnace with gaseous hydrochloric acid, the temperature being about 600 deg. C. at the outlet and 300 deg. C. at the inlet end. The chlorides other than alkali chlorides are decomposed by the time the material reaches the outlet end, and the chlorides are leached out from the product. The hydrochloric acid may be produced by the Hargreaves process, using the potassium chloride produced by the main process, the hydrochloric acid being used directly in the hot state. (Br. Pat. 175,348. G. A. Blanc and F. Jourdan, Rome. April 12, 1922.)

Hydrogen.—In the iron-steam method of manufacturing hydrogen, producer gas is used to reduce the iron oxide, the spent producer gas being utilized in a gas engine. The exhaust gases from the engine are employed to heat the iron-oxide retorts and to raise steam. To produce mixtures of nitrogen and hydrogen, a portion of the spent producer gas is mixed with steam and passed over a catalyst, and the carbon monoxide and carbon dioxide are removed in any well-known way. (Br. Pat. 175,501. J. Harger and Woodcroft Manufacturing Co., Ltd., Liverpool, April 12, 1922.)

Dyeing Cellulose Acetate.—The partial or superficial saponification of cellulose acetate threads or fabrics by alkaline agents prior to or during dyeing is regulated or controlled by the addition of sodium chloride or sulphate or other alkali salts of strong mineral acids in concentrations up to 5 per cent. These salts may be partly replaced by sodium acetate described in specification 176,034 or by the salts specified in specification 175,486. Specification 169,741 also is referred to. According to the provisional specification, the invention is not confined to the above-mentioned salts or concentrations.

A second specification by the same patentee covers the regulation of the partial or superficial saponification of cellulose acetate threads or fabrics by alkaline agents prior to or during dyeing by the use of alkali silicates, aluminates or borates, used either alone or with added alkali. Water-glass is preferred; when used alone it should be employed in such quantity that after the saponification the residual alkali retains the silicic acid in solution. Sodium acetate may be added as described in specification 176,034. Specification 169,741 also is referred to. (Br. Pat. 175,485 and 175,486. British Cellulose & Chemical Manufacturing Co., London. April 12, 1922.

Book Reviews

AMERICA'S POWER RESOURCES. By *Chester G. Gilbert* and *Joseph E. Pogue*. New York: The Century Co. 325 pp. 37 figures. Price, $2.50.

It does a technical man good once in a while to get a broad economic picture of important national problems. This volume gives a splendid portrayal and interpretation of the energy resources—coal, oil, natural gas and water power—in their relation to industry. The presentation is simple and straightforward, clearly intended to make a popular and very general appeal to non-technical readers; but this only makes the work the more readable for the technical man.

The sound reasoning which the authors apply to the problem will furnish the chemical engineer interested in fuels and fuels processing a splendid foundation on which to stand in his consideration of new energy supply questions. The work is based upon the extended study made of the same subject by the two authors while they were connected with the Smithsonian Institution. Many readers after consideration of this brief volume will wish to get the more detailed studies which were prepared on some phases of the general topic and issued as bulletins of the National Museum.

It is to be hoped that a large number will read the book and profit by its arguments. A general appreciation that the maintenance of higher standards of living for the American people can be based only upon a more efficient utilization of energy resources and application of machine power cannot help but be beneficial to the community as a whole. The authors have clearly and convincingly demonstated this thesis. R. S. McBride.

ZIRCONIUM AND ITS COMPOUNDS. By *Francis P. Venable*. American Chemical Society Monograph Series, 173 pp. 23x15 cm. New York: The Chemical Catalog Company, Inc., 1922. Price $2.50.

The author takes cognizance of the growing technical and commercial importance of zirconium in the prefatory statement, "My purpose has been to give a systematic, clear and sufficiently full account of the chemistry of zirconium which should prove useful in connection with the increasing interest attaching to this element."

The first chapter on the history of the element opens with the pertinent statement, "While this element is widely distributed and fairly abundant, its similarity in general properties to other so-called earths, especially alumina, the difficulty of separation from them and the absence of any easy characteristic test caused it to escape the notice of the earlier chemists." There is an interesting account of the occurrence of zirconium, showing its remarkably wide distribution, together with the fact that although the element as such is comparatively new, mention is to be found of jacinth, the natural silicate, in the writings of the ancients.

A succinct statement of the properties of the element which conduced to the failure of the earlier investigators in their attempts to prepare it introduces the reader to the chapter on the element and its properties. There follows an account of the work of several workers in which the difficulties of the task are quite obvious. The work shows the need of careful and exact determinations of many of the physical constants, the present values being uncertain and sadly lacking in agreement.

In the form of the oxide ZrO_2 this element exhibits properties tending to mislead the investigator. On page 40 we read, "When zirconia is ignited, it becomes practically insoluble in all acids except hydrofluoric. The discrepancies in the statements as to its solubility in other acids seem to be due to differences in the degree of ignition."

One finds on reading the account of the qualitative methods of separation and detection that with one exception all the reactions recommended as being distinctive with zirconium salts and therefore adapted to their identification, are given by some others. The exception is notable and

described by the author as follows on page 121: "Biltz and Mecklenburg recommended a most delicate and useful qualitative test. The solution supposed to contain zirconium is strongly acidified with nitric or hydrochloric acid. A few drops of sodium phosphate are added and the solution warmed. A white, gelatinous precipitate is given when as little as 0.0005 per cent of zirconia is present. No other element known to the authors gave such a precipitate in strongly acid solution. Iron, aluminum, the rare earths, beryllium, titanium, thorium and silicon gave no reaction. When a mineral is to be examined, it can be fused in a soda bead in the oxidizing flame, the bead dissolved in excess of hydrochloric acid, boiled, filtered, and a drop of the phosphate solution added. The test is not applicable if phosphoric acid is present in the mineral."

"Zirconium in combination with a volatile or organic acid is usually determined by direct ignition and weighing as ZrO_2." Causes of error in this method are given, one being retention of a small quantity of the volatile acid radical by the oxide formed and the other being losses due to carrying away of light particles of oxide by gas currents. Errors in the quantitative determination result from adsorption of soluble salts by precipitated hydroxides, explosion of hydroxide on ignition, and hydrolysis and consequent loss of weight of certain precipitates on washing.

Most of the methods of separation from other elements are disposed of by referring the reader directly to the original literature on the subject. The cupferron method is discussed in some detail. Being accurate, simple and quick, the selenious acid method of Smith and James might well have been included in this chapter.

As one would expect from the presentation of the properties of the various zirconium compounds found in former chapters of this volume, the chapter upon technical applications comprehends a great variety of uses, many of which are the subject of patents. Precious stones, oxy-hydrogen light, gas mantles, incandescent filaments, reduction of metals, alloys, furnace applications, refractories, enamels, glass, textile applications, colloidal applications, medicinal, abrasive and chlorinating agent comprise the list.

Under the heading alloys there is discussed the possibility of using certain zirconium alloys as incandescent lamp filaments. "Such filaments are claimed to have the power of selective radiations—in other words, emit more light than corresponds to the temperature to which they are heated by the electric current. This implies a considerably lower wattage per candle power than is now required by the average metal filament lamp."

The volume includes an interesting, useful patent list, with a short abstract of each patent, also a comprehensive bibliography which includes all the patents given and to which reference is constantly made in the text.

From the nature of the element there is undoubtedly more than the usual amount of conflicting data and discrepancies to be found in the literature, from which in each case the most reliable work has been selected with a discrimination which evidences an accurate comprehensive, experimental knowledge of the subject.

PHYSICAL CHEMISTRY FOR COLLEGES. A Course of Instruction Based Upon the Fundamental Laws of Chemistry. First Edition. By *E. B. Millard*, Assistant Professor of Physical Chemistry, Massachusetts Institute of Technology. International Chemical Series, H. P. Talbot, Ph.D., Consulting Editor. New York: McGraw-Hill Book Co., Inc., 370 Seventh Ave.; London: 6 and 8 Bouverie St., E.C., 4. 1921. vii + 411 pp. 61 figures. Price $3.50.

"This book has been prepared to bring before college students certain of the more important aspects of physical chemistry, together with accurate modern data which illustrate the applicability of its laws to the phenomena observed in the laboratory. It has been assumed that the student is familiar with inorganic and analytical chemistry, that he has had an adequate course in college physics and that the simple processes of calculus are familiar to him.

"No attempt has been made to cover the whole of physical chemistry in a single volume; its most important topics have been treated at such length as the size of the volume allows, and numerous references to recent periodical literature are included for those who would pursue any given topic further.

"The limitations of the orthodox laws of physical chemistry have been emphasized more than is commonly done in beginning courses of physical chemistry. To this end the illustrative data have been carefully chosen from modern experimental work, in order to minimize the 'experimental errors' which are so often used to conceal real deviations of a law from the facts it is intended to express. A trusting belief in inadequate physical laws will only retard the scientific progress of a student, and weaken his faith in adequate laws; whereas a wholesome appreciation that physical chemistry is an unfinished and growing science may stimulate thoughtfulness and research. The proper time to encourage a research attitude is in the very beginning of a student's chemical career."

With the above sentiments all modern physical chemists will be perfectly in accord, and in the hands of a capable and conscientious teacher Prof. Millard's book will undoubtedly be an admirable and inspiring text for college students. The various topics are presented in simple and entertaining style, and a sincere effort has been made throughout to enable the thoughtful worker to obtain an exact idea of the present status of our knowledge on each point.

The most serious criticism that can be raised is that the text assumes too much on the part of the teacher, and it is to be feared that a student forced to make his way through the volume without more than the average available amount of direction would be likely to emerge with a very confused idea of the fundamentals of the science. In the attempt to include minor details of recent advances, the early development and the intimate correlation of the different branches of the subject are often totally neglected. Important relationships, such as the ideal osmotic pressure equation on page 142, the van't Hoff equation for the change of equilibrium point with temperature on page 251 and the Gibbs-Helmholtz equation on page 399, are introduced quite casually without any hint as to their derivation. Unless the groundwork in each case is added by the instructor, the knowledge gained must evidently be merely empirical.

The best chapters are those on Radioactivity and Atomic Structure. The exercises at the end of each chapter are carefully selected, and cannot fail to be of great value to the student.

JAMES KENDALL.

* * *

GAS CHEMISTS HANDBOOK. Compiled by the Chemical Committee Technical Section of the American Gas Association. New York: Second edition. 608 pp., 113 illustrations. Price $6.

This volume should be in every gas works and coke-oven laboratory, for most of the methods in it can be recognized as standard for these industries. Others who have any problems of testing or analysis in connection with gas works raw materials, products of gas manufacturing or impurities in gas will also do well to study these methods carefully.

The committee in the second edition of the handbook has followed its earlier policy of using methods which have been approved by the A.S.T.M., the American Chemical Society, Bureau of Standards and Bureau of Mines. This policy of following standard procedures adopted by associations or government institutions adds greatly to the value of the work. This plan should certainly be encouraged and followed in future editions as they may become necessary.

As in any volume which is a composite of the work of numerous authors, the text lacks somewhat that finish of style and that uniformity of presentation which makes a book most attractive. However, as this is largely a reference work for use of laboratory men, the defect is not really serious. It would have been desirable, however, if a greater uniformity in illustrations had been found possible. Many of these illustrations are excellent, certainly a great improvement over the earlier edition; but there is still room for improvement, as many of the drawings are by no means as carefully made as the value of the work would justify.

R. S. MCBRIDE.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

American Institute of Chemical Engineers Holds Conference on Chemical Engineering Education

At the invitation of the American Institute of Chemical Engineers, representatives of a score of colleges, together with a number of prominent chemical engineers, met at the Brooklyn Polytechnic Institute, Tuesday, May 16. The meeting was called to consider the reports of the Institute's committee on chemical engineering education. This report was based upon an extensive questionnaire on the curriculum of chemical engineering courses offered at seventy-three institutions in this country. These results were tabulated, and on a basis of these tabulations, fourteen recommendations were made. The report is a thorough and admirable work.

The meeting was called to order by President Henry Howard of the American Institute of Chemical Engineers. He introduced President Atkinson of the Brooklyn Polytechnic Institute, who made a short address of welcome to the conference. Dr. Atkinson said that he felt that some of the evils apparent in chemical engineering education were due to the fact that quantity production was the primary aim. He urged upon the conference the desirability of having the students undertake actual industrial work as a part of their technical courses.

Secretary Olsen called the roll of the conference and the following men were present:

Educators—F. W. Atkinson and J. C. Olsen of the Brooklyn Polytechnic Institute; S. T. Arnold, Brown University; Edward Bartow, State University of Iowa; R. M. Bird, University of Virginia; F. E. Breithut, College of the City of New York; C. W. Crockett, University of Maine; John Frazier, University of Pennsylvania; T. B. Freas and D. D. Jackson, Columbia University; R. T. Haslam and W. K. Lewis, Massachusetts Institute of Technology; J. H. James, Carnegie Tech.; R. R. Renshaw and Henry Masson, New York University; Allen Rogers, Pratt Institute; R. L. Sackett, Pennsylvania State College; R. S. Tour, University of Cincinnati; H. M. Ullmann, Lehigh University; A. H. White, University of Michigan; James Withrow, Ohio State University.

Chemical Engineers—A. D. Little, of A. D. Little, Inc.; Henry Howard of the Grasselli Chemical Co.; J. B. F. Herreshoff, General Chemical Co.; F. W. Frerichs, Herf & Frerichs; Charles L. Reese, du Pont company; T. B. Wagner, U. S. Food Products Corporation; G. E. Walker, Dorr Co.; Charles D. Allen and W. C. Bainbridge, H. Kohnstamm & Co.; A. Trowbridge, National Industrial Conference Board; R. T. Stokes, of the *Journal of Industrial and Engineering Chemistry*, and H. C. Parmelee, Ellwood Hendrick, S. D. Kirkpatrick and Charles Wadsworth, 3d, of Chemical & Metallurgical Engineering.

The secretary then read a number of letters from institutions too far away to be represented, all expressing great interest in the conference.

Engineers Express Views on Education

Arthur D. Little of Boston, chairman of the Institute committee, was asked by President Howard to take the chair. Dr. Little began by reading one by one the recommendations which the committee had made, and calling for objections to the recommendations as they stood. In this preliminary discussion ten of the recommendations were approved without change and four were reserved for discussion at the afternoon session. Dr. Little then called on a number of chemical engineers to express their views with regard to the products which the educational institutions are turning out under the name of "chemical engineer."

Henry Howard of the Grasselli Chemical Co. said that he felt that most of the chemical engineers lacked initiative and originality. He did not know whether these attributes could be supplied by education, but felt that the problem should be considered. The young chemical engineer seems to him to lack a knowledge of how to undertake problems, and his suggestion was to train not specialists, but engineers who have breadth of point of view. Charles L. Reese, chemical director of the du Pont company, made a very strong plea for training in English and said that he believed this to be the greatest lack in chemical engineers at the present time. He would prefer a man who had been well trained in chemical theory rather than the ordinary chemical engineer, but admitted that the demands of the du Pont company differ from those of smaller organizations. J. B. F. Herreshoff of the General Chemical Co. felt that perhaps the greatest lack in chemical engineering training was that men were not able to think methodically. What is needed in industry is men who can talk well, think well and write well, he said. Able criticisms of present chemical engineering education were also made by T. B. Wagner, F. W. Frerichs and R. S. Tour.

Dr. Little closed the morning session with a few extracts from the Mann report on engineering education. The conference then adjourned to the Brooklyn Chamber of Commerce, where informal luncheon was served.

Educators Express Views

In the afternoon session the educators, who may be considered the producers of the chemical engineer, were given an opportunity to express their views on chemical engineering education and to suggest changes which would be beneficial. Discussions centered around some of the moot points of the Little report. Prof. James of Carnegie Tech. contended that business training for chemical engineers was highly desirable, especially for those who went into smaller companies. Companies such as the du Pont organization might not find such training necessary, but subjects such as commercial engineering should, in his opinion, be included in the training of a chemical engineer. Another point raised by Prof. James was that engineering subjects, such as mechanical engineering, applied mechanics, strength of materials and such courses, should be given to chemical engineers in somewhat condensed form, as minor subjects, much as chemistry is given in condensed form to medical students.

Dean Sackett of Pennsylvania State College Engineering School felt that it would be distinctly unwise to omit subjects such as might be included under industrial engineering and plant management from the curriculum of the chemical engineer. He further made a plea for the 4-year course in chemical engineering, stating that such a course should be a general course and that special subjects should be taken up as graduate subjects, preferably in institutions specializing in such subjects. This, he said, would make for economy in educational institutions. He was somewhat opposed to special courses in English, economics, etc., because he felt that good English and fundamental principles of economics could be taught through courses in engineering. The writing of reports could be just as efficacious in teaching the students good English writing as random subjects in English composition. It would be much easier for the student to recognize economic principles employed in connection with engineering problems in the courses which he had to take. Dean Sackett stated in clos-

ing that courses in chemical engineering should do their best to increase the interest of the student in the human side of his profession.

A reading knowledge of a modern language was considered very desirable, and both French and German were felt to be necessary, although many of those present believed that high school preparation would eliminate the necessity of taking up either or both of the languages in a technical course already crowded with subjects. Prof. Lewis of the Massachusetts Institute of Technology made a strong plea against overcrowding the curriculum of the chemical engineer. Four years were in his opinion nearly filled with mathematics, physics, chemistry and chemical engineering. It should be urged on the students that four years cannot possibly turn out a finished chemical engineer and that professional success can come only with continued study after graduation. The technical school then should confine itself to subjects which it is difficult to study away from the institution. Such subjects as chemistry very properly should be majored in institutions, whereas subjects such as industrial engineering, in Prof. Lewis' opinion, should be postponed until the student has graduated, for such a subject he could well undertake himself.

The M.I.T. System

Dr. Haslam of the Massachusetts Institute of Technology described the Technology system and told how it worked. In brief, there are three stations to each of which fifth year students in chemical engineering are sent for two months. Each one of these stations is in charge of a director and an assistant director, both of whom are members of the faculty of the Institute. Each station is connected with two manufacturing plants and the students spend one month in each of the plants. The program in each plant is somewhat similar. During the first week a flow sheet or description of the manufacturing process is made out by the student, after which investigative tests are organized. These tests are designed by the director of the station and are carried out by the students. They are not intended to study the operation of the plant as such. In other words, the fact that the men are working in a sugar refinery is not the significant fact. Primarily, they are studying filtration in the sugar refinery and they concentrate on "unit studies," such as grinding, filtration, evaporation, heat transfer, etc.

The students thus are given a six months' course in plant research. Specific problems in industry are being studied from the point of view of the chemical engineer. The students solve these problems themselves under competent guidance. They organize the tests, decide what data are necessary, make sure that the data are taken accurately, and record the data themselves. Considerable interest was evidenced on the part of the conference in this new and apparently successful experiment.

Dr. Allen Rogers of the Pratt Institute told something of the work which is done at his institution in training, not chemical engineers, but chemical foremen. This work also was followed with great interest.

Recommendations Adopted

The recommendations of the Institute committee as finally adopted by the conference were as follows:

1. An undesirable multiplicity of subjects is now included in courses in chemical engineering.
2. Wherever possible it is desirable to avoid splitting major courses into a number of minor courses.
3. Any course in chemical engineering should provide, as the background for specific instruction in chemical engineering as such, strong courses in chemistry, physics, mathematics and the fundamentals of engineering.
4. As preliminary to the desirable reorganization of chemical engineering courses, steps should be taken to secure agreement on the nomenclature concerned with the subjects involved.
5. A much closer agreement in the weighting of the various courses as to clock and credit hours is urgently needed in those institutions giving courses in chemical engineering.
6. The committee would omit from chemical engineering curricula courses in civil engineering, sanitary engineering, mining engineering (except geology), and electrical engineering beyond its fundamentals, which should include the instruction required for the erection and operation of motors and generators.
7. It is desirable to avoid specialization by industries in the 4-year course in chemical engineering. When specialized training is offered, the specialized subjects should preferably be segregated as post-graduate work. This applies to such subjects as petroleum technology, sugar, cellulose technology, fuel and oil, and refrigeration.
8. The committee considers a thorough grounding in English, a reading knowledge of some foreign language and a reasonable familiarity with English literature essential to the adequate training of the chemical engineer, and regards English as one of his most effective working tools. It recommends a special course in report writing and the oral presentation of projects.
9. The committee recommends that a "source of information" course or its equivalent be provided as a part of the chemical engineering course. This specialized course should familiarize the student with patent literature, governmental reports, bibliographies, trade journals and catalogs, abstract journals, publications of societies and other technical literature, the resources of libraries and the activities of scientific and technical organizations throughout the world.
10. The committee recommends that wherever possible, engineering studies should be preceded by 3 years of general college training, in which special emphasis be given to mathematics, physics, chemistry, English history and economics, with the idea of obtaining a broad foundation for their professional study and of entering upon this study at a greater maturity and with presumable reduction of time required for their professional courses.
11. The committee wishes to emphasize the fact that the chemical engineering profession is a difficult one and that, accordingly, a thorough and broad preparation for entrance should be insisted upon by institutions offering courses in chemical engineering.
12. The committee recommends that technical schools and professional schools of universities arrange their courses so that properly qualified college graduates may secure a professional degree at the end of a two-year course.
13. The committee deprecates the use of undergraduate or even graduate students as major instructors (instructors of laboratory sections or quiz sections) in charge of classes of chemical engineering, even in the freshman year.

The conference voted that the chairman appoint a committee to carry on the work and to call a second conference at some future time. Dr. Little urged the members of the conference to suggest the names of members of the committee to him. A vote of thanks was passed to the Brooklyn Polytechnic Institute for its courtesy in housing the conference.

Modern Trend of Engineering in Public Service Indorsed by Heating and Ventilating Engineers

Eulogizing the report of the committee on elimination of waste in industry of the Federated American Engineering Societies as a "notable and outstanding" achievement in the public interest, a report of the committee on industrial reconstruction of the American Society of Heating and Ventilating Engineers urges active engineering participation in the national effort to solve the pressing problems of industry. The committee was appointed to study some of the questions of industrial reconstruction and to seek to co-operate with the committees of other engineering societies to ascertain avenues for public service by engineers.

It is the intention of the Society of Heating and Ventilating Engineers to associate with the Federated Societies as soon as its finances permit.

Lime Association to Meet in Cleveland

The annual convention of the National Lime Association will be held June 14 to 16, at the Hotel Statler, Cleveland, Ohio. The activities of this convention will deal with the technology of the uses of lime and the industrial problems of manufacturing and marketing lime.

Differences Between Importers and Alliance Aired Before Dye Investigation

Additional testimony relating to the importers' view of the dye situation was presented before the Senate investigating committee by Paul Pickhardt, of Kuttroff, Pickhardt & Co., in the dye hearings last week. In addition to Senator Moses' complaints against the administration of the licensing system which Mr. Pickhardt voiced at his first appearance, the latter presented a lengthy recital of his own activities and those of his firm in connection with the importation of German dyes. His testimony was designed to show that all of the activities of himself and of his company were proper and did not merit the condemnation and criticism that he said previous witnesses before the committee had expressed. Mr. Pickhardt read quotations from communications between his firm and the German cartel, and between various officials in the United States and American representatives in Paris dealing with the dye situation. These showed, he said, that statements and inferences made against the activities of his firm were not justified and that his company had acted within its rights at all times.

Again Attacks Textile Alliance

Mr.Pickhardt again emphasized his contention that the German manufacturers desired to have all dyes wanted by the United States, other than those controlled by the Reparation Commission, imported through the firm of Kuttroff, Pickhardt & Co., and he again attacked the prominence of the Textile Alliance in importing German dyes for consumers. The intention of the Germans, he said, was that Kuttroff, Pickhardt & Co., be the sole importing agency of all other than reparation dyes.

His company had returned 188 import licenses to the consumers for whom they had obtained them, he said, because the Textile Alliance was able to secure the dyes at a cheaper price. These licenses were the property of the consumers and should be turned back to them, he felt, rather than turned over to the Textile Alliance, although the consumers themselves gave the licenses to the Alliance to fill.

Derides German Bugaboo

Efforts have been made, continued Mr. Pickhardt, to impress upon the country the great power of the German chemical cartel and the danger of the cartel securing a hold on this market through importers. "As a matter of fact," he said, "any hold that may be obtained will be through the quality of their goods or their prices, and whether that hold comes through importing agencies or an official agency makes little difference."

"Reference has been made to the danger of German dumping," he continued. "It must be remembered that the Germans are in a commercial business. Before the war $11,000,000 would cover the entire market in the United States. The consumption of German dyes in the United States was not over 15 per cent of the total world consumption. It is scarcely probable that the Germans would disturb prices all over the world, including all other markets where they now can make a profit, in order to dump dyes in the United States. They would be throwing a world market away for a comparatively small part of it. The statement that the German cartel would be willing to spend $50,000,000 dumping dyes in the United States in order to destroy the American industry is absurd."

Textile Alliance Offers Defence

W. B. Denton, treasurer of the Textile Alliance, presented a statement from A. M. Patterson, president of the Alliance, replying to Mr. Pickhardt's charges against that organization. The statement declared that the Textile Alliance has had only the same sources of information that are open to Kuttroff, Pickhardt & Co. He added that the delays in receipt of reparations dyes charged to the administrators of the system by Mr. Pickhardt were caused by the efforts of importers, present or former agents of the cartel, to delay and block the deliveries of reparation and "Herty option" dyes to consumers in the United States.

Mr. Patterson replied to a number of other charges by Mr. Pickhardt and stated in conclusion that the rights to the reparation dyes guaranteed and safeguarded by the treaty with Germany can be maintained only through a government agency or a nominee acting for the American public and the consuming trades.

Howe Explains C.W.S. Exhibit

The importance of chemistry to national defense, as well as to medicine and to industry and science, was emphasized by H. E. Howe, formerly of the National Research Council, in his testimony on May 20 before a special session of the committee. Dr. Howe explained the chemical exhibit which was prepared under the auspices of the National Research Council with the co-operation of the Chemical Warfare Service of the United States Army. The exhibit was prepared, he said, to educate the public to the vitally important part in our national existence played by chemistry. The exhibit now is permanently installed at the Smithsonian Institution in Washington.

New Proposal for Government Operation of Muscle Shoals in Senate

Senator Norris of Nebraska has introduced a bill for the operation of the Muscle Shoals nitrate plants by a government corporation to be known as the Federal Chemical Corporation. The bill was prepared by ex-Representative Lloyd of Missouri.

The proposed corporation would continue for 50 years and would have seven directors, of whom three would represent the government by selection of the Secretaries of Treasury, War and Agriculture. These three directors would have the same power as the other directors of the corporation and in addition would control the sale and distribution of nitrates and fertilizers produced. The other four members of the board would be selected at the annual meeting of the stockholders of the corporation and hold office for one year.

The offices of the corporation would be established at Muscle Shoals and in Washington. The capital stock would be $5,000,000 divided into 50,000 shares of par value $100.

The bill provides for the lease of the Gorges steam plant and transmission lines with all the plants and dam at Muscle Shoals for a period of 50 years. The corporation would complete the construction projects now under way, including Dam 3 and its proposed power house. Under the provisions of the bill, the corporation would immediately adapt the nitrate plants for the production of fertilizers, the selling price of which would be fixed by the government directors. The bill would also provide that the lessee give to the government, for its protection, a bond in the sum of $1,000,000 to be approved by the Secretary of the Treasury for the faithful performance of the provisions of the lease, which would be renewed every 5 years. In event the bond were not renewed at the expiration of any 5-year period the lease would terminate and the government take possession.

Redmanol Company Consents to Decree and Will Manufacture Under License of Bakelite Co.

The Redmanol Chemical Products Co. has made a settlement of the recent action by the General Bakelite Co. against the General Insulate Co. for infringement in the use of Redmanol by the last named company. This action though brought against its customer was defended by the Redmanol company.

Judge Chatfield rendered a decision sustaining the Baekeland patents, covering broadly, on the one hand, the combination of phenol condensation products with fiber and fibrous materials, and on the other hand the simultaneous use of heat and pressure in the manufacture of articles made from these products.[1] The Redmanol company has now consented to a decree and paid heavy damages in liquidation. Redmanol henceforth will manufacture under license.

The validity of the Baekeland patents is thus confirmed. Previously their validity had been acknowledged by the Condensite Co. of America, a licensee of the General Bakelite Co.

The products of these three companies are well known under trade names of Bakelite, Redmanol and Condensite.

[1] See Chem. & Met. Eng., vol. 25, p. 279, Aug. 17, 1921.

Tariff Discussion in Senate Drags Through 100 of 2,057 Committee Amendments

It took the Senate just a month to consider the less controverted committee amendments to the chemical schedule of the tariff bill. The rates prescribed for coal-tar products, which can be considered only in connection with the administrative provision providing for a continuance of dye and chemical control, are yet to be discussed. With the single exception of American valuation, the dye controversy is the principal storm center of the entire bill.

The chemical schedule contains eighty-eight paragraphs. Some of the more disputed of these have gone over for future consideration. When it is considered that there are 1,690 paragraphs in the bill, in addition to the special provisions and the administrative features, the enormity of the task of putting through tariff legislation under Senate rules, under which it is very difficult to restrict debate, can be realized. The eighty-eight paragraphs in the chemical schedule cover more than 6,000 items. As a consequence, the rate of duty is of concern to a very wide range of industries. Senators anxious to present the viewpoints of constituents are never lacking in material to bring before the Senate regardless of the importance of the item. The bill contains 2,057 committee amendments. During the first month of the consideration of the bill one hundred of that number had been considered.

In this particular bill the special provisions and administrative features represent departures in policy. As a result those provisions will come in for lengthy discussion. They cover 196 of the 438 pages of the bill.

Eyes on the Calendar

Senator Harrison of Mississippi, who is opposed to the passage of the bill, stated on the floor of the Senate May 16 that "the plan of the majority is to allow the consideration of the pending bill to occupy a long time in the Senate—to permit it to drag along for months and months. Then the bill will go to conference. It will stay in conference during the election. Then Congress will adjourn without a tariff bill having been passed."

Five hours and forty minutes was consumed in the discussion of the five-line alcohol paragraph before the committee amendment was voted on. This is typical of the procedure on numerous other items which are by no means storm centers in the bill. "Senators on the other side," said Senator McCumber, who is in charge of the bill, "disclaim any purpose whatever to delay the consideration of this bill. They speak earnestly of their desire to facilitate its progress. They remind me of the poem of Kipling's bear, as they look at us and speak to us like a man in the attitude of prayer, professing their innocence of any intention to filibuster."

Borah Would Postpone Consideration of the Bill

That the Republicans are not a unit in their support of the bill is becoming increasingly evident. Senator Borah boldly stated on the floor of the Senate that the facts at hand are insufficient upon which to base an intelligent tariff bill at this time. "I would vote unhesitatingly," he said, "to postpone consideration of the bill and to take care of the situation by a simple addition to the emergency tariff law. I do not know where we can get facts as to the cost of production abroad. I do not see how it is possible to secure them. The facts available today will be swept away utterly tomorrow, so that there are no facts upon which we can base an intelligent opinion. I do not believe it is possible to make a tariff law of permanent worth under such conditions."

While it is known that certain Republican Senators are not enthusiastic about the bill, there can be no denying that the majority leaders are doing all in their power to expedite its consideration.

Ammonium Nitrate Off Free List

At the last minute the committee changed its mind with with regard to the action it would take on ammonium nitrate. This commodity had been placed on the free list, but on reconsideration the committee decided to recommend that it be made dutiable at one cent per pound. It was contended that the byproduct coke industry must be encouraged, and since such a duty would not be in the interest of a monopoly but in the interest of a very large number of separate concerns, the committee finally determined to give it protection to the extent of 1 cent a pound. It was admitted that the Republicans on the Finance Committee were closely divided on the matter, but the Senate supported the 1-cent duty by a vote of 35 to 24.

By a vote of 32 to 24 the rate of 50 per cent ad valorem on trichlorethylene was reduced to 35 per cent. It was pointed out by Senator Willis of Ohio that it is important to use this chemical in the decaffeinization of coffee in that it does not explode like benzene. This permits the carrying on of this operation within city limits where it otherwise would be barred by fire regulations.

The duty on dry, ground, bolted or precipitated chalk was reduced from 35 per cent to 20 per cent ad valorem. The rate on putty was increased from ½ to ¾ cent per pound, while the manufactures of chalk not specially provided for were put back to the House rate of 25 per cent ad valorem. The committee also receded from its proposal to make ethers and esters not specially provided for dutiable at 30 per cent ad valorem. The House rate of 25 per cent was restored.

King Would Reduce Barium Rates

As fast as he could offer them the Senate rejected amendments of Senator King to reduce the duties on barium products. By a vote of 41 to 15 it rejected his amendment to reduce the duty on barium carbonate from 1 to ¼ cent a pound, and the committee duty of 1 cent a pound was adopted, 38 to 15. By a vote of 36 to 13 the Senate rejected King's amendment to reduce the duty on barium chloride from 1¾ cents to ¼ cent a pound, and adopted the committee duty without division. An amendment by the Senator reducing the duty on barium hydroxide from 1¾ cents to ¾ cent a pound was defeated, 40 to 12, and another amendment reducing the duty on barium nitrate from 2½ to 1½ cents a pound was defeated, 39 to 13.

This brought up the matter of a proposed duty on manganese, which product the Finance Committee had placed on the free list. Senator Smoot of Utah said the controlling factor which induced the committee to place manganese on the free list was a report of the Geological Survey to the effect that there were no deposits in this country of sufficient content to enable them to be worked profitably.

New Jersey Chemical Society Enjoys Annual Outing at Princeton

A more beautiful day for an outing could not have been desired than Saturday, May 20, when the members of the New Jersey Chemical Society journeyed to Princeton for their annual ladies' day, as guests of the Chemical Society of Princeton University. The Princeton campus, with its shaded walks, expansive lawns and well-kept gardens, was at its best. Campus and buildings were thrown open to the visitors, and little groups of chemists wandered through the grounds as their fancy led them. Many of the members found their way to the athletic field and saw Princeton triumph over Harvard in the dual track meet. Late in the afternoon light refreshments were served in Murray Dodge Hall, after which the members gathered at a theater just off the campus, where A. C. Fieldner, of the Pittsburgh Experiment Station of the Bureau of Mines, spoke on the timely subject of the ventilation of vehicular tunnels.

Mr. Fieldner's talk was illustrated with slides and motion pictures showing the experimental mine constructed at Pittsburgh in which were carried out the studies that supplied data for the design of the new Hudson River tunnels. The studies of effect of small concentrations of carbon dioxide on the workers were described, as were the elaborate chemical and physical tests on the rate of flow of air, its optimum humidity and the heat conductivity of the tunnel walls.

Dinner was served in the beautiful graduate school dining room to eighty members and guests. Beyond a brief word of appreciation for Princeton's hospitality there was a refreshing absence of speechmaking, and the guests enjoyed a sociable hour before returning to their homes.

New Merchant Mill Planned by Tennessee Coal, Iron & R.R. Co.

Official announcement is made by George Gordon Crawford, president of the Tennessee Coal, Iron & Railroad Co., that a combination 10- and 12-in. merchant bar mill, two blocks long by 80 ft. wide and having a monthly capacity of 10,000 tons of plain or deformed bars, rounds and squares, is to be built at once at the works of the Tennessee company in Fairfield, a suburb of Birmingham. While the cost of the new mill has not been officially announced, it is stated unofficially that the figure will be approximately a million dollars.

The new merchant mill will be so located as to receive billets from the Fairfield blooming mill, to which tables will be added so that long billets can be delivered to the merchant mill without the necessity of switching cars. It will consist of a roughing train of six strands of 10-in. rolls, an intermediate mill of five strands of 12-in. rolls and a finishing train of two strands of finishing rolls, provided with 11-in. pinions, making it possible to use either 10-in. or 12-in. rolls.

A mechanical hotbed 255 ft. in length will receive the hot bars from the roll trains and, after cooling, the bars will be sheared and stocked in a stores and shipping room specially adapted for the storing of concrete reinforcing bars and with storage capacity for a limited tonnage of merchant bars. The bar mill and stocking building will be 80 ft. wide and 820 ft. long. The capacity of the mills is estimated at 10,000 tons of plain or deformed bars, rounds or squares per month. The mill is to be built to care for the increased demands for bars in the Southern territory and for export. Material for the construction of the mill will be ordered at once and construction will begin as soon as the materials are received.

New Strike Indicates Large Northern Oil Field

The Troy-Sweetgrass Co. has struck oil at a depth of 1,750 ft. in a test-bore that the company was sinking at a point 12 miles southeast of Kevin, Mont. The oil is said to be of the same grade as that found at Kevin about 2 months ago, and would seem to indicate that an important new oilfield has been discovered. When oil was found at Kevin, S. E. Slipper, of the Canadian Geological Survey, after making an examination of the oil, stated emphatically that he believed an important new field had been discovered, and that the geological structure of the country in southern Alberta would lead him to suppose that the field is likely to extend into that province nearly as far as the Saskatchewan River. The recent discovery of very "wet" gas near Medicine Hat would seem to bear out Mr. Slipper's prediction. The Troy-Sweetgrass Co. will enlarge the bore, so that oil may be pumped from the well.

Tile Manufacturers Exhibit Varied Products

The Associated Tile Manufacturers, co-operating with the American Institute of Architects, held an exhibit of tiles and tile work and presented a series of illustrated addresses at the Cosmos Club, Washington, D. C., May 12 to 15, inclusive. The exhibit was largely of samples of tiles for house and building finish or decoration. The possibilities of utilizing colored and figured tiles for both exterior and interior was particularly emphasized. Among the speakers were Frank Upman, Albert Kelsey, D. Knickerbocker Boyd and A. L. Harris, architects, and F. W. Walker, secretary of the Associated Tile Manufacturers.

Carnegie Tech Students Join Industrial Engineers

A chapter of the Society of Industrial Engineers was recently organized among students at Carnegie Institute of Technology, Pittsburgh, to be known as the Carnegie Industrial Engineers Society. This is the third chapter to be organized in the country.

The department of machine construction, under Prof. Charles C. Leeds, organized the chapter, which includes 108 members. Sophomore, junior and senior students taking 4-year degree courses in the colleges of engineering and industries are eligible, but a satisfactory scholastic standing must be maintained to hold membership.

Fellowships Offered at Washington and Alabama

The College of Mines of the University of Washington offers five fellowships for research in mining, metallurgy and ceramics in co-operative work with the Bureau of Mines. The fellowships are open to graduates of universities and technical schools who are properly qualified to undertake research investigations. The value of each fellowship is $780 per year of 12 months, beginning July 1. Fellowship holders are required to register as graduate students and to become candidates for the degree of master of science in mining engineering, or metallurgy, or ceramics, unless an equivalent degree has previously been earned.

The School of Mines of the College of Engineering of the University of Alabama also offers five fellowships in mining and metallurgical research in co-operation with the Bureau of Mines. The fellowships are open to graduates of universities and engineering schools who have proper qualifications to undertake research investigation. Conditions are the same as mentioned above.

The Co-operative Department of Mining Engineering of Carnegie Institute of Technology, Pittsburgh, announces the offer of two fellowships in mining research and two in teaching and research, in co-operation with the Pittsburgh Experiment Station of the United States Bureau of Mines. Fellowships are open to graduates of universities and technical schools who are properly qualified to undertake research investigations. The value of each fellowship is $750 per year of 10 months beginning July 1 for the position of research fellow and Aug. 1 for teaching fellow.

International Chamber of Commerce to Hold General Meeting in Rome

The next general meeting of the International Chamber of Commerce will be held in Rome, Italy, the week of March 19, 1923. In arriving at this decision the board of directors of the International Chamber, which just met in Paris, was influenced to a great extent by the possibilities of the Genoa Conference.

Before this meeting the International Chamber committees, consisting of experts in financial and commercial problems, will be able to consider the results from the Genoa Conference in so far as they affect industry and commerce. Based on the views of these committees, constructive plans will be made at that time as to such further steps which should be taken in restoring the trade of the world.

The Congress planned for next spring will be the first meeting of the International Chamber to be held in Italy. As it is to be held early in the year, it is expected that large delegations of business men from the twenty or more countries connected with the International body will attend.

New Fertilizer Plant in Florida

Work has begun on the factory of the Non-Acid Fertilizer & Chemical Co., which will manufacture finished fertilizer from phosphate taken from its own mines in Polk county, Fla. The plant will be completed in time to begin filling orders by Aug. 1, according to backers of the enterprise.

The plant, which will have a capacity of 40,000 tons a month, is located on the main line of the Atlantic Coast Line R.R., 1½ miles south of Lakeland. When completed it will have a complete mixing plant capable of converting the raw phosphate into finished commercial fertilizer. The company owns several tracts of phosphate lands in the Lakeland and Mulberry district and will mine its own raw material. The main building will be 80x300 ft. and 150 men will be employed.

Says Freight Rates Keep Up Fertilizer Prices

Fertilizer prices are discussed by Chairman Anderson of the Joint Agricultural Commission in a report on the effect of railroad rates on agriculture and basic commodities. "Fertilizer prices are now close to the pre-war basis except for the higher freight costs now prevailing," he said. "Material prices and costs of manufacture are almost back to normal, leaving the present freight costs almost entirely responsible for the difference between present cost of fertilizer and that which prevailed prior to the war."

American Section, Society of Chemical Industry, Holds Symposium on Activated Carbon

Of rather unusual interest, partly because of the comparatively recent development of the subject and partly because of its wide industrial application, was the conference on activated carbon held by the American Section of the Society of Chemical Industry in New York, May 19. Two papers on different phases of the subject were presented and the discussion which followed was general and animated.

Activated Carbon and Its Uses

Dr. A B. Ray, of the National Carbide & Carbon Co., took as his subject "Activated Carbon and Its Uses." Although handicapped considerably by lack of facilities for projecting his carefully prepared stereopticon slides, Dr. Ray went into the theory of activated carbon and its application in industry in a lucid and interesting manner. Activated carbon apparently has a distinct physical form. Amorphous carbon, aside from its occurrence as diamond and as graphite, occurs in two forms, one of which is active, while the other is not. The active form is prepared by the carbonization of nut shells or lignite at low temperatures, giving a product which is known as primary carbon. This is not absorptive, since it is apparently already saturated with stabilized hydrocarbons. The process of activation consists in breaking down this complex of stabilized hydrocarbons by treatment with saturated steam, by differential oxidation or by a chemical treatment with lime or zinc chloride. Active and inactive carbon differ in the temperature of formation, the active modification being formed at temperatures between 500 and 600 deg. C.

The absorptive power of the carbon depends upon two characteristics of the substance, its specific absorptive capacity and its capillary absorptive capacity. Dr. Ray described tests developed during the war for the determination of these two quantities by saturating and then evacuating a sample of carbon. By far the largest part of the absorbent power of the carbon is due to its specific absorption power, and this portion is also most readily recovered. He also described the iodine test for determining the capacity of the substance for absorbing complex substances from solution. For this phase of selective absorption, porosity is a requisite of the material as well as activity. The porosity is determined by measuring the apparent density in a specially designed apparatus.

Application of Activated Carbon in Industry

Activated carbon is finding application in industry in three main fields, for absorbing gases, absorbing substances from solution and as a catalyst. For the first purpose, the carbon must have a high retentivity and be structurally strong. It is being used for removing toxic vapors from air, in solvent recovery, extracting gasoline from natural gas, sulphur compounds from coal gas, purifying hydrogen, separating mixed gases, manufacturing helium, obtaining high vacuums and in purifying carbon dioxide and ammonia. As an absorbent for substances in solution it is used in refining sugar, organic acids, glycerine, gelatine and glue, pharmaceuticals, mineral acids, alkaloids and decolorizing waxes.

G. A. Burrell described in greater detail the application of activated carbon to the extraction of gasoline from natural gas, a process which seems to promise relief for the motor fuel situation of the future. Dr. Burrell pointed out how the tremendous demand for motor gasoline has forced the refiners to cut deeper and deeper into the petroleum to produce lighter fractions for this purpose. The product so obtained is low grade and has to be mixed with natural gasoline to make it fit for use as a fuel.

Both of the ordinary processes of removing gasoline from natural gas have their disadvantages, the compression process involving high losses due to the liquefaction of butane, which then absorbs hexane, and the oil absorption process demanding considerable handling of solvent oil. There are three plants in commercial operation at the present time, according to Dr. Burrell. A unit consists of three absorbers, one of which is absorbing while one is being evacuated and the other is cooling. By this process it is said that a very superior grade of gasoline is produced, averaging 7 to 8 lb. vapor pressure.

Expect Good Representation at Annual Exposition of Chemical Industries

The Eighth National Exposition of Chemical Industries will be held this year in the Grand Central Palace, New York, Sept. 11 to 16. It will follow immediately upon the fall meeting of the American Chemical Society.

The managers report that three full floors and part of the fourth of the Grand Central Palace are already taken for the exposition. There are this time 350 exhibitors who have contracted for their space locations. In the exposition there are two special sections, one upon the subject of fuel economy, where exhibits intended for the more efficient use of fuel, its combustion, distribution or control will be made; another where the subject of shipping containers will be given considerable attention and will have to do with the container itself, whether of metal, wood, fiber, paper or the cooperage of slack or tight barrels, tanks and towers with machinery for packaging, labeling, handling and conveying the packaged material and lastly making it ready for final shipment. This section will furnish the complete ideal for any industrial plant. There will be groups of exhibits of glass and ceramic products. Laboratory equipment will be thoroughly represented. There will be a group of Canadian exhibits where the natural resources of the adjoining dominion will be made and there will also be a Southern section where not only the resources of our South but of the manufactured products coming from that section will be made.

The program of the exposition has been outlined and work is now in progress upon it, and it may be expected to compare fully with the high standards of the preceding expositions. As has been the custom, there will be exhibits of motion pictures covering all phases of the chemical industries and the exposition will hold much of interest for every visitor.

New Chamber of Commerce Building Dedicated

In the presence of representative business men from all parts of the country, the cornerstone of the new home of the Chamber of Commerce of the United States was laid May 17, on the site of Daniel Webster's old home, facing the White House.

As expressed by Joseph H. Defrees, president of the National Chamber, the proposed new building was dedicated to industry and commerce on the basis that "if it is not for the common good it is not good for business."

The speakers were Secretary of Commerce Hoover, former Secretary of Commerce and Labor Charles Nagel, L. S. Gillette of St. Paul, chairman of the building committee, and Harry A. Wheeler, Chicago banker, the first president of the Chamber.

Safety Institute Extends Activities

The Safety Institute of America has recently announced the appointment of Dr. C.-E. A. Winslow as health supervisor. It is planned to broaden the program of the organization to include, in addition to the prevention of accidents, the general problems of factory sanitation, personal hygiene of workers and treatment of injuries and disease. One section of the Institute's permanent museum of safety will be devoted to industrial hygiene and will include exhibits dealing with lighting, ventilation, dust removal, factory seating, etc.

International Commercial Exposition in Mexico

An invitation to attend the Second International Commercial Exposition in Mexico City, Aug. 15 to Sept. 15, 1922, has been extended to American manufacturers, exporters and business men through the Mexican Chamber of Commerce of the United States. Sept. 16 is the national independence celebration day in Mexico. Mexico City has the largest number of visitors during the two or three weeks previous to that date. A great percentage of the merchants throughout the republic and the well-to-to people go to Mexico City to do their purchasing and make their connections at this time.

Civil Service Openings for Chemists

The U. S. Civil Service Commission announces open competitive examinations for the following positions:

Laboratory assistant, senior grade, at salary of $1,200 to $1,380 per year. Examinations will be held June 7 and 8 and July 19 and 20, 1922.

Laboratory assistant, junior grade, $1,000 a year. Senior aid, $900 a year. Examinations June 7 and July 19, 1922.

Application for the above should be made at once on form 1312.

New Soda Factory in Indo-China

The large factory for the manufacture of soda and by products by the Société Industrielle de Chimie d'Extrême-Orient, is practically completed. The factory is on a deep-water site near Haiphong, and is considered to be the most important and modern plant in the Orient. It represents an expenditure of 11,250,000 francs. The company expects to supply a large number of paper, glass, soap and spinning factories in the Orient with caustic soda and other chemicals.

Paper Mill Operates Largest Electric Boiler

An electric steam boiler, said to be the largest ever built, was recently put in operation by the Laurentide Paper Co. The boiler is designed for 25,000 kw. and is being run at 34,000 kw., producing 100,000 lb. of steam per hour at 125 lb. pressure. The boiler was constructed and installed by the Dominion Engineering Works, Montreal.

Personal

Dr. Edward Bartow, head of the department of chemistry, State University of Iowa, intends to sail for Liverpool on June 3. He also intends to visit a number of places on the Continent and will attend the International Union of Pure and Applied Chemistry, at Lyons, France.

Dr. William Blum, of the Bureau of Standards, who has been suffering severely through difficulty with his eyes, is recovering slowly from this trouble as a result of a recent operation. His friends will be pleased to know that the doctors give great encouragement regarding complete recovery, though he will still be compelled to refrain from much active work for some time to come.

John V. N. Dorr, president of the Dorr Co., of New York, is on a 2 months' business trip and expects to visit the principal European countries. He will make his headquarters at the offices of the Dorr Co. at 16 South St., London, E. C., and expects to return to New York in July.

H. C. Fuller addressed a joint meeting of the Chemical Society of Washington and the American Pharmaceutical Association, Washington branch, on May 11, on the subject "The Chemist and the Druggist." A series of motion pictures was shown descriptive of the manufacture of industrial alcohol and several other related topics.

W. H. Fulweiler, of Philadelphia, has been selected to serve on the new executive committee of the Division of Research Extension of the National Research Council.

Captain D. P. Gaillard, who has for several years been in the Nitrate Division of the Army, has been permanently transferred from Washington. He is now Ordnance representative at the Old Hickory Ordnance Reserve Depot, Jacksonville, Tenn. At that station he will be the representative of the army in matters relating to the sale of property which was formerly the Old Hickory powder plant, located near Nashville, which is being disposed of by the National Industrial Corporation, under a contract with the government.

H. W. Hardinge has left for a tour throughout the West to make a general survey of conditions in both the mining and industrial fields.

Kotaro Honda, professor of metallurgy at the Imperial Japanese University, Sendai, was presented with the Bessemer Medal of the British Iron and Steel Institute in recognition of his researches into the magnetic properties of iron and steel. He has established the theory of molecular magnetism, based on the measurement of the amount of change of the volume in the steel when magnetized, and his researches led to the discovery of one of the best materials for the manufacture of permanent magnets.

Milton Kutz, for the past 25 years with the Roessler & Hasslacher Chemical Co. and during the last 12 years manager of the Philadelphia office, is now located in New York as manager of sales.

Dr. C. E. Kenneth Mees gave a lecture on May 12 on "A Photographic Research Laboratory" before the Northeastern Section of the American Chemical Society at Rochester, N. Y.

Dr. G. A. Menge, formerly with Libby, McNeill & Libby, has opened an office as consulting chemist at 111 West Monroe St., Chicago, Ill.

Dr. R. B. Moore, chief chemist of the Bureau of Mines, is en route to Europe on an official visit to study developments in radium, rare metals and rare gases. In addition he will make observations as to the potash and dye industries. Dr. Moore also will carry credentials from the Chemical Warfare Service and will look into certain matters of chemical development in which that Service is much interested. His itinerary includes London, Paris, Berlin, Prague, Vienna and Leyden. He has accepted an invitation to deliver several lectures while in Prague.

Prof. W. Nernst on April 1 took over the duties of director of the Physikalisch-Technische Reichsanstalt, but will continue to act as rector of the University of Berlin until Oct. 15.

H. C. Parmelee, editor of Chemical & Metallurgical Engineering, addressed the Chemical Society of the Massachusetts Institute of Technology on "The Chemist in Public Life" on May 11.

L. D. Perry, treasurer of the Central Iron & Steel Co., Harrisburg, Pa., has resigned. He has been connected with the company for about 10 years.

Prof. R. S. Tour of the department of chemical engineering, University of Cincinnati, spoke before the Affiliated Technical Societies of Detroit on Friday, May 19. His subject was "Some Technical and Economic Considerations of the Muscle Shoals Development."

E. A. Wilson, director of the pyralin research laboratory of E. I. du Pont de Nemours & Co., is resigning to engage in the practice of chemical engineering.

David Wing, who has been associated prominently with many of the government's activities touching coal, has been designated by Secretary of Commerce Hoover to act as the department's point of contact with trade associations desirous of discussing plans for submitting their statistical data to the department.

Prof. J. R. Withrow of the Ohio State University will sail for Europe June 13 on the Empress of France. He intends to make an extended trip through France, Italy and Switzerland.

At the meeting of the National Academy of Sciences, held in Washington on April 26, members were elected as follows: Edward W. Berry, professor of paleontology, Johns Hopkins University; George K. Burgess, Bureau of Standards; Rufus Cole, director of the hospital of the Rockefeller Institute for Medical Research; Luther P. Eisenhart, professor of mathematics, Princeton University; Joseph Erlanger, professor of physiology, Washington University Medical School; Herbert Hoover, Secretary of Commerce; George A. Hulett, professor of physical chemistry, Princeton University; Charles A. Kofoid, professor of zoology, University of California; George P. Merrill, curator of geology, U. S. National Museum; C. E. Seashore, professor of psychology, State University of Iowa; Charles R. Stockard, professor of anatomy, Cornell Medical College: Ambrose Swasey, president of the Warner & Swasey Co.; W. H. Wright, astronomer, Lick Observatory, University of California. Dr. Albert Einstein, of the University of Berlin, was elected a foreign associate.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Standard Working Hours of Factory Employees

An inquiry regarding standard working hours in New York State, which has recently been completed by the Industrial Commissioner of that state, has brought to light some information of interest to executives in the chemical and allied industries. It is evident from this compilation that over half of the factory employees in New York State work on an 8-hour basis, since the group "45 to 48 hours" shown in the accompanying table accounts for 50.2 per cent of the total and an additional 10 per cent are found in the group "44 hours or less." The chemical industries show even a larger proportion of plants reporting the standard 8-hour day. Leather, glass and lime factories would appear to have longer working hours than the average for all industries. The paper mills, on the other hand, reported the shortest hours of any of the industries considered.

It is interesting to know that in 1913 the 9-hour day was the prevalent working day in New York State, although almost as many wage earners were working 10 hours a day. The longest working hours in 1913 were in the stone, clay and glass industries and in the pulp and paper industry. The latter group reported the greatest reduction in working hours of any industry—from weeks of "over 63 hours" in 1913 to 48 hours in 1921. This reduction is the result of the change in that industry from two-shift to three-shift operation, which changed the working day from 11, 12 or 13 hours in continuous processes to 8 hours.

The chemicals, oils and paints industry is one of the few groups in which working hours in 1921 are shorter up state than in New York City. There are, however, more employees on a 44-hour week in New York City than outside of the city. The low hours in the city are found chiefly in the animal and mineral oil products division. Up state three-quarters of the chemical group and most of its subdivisions work an 8-hour day.

Hours of Labor According to U. S. Census

The returns of the 1919 census of manufactures indicate a general and marked decrease in the prevailing hours of labor throughout the entire country. Of the 9,096,372 wage earners reported by that census, 4,418,693, or 48.6 per cent, were employed in establishments where the prevailing hours of labor per week were 48 or under, while in the previous census, covering the year 1914, the number employed in this class of establishment was only 833,330, representing 11.8 per cent of the total number of wage earners.

The establishments in which the hours of labor were 48 per week in 1919 employed 32.6 per cent, or about one-third of the total number of wage earners, and those in which the hours were less than 48 employed 16 per cent of the total.

In 1914, 74.6 per cent of the total number of wage earn-

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	160.49
Last week	160.20
May, 1917	222
May, 1920	279
April, 1918 (high)	286
April, 1921 (low)	140

Cottonseed oil was almost entirely responsible for the slight advance over last week's index number. The only other commodity to show an increase was crude potassium carbonate. Slightly lower prices were noted for 66 deg. sulphuric acid, ammonium sulphate and caustic potash. The prices of the other chemicals included in this index number remained unchanged.

WAGE EARNERS IN MANUFACTURING INDUSTRIES OF U. S.

	1919 Number	1919 Per Cent of Total	1914 Number	1914 Per Cent of Total
Prevailing hours of labor per week:				
48 and under	4,418,693	48 6	833,330	11.8
44 and under	1,111,107	12.2	(a)	....
Between 44 and 48	346,179	3 8	(a)	...
48	2,961,407	32.6	(a)	....
Between 48 and 54	1,496,177	16.4	945,735	13.4
54	828,353	9.1	1,818,390	25.8
Between 54 and 60	1,248,854	13.7	1,543,018	21.9
60	827,745	9.1	1,487,801	21.1
Over 60	276,550	3.0	407,973	5.8
Total	9,096,372	100 0	7,036,247	100.00

(a) Figures not available for 1914.

ers were employed in establishments where the prevailing hours of labor per week were not less than 54, and 26.9 per cent in establishments operating not less than 60 hours per week. In contrast with this the census of 1919 reported 34.9 per cent employed in the former class of establishments (working not less than 54 hours) and 12.1 per cent in the latter (working not less than 60 hours).

Financial Notes

Virginia-Carolina Bond Issue. A group of New York bankers has underwritten a total of $35,000,000 in bonds of the Virginia-Carolina Chemical Co. Of this amount, one issue of $22,500,000 is of 7 per cent sinking fund gold bonds based on a 25-yr. first mortgage due June 1, 1947. These bonds are offered at 98¾, to yield about 7.12 per cent. The other issue is of $12,500,000 15-yr., 7½ per cent convertible sinking fund gold bonds. It is said that the new financing will provide for the purchase or retirement at or before maturity of all the company's existing funded obligations and will provide additional working capital.

Mathieson Alkali Now Operating at a Profit. The first 3 months of 1922 showed a net profit of $151,667 on the books of the Mathieson Alkali Works, as compared with a loss of $61,571 during the first quarter of 1921. The value of sales for the first 3 months of the current year was $1,418,291, as against $683,858 for the first quarter of last year.

Du Pont Company Applies for Listing. Application has been made for the listing on the New York Stock Exchange of the $63,378,300 outstanding common stock of E. I. du Pont de Nemours & Co. of Wilmington, Del. According to the public announcement made in connection with the application, the company's average annual income for the past 11 years as applied to its common stock has amounted to 54.33 per cent. Commercial business as distinguished from military has accounted for an average of 12 per cent of the net earnings on the common stock during this period. The du Pont company now owns 36.95 per cent or 7,628,137 shares of the common stock of the General Motors Corporation.

Wholesale Prices in April

Both chemical and metallurgical products advanced in price during April, according to the index numbers of the U. S. Bureau of Labor Statistics. The index figure for the group "chemicals and drugs" had remained stationary at 159 for the previous 3 months, but in April it advanced to 160. "Metals and metal products" had been falling off continually since October, 1920, and had reached a low of 114 in March, 1922. The April figure, however, showed an increase to 117. These index numbers are based on a par of 100 for the year 1913.

The general index for all commodities did not change during April, remaining at 152. Of the 327 price series on which this index is based, increases were found to have occurred for 91 commodities and decreases for 100. In the case of 136 commodities no change was reported.

The New York Market

NEW YORK, May 22, 1922.

The chemical market during the past week was somewhat irregular and activity was limited to a few important items. The export interest in solid caustic soda continued along the same firm lines as during the previous week. Inquiries for large tonnages were received from leading European and South American countries and May allotments for standard brands have been well absorbed. The tendency of this market is toward much higher prices. The soda ash market has shown no price changes, but leading dealers believe that this item is about set for a sharp advance. Prussiates have featured the week's trading. Both the potash and soda salts have reached new high levels for the year and considerable consuming interest has been noticed. Supplies of both products have been greatly reduced and buyers are finding extreme difficulty in locating any round quantities. Oxalic acid has shown additional price advances and the market closed in a very firm condition. Salt cake buyers are complaining about the difficulty of procuring any spot supplies. Producers are heavily sold ahead and the market has shown every sign of reaching higher levels. Citric and tartaric acids have continued along steady lines, with trading a trifle under expectations. Copper sulphate has maintained its strong position and agricultural interests have continued to purchase largely. Producers are well sold up for future delivery. Barium chloride was exceedingly scarce during the latter part of the week. Caustic potash has shown some traces of weakness on spot, but several large holders reported a moderate inquiry, with moderate sales at former levels.

General Chemicals

Barium Chloride—Spot goods have been very limited and sellers were enabled to maintain prices at $105 per ton. Only a few odd lots are obtainable in first-hand directions. Shipment material is quoted at $95 per ton, duty paid, with domestic producers holding the same prices, f.o.b. works.

Bichromate of Soda—Trading was along quiet lines, with sales recorded at 7½c. per lb. for small quantities. For carload lots 7¼c. per lb. was quoted. The consuming industries seem to be well supplied by regular standing contracts.

Caustic Potash—General conditions in this product have slightly changed, with the tendency rather downward. The range for the 88-92 per cent imported is 6c. per lb. on spot, although in several directions 5¾c. per lb. was quoted.

Caustic Soda—The foreign inquiry continues along very strong lines and the market retains its former firm position. May shipments of standard brands are quoted nominally at $3.90@$3.95 per 100 lb., with practically no material available. Leading factors report a steady demand for contract deliveries and report the market at 2½c. per lb., basis 60 per cent works. Ground and flake caustic are quoted at $3.65 per 100 lb. in drums and $3.85 in barrels, f.o.b. works, carload lots.

Chlorate of Potash—Imported material was quoted at 7c. per lb. among some of the more important traders, while in other directions it was stated that several odd lots could still be had down to 6½c. per lb. Domestic makers still quote 8c. per lb. works.

Prussiate of Potash—The yellow material is very scarce on spot. In some prominent quarters as high as 32c. per lb. is being asked for limited lots. The red variety remains at 75c. per lb.

Prussiate of Soda—Higher prices have been reported for spot material and the market was in a very firm position during the latter part of the week, with offerings rather scarce. Sales were recorded up to 20c. per lb. and some leading sellers refused to accept business under 21c. per lb.

Salt Cake—Producers of this material are heavily sold up and the market is much stronger than at any time during the past year. The lowest figures heard were $18 per ton, f.o.b. works, and $20@$25 per ton for spot goods.

Soda Ash—Prices are holding quite steady, with leading dealers taking on business in carload lots at $1.90 per 100 lb. in single bags on spot. Barrels are quoted at 2c. per lb. Leading producers offer contracts at $1.20 per 100 lb. for single bags in carload lots and $1.40 for barrels, f.o.b. works.

Coal-Tar Products

The market in the coal-tar products industry during the past week was irregular. Specialties were about the only feature to trading and in most instances the transactions were small and limited only to actual requirements. The phenol market was the outstanding feature, with spot goods exceedingly scarce. A good inquiry for this product was noted for both home consumption and export. Toluene and benzene are well sold ahead and the market remains quite steady. Cresylic acid is maintaining its recent advance and offerings are somewhat limited. Dimethylaniline and dinitrotoluene are a shade easier. Betanaphthol is moving along quietly.

Anthracene—The consuming inquiry for this product has not shown very much activity of late, but leading factors are maintaining former prices. Several sales of the 80-85 per cent were reported at 75c. per lb.

Benzoates—First-hand sales of benzoate of soda were reported at 50@55c. per lb. Benzoic acid prices were heard around 60@65c. per lb. The demand for these products has shown seasonable improvement.

H Acid—Producers quote this product at 85c. per lb., with smaller lots running up to $1. Business is irregular.

Phenol—Former levels are fully sustained by leading dealers and the market is quoted firm at 14@15c. per lb. for prime white, U.S.P. crystals. Offerings are very limited and a good inquiry is reported.

The Chicago Market

CHICAGO, ILL., May 18, 1922.

The tone of the general chemical market showed signs of improvement during the past week, and while no large transactions were reported, business was fairly active in a small way. It is reported that stocks of many items are very low and any unusual demand will cause prices to advance sharply. Foreign material is not very plentiful and what is available is offered at a figure so close to the domestic price that consumers are not interested. Prices in general were quite firm and but few reductions were to be noted. This was particularly true in the fine chemical market, where several sharp advances took place.

General Chemicals

The alkali market was in a very firm position, although the expected advance in prices did not occur. No large stocks of *caustic soda* could be located on spot and small lots were quoted at $3.87 per 100 lb. for the solid and $4.35 for the ground or flake, basis 76 per cent. *Caustic potash* was reported to be moving very well at 6¾c. per lb. for the 88-92 per cent material in drums. This was foreign material and domestic producers were apparently making no effort to sell this market. *Soda ash* was also very firm, with small or moderate lots in cooperage quoted at $2.20@$2.30 per 100 lb.

Alums lacked quotable change and continued to move in a routine way. *Potash alum* was quoted at 4½c. per lb. for the lumps and 5½c. for the U. S. P. powdered. *Barium salts* continued scarce with prices higher. Small lots of *barium chloride* could be had at $130 per ton. *Sal ammoniac* was firm and was reported to be moving fairly well at 7¾c. per lb. for the white granular in cask lots. *Carbon tetrachloride* was slow and resale material was available at 10c. per lb. *Blue vitriol* was in active demand and could be had in one direction at $5.75 per 100 lb. It was reported that in some quarters this material was getting quite scarce. *Furfural* is still quoted at 50c. per lb. in 100-lb. lots. *White arsenic* was firmer at 8@8½c. per lb. for small lots. *Formaldehyde* continued quiet, with consumers interested only in small quantities. This material was offered at 10c. per lb. in single-barrel lots, but it is quite possible that this could have been shaded a trifle. *Glycerine* was dull and c.p. material in drums could be had at 15c. per lb.

Bichromates attracted but little attention and dealers maintained their schedules. *Potassium bichromate* in single-cask lots was quoted at 11¾c. per lb. and similar quantities of *sodium bichromate* at 9c. *Permanganate of potash* was dull and easy at 16c. per lb. for the imported U.S.P. crystals. *Red prussiate of potash* was available in broken lots at 70@75c. per lb. The *yellow prussiate* was in a very strong position at 33@36c. per lb. *Hypo* moved in a routine way to the consuming trade at $3.95 per 100 lb. for the pea crystals in single-barrel lots.

Linseed Oil

A prominent factor in this field reports that *linseed oil* is getting scarce in this market and that higher prices may be expected very soon. The oil is moving very well to the trade and today's market on the boiled oil in 5-drum lots was 97c. per gal., with the usual reduction for raw.

Naval Stores

Turpentine, like linseed oil, is scarce in this market, one factor reporting that he could sell all that he could get. The movement is very good and no one is complaining. Today's price on 5-drum lots was $1 per gal., and an advance was expected. *Rosin* is not so scarce and is moving in a satisfactory volume. The tendency is without a doubt upward, with nearly all factors predicting the advance to take place soon. The G grade was offered today in carlots at $5.85 per keg of 280 lb.

The Iron and Steel Market

PITTSBURGH, May 19, 1922.

Apart from steel involved in freight car and fabricated steel orders there has been a relatively light turnover in finished steel products in the past week, the market having been fairly well sold up into July in the activity that characterized March and April. Producers seem to have the edge—i.e., it is a sellers' market rather than a buyers' market. The tonnage involved, however, is not large.

Activity is restricted because the mills, in general, are unwilling to enter third-quarter contracts, as they are not certain as to the tonnage they will be able to turn out then, on account of the coal strike.

Orders for freight cars reported in the past week total about 9,000, representing an increased rate of buying. About 60,000 cars were ordered in the first 4 months of the year, more than double the number in the entire year 1921. Car buying has been equal to the average in the 10 years before the war, when, however, steel-making capacity was only one-half to two-thirds as great as at present.

Fabricated steel lettings are running heavier than formerly, the average in the past few weeks being 30,000 or 35,000 tons a week. The lettings now approximate the fabricating capacity, while lettings last year represented only 35 per cent of capacity.

Finished Steel Prices

Finished steel prices continue to show a stiffening tendency. Bars, shapes and plates are quotable at 1.60c. on ordinary orders, but on particularly attractive lots shapes and plates would probably go at 1.50c. At the low point in February all three products were quotable at 1.35c. even on small lots. Independents have advanced their price on bands, hoops, and hot rolled strips from 2c. to 2.25c., while the Steel Corporation does not seem to have any regular price. Regular prices on sheets, as advanced $3 a ton early in April, are 2.40c. for blue annealed, 3.15c. for black, 4.15c. for galvanized and 4.50c. for automobile sheets. Six or seven mills are quoting $5 to $7 a ton above these prices, while, on the other hand, the bimonthly wage scale adjustment showed shipments in March and April invoiced at an average of 2.80c. for 26, 27 and 28 gage, the same level as shown by the two preceding adjustments. Tin plate is steady at $4.75.

Steel Production

The Carnegie Steel Co. resumed making ingots at the Mingo plant at the beginning of this week, the two Mingo furnaces that were banked early in April having resumed last week, while the banked Farrell stack is again in operation and the Farrell works, scheduled for resumption early in April, is about to operate. Both plants make sheet bars, the supply of which was beginning to grow scant.

The industry as a whole is producing ingots at a trifle above 37,000,000 tons a year, against rates of about 35,000,000 tons March 31 and 30,000,000 tons Feb. 28. The Carnegie Steel Co., at first affected by the Connellsville strikes, has made various arrangements for fuel supply and is now operating thirty-five blast furnaces, against thirty-four on April 1.

Coal, Coke and Pig Iron

Connellsville coal has advanced sharply in the week, steam grade being now $4.25@4.50. The advance was caused chiefly by continued heavy buying by Eastern consumers, who require some high-volatile coal, not obtainable farther east than the Connellsville region. Coke is a shade easier, with furnace at 6.25@$6.50, foundry remaining quotable at $6.75. There is no regular demand from furnaces. Offerings are very limited.

In coal circles the steel industry is regarded as particularly well stocked with coal. In some quarters it is estimated that the industry has drawn but little upon stocks, having bought coal and coke freely where it could be had, and being very conservative in preparing for a long strike.

The pig iron market has been altogether stagnant. The market is quotable at prices that are more or less nominal: Bessemer, $26; basic, $25; foundry, $24, f.o.b. valley furnaces, freight to Pittsburgh being $1.96.

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.15 — .16
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.50 — .55
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.50 — .55
Beta-naphthol, tech	lb.	.25 — .27
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.53 — .55
Cresylic acid, 95-97%, dark, in drums	gal.	.48 — .50
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.65 — .70
Dimethylaniline	lb.	.36 — .38
Dinitrobenzene	lb.	.22 — .25
Dinitroclorbenzene	lb.	.22 — .24
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .65
H-acid	lb.	.85 — 1.00
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.09 — .11
Monoethylaniline	lb.	1.05 — 1.25
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.08 — .08
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17
Ortho-amidophenol	lb.	2.40 — 2.50
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.70 — .75

Ortho-nitro-toluene	lb.	12 —	.15
Ortho-toluidine	lb.	.14 —	.18
Para-amidophenol, base	lb.	1.25 —	1.30
Para-amidophenol, HCl	lb.	1.30 —	1.35
Para-dichlorbenzene	lb.	.13 —	16
Paranitroaniline	lb.	.75 —	.77
Para-nitrotoluene	lb.	.60 —	.70
Para-phenylenediamine	lb.	1.55 —	1.60
Para-toluidine	lb.	1.0 —	1.10
Phthalic anhydride	lb.	.35 —	.38
Phenol, U. S. P., drums	lb.	.14 —	15
Pyridine	gal.	1.75 —	2.75
Resorcinol, technical	lb.	1.30 —	1.35
Resorcinol, purc	lb.	1.75 —	1.80
Salicylic acid, tech., in bbls	lb.	25 —	25½
Salicylic acid, U. S. P	lb.	26 —	26½
Solvent naphtha, water-white, in drums, 100 gal	gal.	25 —	28
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	10 —	12
Sulphanilic acid, crude	lb.	24 —	26
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	45
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	.33 —	.35
Xylene, commercial, in tank cars	gal.	30 —	....

Industrial

Financial, Construction and Manufacturers' News

Industrial Developments

GLASS—The Thatcher Mfg. Co. has resumed operations at its Clarksburg, W. Va., plant, following a suspension for more than 12 months. The works will operate for the manufacture of bottles, giving employment to close to 100 men.

The F. C. Wheaton Co., Millville, N. J., manufacturer of druggists' glassware, has resumed operations at its North Millville plant. The main Millville works is running full, and it is said that orders on hand insure this basis of operation for some time to come.

The Mississippi Glass Co. is reported to be planning for the resumption of production at its Morgantown W. Va., plant as soon as alteration and improvement work, now under way, has been completed. The factory recently curtailed operations for this purpose.

RUBBER—The Firestone Tire & Rubber Co., Akron, O., has made another advance in production, from 22,000 to 24,000 tires per day.

The Miller Rubber Co., Akron, O., manufacturer of automobile tires, has increased its working schedule to 6,500 tires per day.

The Goodyear Tire & Rubber Co., Akron, O., has made further additions to its working force, and production is now scheduled on a basis of 25,000 tires a day.

Practically all of the rubber-manufacturing plants at Canton, O., have adopted an overtime working schedule. Increases are being made in the number of employees.

IRON AND STEEL—The United Alloy Steel Corp., Canton, O., has increased production at its plant, and is now working on a basis of close to 90 per cent of maximum capacity.

The United States Steel Corp., New York, N. Y., has increased production to an average of about 80 per cent of capacity at its different mills.

The Bethlehem Steel Co., Bethlehem, Pa., has blown in a second blast furnace at its Steelton, Pa., plant; this is the first time that two units have been in service at the mills for a number of months past. The company has resumed operations at another finishing mill at its Lebanon, Pa., plant, giving employment to close to 100 men. Work has also been resumed in the bessemer steel department at the company's plant at Sparrows Point, near Baltimore, which has been idle for a number of months past. About 200 men will be added to the working force at once, and further additions will be made at an early date. It is said that the company is now running at more than 80 per cent of capacity at its different plants.

The Replogle Steel Co., New York, N. Y., is perfecting arrangements for the immediate blowing in of one of the new blast furnaces at its Wharton, N. J., plant. A second unit will be placed in operation at an early date.

The Carnegie Steel Co. has blown in another stack at its Mingo, O., plant, making 30 furnaces in operation at this works. It is planned to resume operations at 5 additional stacks in this district at an early date.

The Central Iron & Coal Co., Tuscaloosa, Ala., has resumed operations at its No. 3 foundry, following a suspension for many months past. About 125 workers have been added to the force and further additions will soon be made.

The Rogers-Brown Ore Co. a subsidiary of the Rogers-Brown Iron Co., Buffalo, N. Y., has resumed operations at its Kennedy properties at Duluth, Minn., which have been closed down since last July.

The Republic Iron & Steel Co., Youngstown, O., will resume operations at once at its iron ore properties at Ironwood, Mich., on a full-time basis.

The LaBelle Iron Works, Steubenville, O., has advanced production to close to 90 per cent of normal capacity.

The Wheeling Steel Corp., Wheeling, W. Va., is increasing production at all of its plants with the exception of the furnace at Martins Ferry, O., and the local steel plant of the Whitaker-Glessner division. It is expected to make advances at the latter works at an early date.

METALS—The Vanadium Steel Alloys Corp. is running full at its Latrobe, Pa., works, with night shift operation in various departments, in addition to regular day production.

The Vanadium Corp. is perfecting arrangements for the early resumption of operations at its plant at Bridgeville, near Pittsburgh, Pa., which has been idle for about a year past.

The East Butte Copper Mining Co., Butte, Mont., will increase production at once at its ore-treating plant. The company has secured a 24-month contract from the Davis-Daly Copper Co., for the treatment of ores from its mines.

The Ray Consolidated Copper Co., Ray, Ariz., is increasing production at its plant, following operations on a curtailed basis since the properties were reopened on April 1.

MISCELLANEOUS—The Santa Cecilia Sugar Co., 115 Broad St., New York, N. Y., is running under increased production at its mills. Up to the present time about 70,000 bags of raw sugar have been made as compared with 59,500 bags for all of last season.

The Wilmington Fibre Specialty Co., Wilmington, Del., has increased the working hours at its plant, with schedule from 7:30 a.m. until 5:30 p.m. Production is being advanced.

Construction and Operation

Arizona

YUMA—The Yuma Valley Cane Sugar Corp. has plans under way for the construction of a new refining plant on local site, estimated to cost in excess of $200,000. Dr. F. Thatcher is president.

AJO—The New Cornelia Mining Co. is having plans prepared for the construction of a new flotation plant at its properties, with capacity of about 10,000 tons. W. R. Weymouth, C. C. Moore Construction Co., Kansas City, Mo., will be in charge of erection.

California

SAN FRANCISCO—W. P. Fuller & Co., 301 Mission St., manufacturer of paints, varnishes, etc., has awarded a contract to R. McLeran & Co., Hearst Bldg., for the construction of a new 5-story addition, estimated to cost about $315,000.

Connecticut

HARTFORD—The Capitol City Glass Co., Chapel St., will soon break ground for the construction of a 2-story addition to its plant, 40x150 ft. F. C. Walz, Hartford, is architect.

STAMFORD—The Charles H. Harris Co., Main St., manufacturer of glass products, has awarded a contract to the Hewlett Co., Bridgeport, Conn., for the construction of a new addition 90x100 ft. Work will be commenced at once.

Illinois

CHICAGO—The National Oxygen Co., 12 East Harrison St., manufacturer of commercial oxygen, has acquired a tract of about one-half acre of land in the Clearing Industrial district for a consideration of approximately $15,000. It will be used for plant expansion.

CHICAGO—The Chicago By-Products Coke Co., 122 South Michigan Ave., has filed plans for the construction of a new building at Crawford Ave. and 35th St., to be used for general service work. The Koppers Co., Pittsburgh, Pa., has the contract for the work.

Indiana

KOKOMO—The Kokomo Gas & Fuel Co. is having plans prepared for the erection of a new artificial gas-manufacturing plant to cost about $500,000, with equipment. The company is affiliated with the Peoples Gas Light & Coke Co., 122 South Michigan Blvd., Chicago, Ill., C. A. Monroe, president. The Koppers Co., Union Arcade Bldg., Pittsburgh, Pa., is engineer for the work.

Kentucky

CATLETTSBURG—The Great Eastern Refining Corp., recently organized, has commenced the construction of its proposed new oil refinery at Leach, near Catlettsburg. The plant will have an initial capacity for handling about 1,000 bbl. of crude oil per day, and it is planned to double this output at a later date. A lubricating oil- and wax-manufacturing plant will also be erected. A. J. Dalton is president.

ASHLAND—The Pittsburgh Brick & Tile Co., Pittsburgh, Pa., represented by Samuel DeBord, Ashland, has acquired a local tract of land and plans for the construction of a new plant for the manufacture of brick, hollow tile and other burned clay products. The initial works will cost in excess of $500,000, including machinery.

Maine

SKOWHEGAN—The Skowhegan Paper Co., Bangor, Me., recently organized with a capital of $200,000, will take over the plant of the Maine Pulp & Paper Co., and plans to resume production at an early date. A number of extensions and improvements will be made. Harold Hinckley is president; and James D. Rice, treasurer.

RUMFORD—The Oxford Paper Co. has awarded a contract to J. W. Kerr, Rumford, for the construction of an addition to its local paper mill, estimated to cost about $40,000. Headquarters of the company are at 200 5th Ave., New York.

Maryland

BALTIMORE—The American Sugar Refining Co., Woodall and Clement Sts., has filed plans for the construction of a 1-story building at its new local plant 107x154 ft. Stone & Webster, Inc., 120 Broadway, New York, is engineer and contractor.

HANCOCK—The Maryland Glass Sand Co. has acquired the plant and business of the Round Top Glass Sand Co., operating in this same district, and will consolidate the works under its present name. Plans are under way for the construction of a number of new additions, and considerable equipment will be installed. The company has increased its capital from $75,000 to $150,000, to provide for the expansion.

Massachusetts

TUFTS COLLEGE—The Board of Trustees, Tufts College, has filed plans for the construction of a new 3-story chemical laboratory, 78x165 ft., on Talbot Ave., estimated to cost about $200,000. The W. H. Whitcomb Construction Co., 6 Beacon St., Boston, is the general contractor.

HOLYOKE—The Palmer Steel Co., recently organized with a capital of $100,000, has acquired property comprising about 14 acres of land at Meadow St. and McKinstry Ave., as a site for its proposed new plant. Plans are under way for the initial buildings, to cost in excess of $500,000. Wayne F. Palmer, 7 Montgomery Ave. is treasurer.

Minnesota

ST. PAUL—The St. Paul Brass Foundry Co., 288 Minnesota St., is considering plans for the construction of a new 1-story plant addition, 36x50 ft., to be equipped for the manufacture of brass and bronze castings, etc. Frederick Oshrlein, president, is in charge.

Missouri

TRENTON—The City Council is having plans prepared for the construction of a new filtration plant, in connection with extensions and improvements in the waterworks system, estimated to cost about $180,000. Burns & McDonnell, 402 Interstate Bldg., Kansas City, Mo., are engineers.

CEDAR CITY—The Standard Crate & Filler Co., Jefferson City, Mo., is perfecting arrangements for the erection of its proposed new local mill for the manufacture of strawboard products. The company recently purchased a site. The new plant will cost close to $350,000, and will have an initial daily capacity of about 150 tons. A. W. Happy is president.

New Jersey

MAURER—Fire, May 16, destroyed a portion of the plant of the United Lead Co.,

111 Broadway, New York, N. Y., at Maurer, near Perth Amboy, with loss estimated in excess of $1,200,000, including stacks, buildings, machinery, etc.

BAYONNE—The Standard Oil Co. of New Jersey, 25 Broadway, N. Y., has plans nearing completion for the construction of a new 1-story oil separating plant, 60x200 ft., at its Constable Hook refining works. Tucker & Lewis, 103 Park Ave., New York, are engineers.

NEWARK—Fire, May 11, destroyed two buildings at the plant of the Alcohol Products Co., Blanchard St. and the Passaic River, with loss estimated at about $200,000, including equipment. Henry W. Miner is president.

NEWARK—The Magna Metal Corp., Doremus Ave., Port Newark district, manufacturer of special metals, operating at the former plant of the Atlantic Smelting & Refining Co., has tentative plans under consideration for the erection of an addition.

PERTH AMBOY—The Perth Amboy Gas Light Co., 196 Smith St., has plans under way for extensions and improvements in its artificial gas plant, including the erection of a new holder with capacity of about 1,000,000 cu.ft.

BAYONNE—Fire, May 16, destroyed a portion of the plant of the Tidewater Oil Co., 11 Broadway, New York, N. Y., with loss totaling close to $700,000, in tanks and other equipment, stock, etc.

GLASSBORO—The New Jersey Corp. has been organized by bondholders of the former New Jersey Gas Co., and has taken over the artificial gas plant and system of the latter company. Improvements will be made and the plant continued in operation. The new company is capitalized at $1,690,000. Norman Grey is president.

New York

SILVER SPRINGS—The Worcester Salt Co., 71 Murray St., New York, has commenced the erection of a new local manufacturing plant, to be 2-story, 42x148 ft. The John W. Ferguson Co., United Bank Bldg., Paterson, N. J., is the contractor.

COHOES—The Frank Gilbert Paper Co., 135 Broadway, New York, a division of the Hercules Paper Corp., same address, is reported to be planning for the erection of an addition to its local mill to cost approximately $50,000. Fire, May 5, destroyed the old pulp mill of the company, with loss estimated in excess of $25,000, including machinery, etc.

PORT HENRY—Witherbee, Sherman & Co., 2 Rector St., New York, have plans under way for the construction of a new blast furnace, in the vicinity of their present furnace, with daily capacity of 500 tons of pig iron. The works will include a sintering plant with daily output of 400 tons; electrically operated pumping plant; laboratory, warehouse and other structures. The installation will comprise two blowing engines, rated at 45,000 cu.ft. capacity each, 65,000-hp., boilers, and other equipment. The plant is estimated to cost about $2,000,000. To provide for the construction, the company has disposed of a bond issue of $4,000,000. Lewis W. Francis is president.

NEW YORK—The Corn Products Refining Co., 17 Battery Place, has organized a subsidiary company with capital of $1,000,000, to operate in Germany. Three refining plants now established in that country will be acquired and plans are being considered for the erection of a fourth refinery on site to be selected. G. M. Moffet, vice-president of the parent company and official of the new organization, has left for Germany to perfect the plans for the project. J. W. Fisher and George Mahana, directors of the Corn Products Company, will be active in the German subsidiary.

NEW YORK—The Crystal Chemical Co., 130-34 Willis Ave., has filed plans for improvements and alterations in its plant to cost about $10,000.

North Carolina

MARION—The Clinchfield Pottery Works is planning for enlargements in its plant for increased output. A. W. Hilton is president.

Ohio

BELLAIRE—The Standard Slag Co., 707 Wick Bldg., Youngstown, O., will build a new 4-story plant at Bellaire, 40x75 ft., with crushing, grinding and other producing departments.

WOOSTER—The Weldless Tube Co., recently organized with a capital of $300,000, has acquired a site of about 100 acres of land near the city, and has preliminary plans under way for the construction of a new tube mill, estimated to cost in excess of $100,000.

Oklahoma

WAYNOKA—The Oklahoma Pure Salt Co. has preliminary plans under way for the construction of a new plant, to utilize salt deposits in Harper and Woodward counties.

MANGUM—The Chamber of Commerce is developing plans for the establishment of a local gas plant. It is proposed to organize a company to operate the works.

VINITA—The City Council has plans under way for the installation of a new filtration plant in connection with extensions and improvements in the water works. Burns & McDonnell, 402 Interstate Bldg., Kansas City, Mo., are engineers.

Pennsylvania

ROCHESTER—The American Borax Co. has acquired a portion of the former Keystone plant of the National Glass Co., and will remodel the structure for a new works. Plans are under way for the construction of a new 3-story plant, estimated to cost about $150,000, including machinery.

READING—The Reading Casting Co., 1432 Mulberry St., manufacturer of iron and steel castings, is said to have preliminary plans under way for the rebuilding of the portion of its plant destroyed by fire May 12, with loss estimated at about $50,000, including machinery.

PHILADELPHIA—The Shingle Leather Co., 315 Vine St., has awarded a contract to the Bowden Construction Co., 1713 Sansom St., for the construction of its proposed 1-story plant at 54th St. and Grays Ferry Ave., to be 120x195 ft., and estimated to cost about $50,000. Carson & Carson, Franklin Trust Bldg., are engineers.

PHILADELPHIA—The Henry Bower Chemical Mfg. Co., 29th St. and Grays Ferry Ave., has had plans prepared for the construction of an addition to its plant. Bissell & Sinkler, Otis Bldg., are architects.

PITTSBURGH—The Pittsburgh Steel Co., Union Arcade Bldg., has tentative plans under way for the construction of an addition to its plant at Wireton, Pa. Willis F. M. Cook is president.

Tennessee

COPPERHILL—The Tennessee Copper Co., 61 Broadway, New York, N. Y., is reported to be planning for extensions and improvements in its local plant, to cost about $200,000, including equipment. It is proposed to construct a new flotation plant at a later date.

Texas

PASADENA—The Great Lakes Western Refining Co. has acquired the local plant of the Port Houston Refining Co., with capacity of about 325 bbl. of oil per day. The company will operate the refinery and has plans under way for the construction of additional units to provide an output close to 1,500 bbl. per day. J. C. Carrington is head.

ODESSA—The Farmers Oil Co., Inc., Woolworth Bldg., Lancaster, Pa., has acquired property aggregating about 75,000 acres in the Odessa field, with oil, gas and potash deposits, and plans for extensive operations on the tract. Plans are said to be under way for the early erection of a large potash plant. H. A. Hartzell is president.

Virginia

WEST POINT—The Chesapeake Corp. has plans in preparation for the construction of an addition to its plant for the manufacture of paper products and pulp board, etc. It will cost about $250,000, of which amount approximately $100,000 will be expended for equipment. W. C. Gouldman is secretary.

PETERSBURG—The Southern Chemical Co. is having plans prepared for the construction of a new plant on local site. Work will be commenced at an early date.

Washington

BEVERLY PARK—The Orient Rubber Co., recently organized with a capital of $500,000, will soon break ground for the construction of a plant for the manufacture of rubber goods, under a special reclaiming process. The company is headed by H. H. Hazelton and J. H. Brokow.

West Virginia

HUNTINGTON—The Huntington Products Co. has acquired the local plant of the Glass Brick Co., manufacturer of slag brick and kindred products, and will place the plant in service at once, to develop an output of about 50,000 bricks per day. Plans are said to be under way for plant expansion. H. B. Jackson is president and general manager.

Wyoming

CASPER—The Texas Co., 17 Battery Place, New York, N. Y., has preliminary plans under way for the construction of a new oil refinery on local site, with initial capacity to handle about 5,000 bbl. of crude oil per day from the Salt Creek field. It is proposed to commence the work early in the summer.

New Companies

THE QUALITY BRANDS CO., New York, N. Y., has been incorporated with a capital of $75,000, to manufacture paints, greases, oils and kindred products. The incorporators are A. and E. Lehman, and R. Whitney. The company is represented by Harry Kutscher, 50 Broad St., New York.

THE MERRIMACK CLAY PRODUCTS CO., Boston, Mass., has been incorporated with a capital of $400,000, to manufacture brick, tile and other burned clay products. M. Kimball Wentworth is president; and M. A. McGrath, 38 Newbury St., Newton Centre, Mass., treasurer.

THE LYNCHBURG PIGMENTS CORP., Lynchburg, Va., has been incorporated with a capital of $25,000, to manufacture paints and kindred products. John A. Weinman is president; and William A. Robertson, secretary, both of Lynchburg.

THE NITRO POWDER CORP., Jersey City, N. J., has been incorporated with a capital of 100 shares of stock, no par value, to manufacture chemicals and chemical byproducts. The incorporators are George V. Reilly, Harry C. Hand and A. Roy Myers. The company is represented by the United States Corporation Co., 15 Exchange Place, Jersey City.

THE ENNIS PETROLEUM PRODUCTS CO., 208 South La Salle St., Chicago, Ill., has been incorporated with a capital of $25,000, to manufacture oil specialties. The incorporators are Edward C. Ennis, Charles A. Dunn and Edward R. Tiedebohl.

THE GORDEE PRODUCTS CO., Wilmington, Del., has been incorporated under state laws with a capital of $200,000, to manufacture chemicals and chemical byproducts. The company is represented by the Corporation Service Co., Equitable Bldg., Wilmington.

THE RELIANCE FOUNDRY CO., Cincinnati, O., has been incorporated with a capital of $50,000, to manufacture iron, steel and other metal castings. The incorporators are Charles Radley and Edwin D. Brooks, both of Cincinnati.

THE JERSEY CITY ENAMELING & REFINING CO., 307 Ocean Ave., Jersey City, N. J., has filed notice of organization to manufacture enamels and kindred products. The company is headed by William Lehndorff and Peter Connin, 197 Linden Ave. Jersey City.

THE BYBEE POTTERY CO., Frankfort, Ky., has been incorporated with a capital of $15,000, to manufacture pottery goods of various kinds. The company has plans under way for the establishment of a local plant. The incorporators are William J. Jillison, Joseph W. Porter and Bullitt McCoun, all of Lexington, Ky.

THE UNITED MAGMA COPPER CO., Wilmington, Del., has been incorporated with a capital of $3,500,000, under state laws, to manufacture refined copper and other metals. The company is represented by the Delaware Corporation Co., Ford Bldg., Wilmington.

THE UNITED STATES FIBER LATH & PLASTER BOARD CO., 4425 Filmore Ave., Chicago, Ill., has been incorporated with a capital of $10,000, to manufacture fiber composition products. The incorporators are C. Earnest Guyton, Noble E. Snyder and William R. T. Ewen.

THE MILLER-LISZKA CORP., New York, N. Y., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are O. W. Swift, J. C. Williams and F. W. Kristeller. The company is represented by Watson, Kristeller & Swift, 68 William St., New York.

THE STANDARD OIL CO. OF FLORIDA, St. Petersburg, Fla., has been incorporated with a capital of $1,000,000, to manufacture petroleum products. The incorporators are C. W. Beck, St. Louis, Mo.; R. F. Beck, Webster Grove, Mo.; and R. V. Sellers, St. Petersburg.

THE ENTOMOLOGICAL LABORATORIES OF NORTH AMERICA, INC., Jersey City, N. J., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts, insect destroyers, etc. The incorporators are Albert H. Mitschele and Albert Stehling, 71-A Poplar St., Jersey City.

THE BELMENBY CO., Wilmington, Del., has been incorporated with a capital of $200,000, under state laws, to manufacture cottonseed oil products. The company is represented by the Corporation Service Co., Equitable Bldg., Wilmington.

THE PECOS PETROLEUM CO., 30 North La Salle St., Chicago, Ill., has been incorporated with a capital of $300,000, to manufacture petroleum products. The incorporators are E. M. Nadel, Kenneth M. Rogan and William E. Bell.

THE SUPERIOR CHEMICAL CORP., St. Louis, Mo., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are William Ross, Carr L. Glasgow and H. G. Bristow, all of St. Louis.

THE PUNCTURE SEAL MFG. CO., Seattle, Wash., has been incorporated with a capital of $50,000, to manufacture liquid compounds, chemicals, etc. The incorporators are William M. Orthan, A. E. Shrimpf and G. M. Watson, all of Seattle.

THE SUPERIOR TANNING CO., 1254 West Division St., Chicago, Ill., has been incorporated with a capital of $150,000, to manufacture leather products. The incorporators are Samuel, Henry and Mayer Katz.

THE REPUBLIC METAL ALLOYS CORP., New York, N. Y., has been incorporated with a capital of $25,000, to manufacture metal alloys. The incorporators are M. J. Brownstein, E. Friedman and D. Wachstock. The company is represented by M. M. Helfgot, 35 Nassau St., New York.

THE IDEAL COLORINE CO., 17 Seymour Ave., Newark, N. J., has filed notice of organization to manufacture coloring specialties, chemicals and chemical byproducts, etc. The company is represented by Samuel Granet.

THE CHELSEA REFINING CO., Tulsa, Okla., has been incorporated with a capital of $1,000,000, to manufacture refined oil products. The incorporators are W. M. Welch, W. L. Walker and D. W. Bell, all of Tulsa.

THE GRIBURN CO., Philadelphia, Pa., has been incorporated under Delaware laws with a capital of $100,000, to manufacture chemical products, disinfectants, etc. The company is represented by the Corporation Guarantee & Trust Co., Land Title Bldg., Philadelphia.

THE CEASAR RESILIENT TIRE CORP., New York, N. Y., has been incorporated with a capital of $200,000, to manufacture automobile tires and other rubber products. The incorporators are P. Di Ceasar and C Capria. The company is represented by F. J. Rinaldi, 167 East 121st St., New York.

THE PINE PRODUCTS CORP., Camden, N. J., has been incorporated with a capital of $100,000, to manufacture pine tar products and affiliated specialties. The incorporators are Henry W. A. Hanson, Norman H. Schich and Hamilton Turner. The company is represented by Oscar B. Redrow, 428 Market St., Camden.

THE RUSSELL PAINT CORP., Pittsburgh, Pa., has been incorporated under Delaware laws with capital of $100,000, to manufacture paints, varnishes, etc. The incorporators are George J. Young, H. T. Germann and Charles L. King, all of Pittsburgh. The company is represented by the Capital Trust Co. of Delaware, Dover, Del.

THE SUPERIOR LEATHER CO., 2610 North Western Ave., Chicago, Ill., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture leather products. The incorporators are W. S. Shaw, E. F. Shaw and R. C. Tallcott.

THE MAR-VEL-O MFG. CORP., New York, N. Y., has been incorporated under Delaware laws with capital of $250,000, to manufacture chemical products, washing fluids, etc. The incorporators are John T. McGovern, M. E. Nolan and M. E. Brause, all of New York. The company is represented by the Delaware Registration & Incorporators Co., Ford Bldg., Wilmington, Del.

L. DE LONG & BROTHER, INC., Newark, N. J., has been incorporated with a capital of $100,000, to operate a metal smelting and refining plant. The incorporators are G. Lawrence Feldman, Jr., Albert A. Schmidt and Louis De Long, 345 Halsey St., Newark.

THE CONSOLIDATED INK CO., New York, N. Y., has been incorporated with a capital of $40,000, to manufacture inks and kindred products. The incorporators are C. A. Johnson, J. R. Norwood and H. Fixler. The company is represented by Barnes, Chilvers & Halsted, 2 Rector St., New York.

Capital Increases, etc.

THE BEACH CHEMICAL CO., St. Louis, Mo., has filed notice of increase in capital from $100,000 to $200,000.

THE ROGERS-BROWN IRON CO., Buffalo, N. Y., producer of pig iron, coke, ferromanganese, etc., has filed notice of increase in capital from $7,000,000 to $8,000,000.

THE VALVOLINE OIL CO., 60 Broadway, New York, N. Y., has arranged for a bond issue of $2,000,000, to be used for general operations, additions to working capital, etc. The company is operating oil refineries at Warren and East Butler, Pa., and Edgewater, N. J.

THE PORTSMOUTH GAS CO., Portsmouth, Va., has arranged for an increase in capital from $500,000 to $1,000,000, a portion of the proceeds to be used for extensions and improvements in its artificial gas plant. B. B. Ferguson is president.

THE BLACK SILK STOVE POLISH WORKS, Sterling, Ill., manufacturer of polishes, etc., has filed notice of increase in capital from $25,000 to $150,000.

THE FRANCISCO SUGAR CO., 112 Wall St., New York, N. Y., operating a refinery in the Province of Camaguey, eastern part of the Island of Cuba, is disposing of a bond issue of $5,000,000, a portion of the proceeds to be used for general expansion, operations, etc. Manuel Rionda is president.

THE BEACON OIL CO., 111 Devonshire St., Boston, Mass., has disposed of a preferred stock issue of $1,500,000, the proceeds to be used for expansion.

THE VITREOUS ENAMELING & STAMPING CO., 1381 Sedgwick Ave., New York, N. Y., has filed a petition in bankruptcy, showing liabilities of $212,588 and assets of $137,350.

THE AMALGAMATED SUGAR CO., Ogden, Utah, is arranging for a bond issue of $4,000,000, the proceeds to be used for general expansion, operations, etc.

THE PENTEX OIL CO., Philadelphia, Pa., John E. Cupp, 731 Land Title Bldg., representative, has filed notice of dissolution under state laws.

THE PARAMET CHEMICAL CORP., Lexington Ave. and 131st St., New York, N. Y., manufacturer of chemicals and chemical byproducts, has made an assignment to James F. Gilkinson, 67 Wall St., New York.

THE SAMSON FIREPROOF BLOCK CORP., New York, N. Y., has been incorporated with a capital of $8,000, to manufacture refractory products. The incorporators are V. I. Weedon, W. S. McKay and C. M. O'Neill. The company is represented by S. F. Hartman, 120 Broadway, New York.

THE CELLUFIBRE CORP., New York, N. Y., has been incorporated under Delaware laws, with a capital of $4,100,000, to manufacture celluloid products. The incorporators are Robert A. MacLean and James L. Watson, New York; and F. H. Butehorn, Brooklyn, N. Y. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del.

THE OKAMO OIL CORP., Geary, Okla., has been incorporated with a capital of $25,000, to manufacture petroleum products. The incorporators are A. W. Green, W. D. Priddy and H. E. Castleberry, all of Geary.

THE ASSOCIATED FERTILIZER MANUFACTURERS OF AMERICA, INC., Trenton, N. J., has been incorporated with a capital of $250,000, to manufacture fertilizer products. The incorporators are William G. Hopper, Raymond Hutchinson and Kenneth H. Lanning. The company is represented by Wicoff & Lanning, 705 Broad St. Bank Bldg., Trenton.

THE INTERSTATE STEEL PRODUCTS CO., Indianapolis, Ind., has been incorporated with a capital of $100,000, to manufacture steel specialties. The incorporators are Murat Hopkins, Chester H. Ricker and Robert Tafel, all of Indianapolis.

W. A. DOYLE & CO., INC., New York, N. Y., has been incorporated with a capital of $50,000, to manufacture cleaning powders, chemicals, etc. The Incorporators are R. B. and W. A. Doyle, and R. B. Rainder. The company is represented by Campbell & Boland, 342 Madison Avenue, New York.

THE HARRIS PETROLEUM CO., Dover, Del., has been incorporated under state laws, with a capital of $800,000, to manufacture petroleum products. The company is represented by the United States Corporation Co., 65 Cedar St., New York, N. Y.

THE BARNETT TANNING CO., New York, N. Y., has been incorporated with a capital of $10,000, to manufacture leather products. The incorporators are M. and H. S Barnett. The company is represented by H. E. Cohen, 115 Broadway, New York.

THE MIDLAND SPECIALTIES CO., 2510 Wallace St., Chicago, Ill., has been incorporated with a capital of $15,000, to manufacture sheet steel products. The company is represented by T. P. Grant, Room 1005, 56 West Randolph St., Chicago.

THE NEUCES OIL CO., Tulsa, Okla., has been incorporated with a capital of $25,000, to manufacture petroleum products. The incorporators are O. S. Booth, Rex S. Walker and H. G. Dickenson, all of Tulsa.

THE NELSON MOTOR FUEL & FERTILIZER CO., Tampa, Fla., has been incorporated under Delaware laws, with capital of $100,000, to manufacture refined oils, fertilizers, etc. The incorporators are O. W. Nelson, Herbert M. Banker and Paul S. Maxwell. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold a joint meeting with the Pacific Division of the Association, on the occasion of the annual meeting of the latter, in Salt Lake City, June 22 to 24.

AMERICAN ASSOCIATION OF ENGINEERS will hold its eighth annual convention at Salt Lake City, Utah, June 4-6.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Pittsburgh, Pa., Sept. 5 to 9.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 21, 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, Canada, June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its nineteenth annual meet- at Bigwin Inn, Bigwin Island, in the Lake of Bays district, Ontario, Canada, on June 21, 22 and 23.

AMERICAN OIL CHEMISTS' SOCIETY will hold its annual meeting at the Grunewald Hotel, New Orleans, La., June 5 and 6.

AMERICAN PULP AND PAPER MILL SUPERINTENDENTS ASSOCIATION will meet in Kalamazoo, Mich., June 1, 2 and 3.

AMERICAN SOCIETY FOR STEEL TREATING will hold a sectional meeting at the Bureau of Mines auditorium, Pittsburgh, Pa., on May 25 and 26. The International Steel Exposition and Convention of the society will be held in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

ANNUAL SAFETY CONGRESS OF THE NATIONAL SAFETY COUNCIL will be held in Detroit, Mich., Aug. 28-Sept. 2.

CERAMIC SOCIETY (London) is to have a foreign trip to Sweden and Denmark from May 27 to June 10.

CHEMICAL SALESMEN'S ASSOCIATION, New York Chapter, will hold the next meeting on May 25 at the Advertising Club.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

NATIONAL COAL ASSOCIATION will hold its annual meeting at Congress Hall, Chicago, May 24-25.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NATIONAL FERTILIZER ASSOCIATION will hold its twenty-ninth annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 12.

NATIONAL LIME ASSOCIATION will hold its annual convention June 14-16 at the Hotel Statler, Cleveland, O.

NEW JERSEY CHEMICAL SOCIETY will meet at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meeting is scheduled to be held in Rumford Hall, the Chemists' Club, New York: June 9—American Chemical Society, regular meeting.

When Does an Employment Contract Terminate?

THE discussion on this subject, which has appeared from time to time in these pages, has been of much interest and value. There can be no doubt that there exists some dissatisfaction over contracts offered technical men and the suspicion seems not ill founded that there may be some injustice in them. It is, therefore, not undesirable perhaps to summarize the situation and endeavor to arrive at some fair and constructive conclusion.

First, from the standpoint of the technical man there appears to be agreement that there is a vagueness about the average contract offered technical men which opens the door to misunderstandings. These misunderstandings apparently are due for the most part to the technical man's ignorance of his own right. He may be considered partly to blame for this, but the system under which he is trained is certainly more to blame than the individual himself. The most important right to him is his right to be recompensed for discoveries made while working on a salary, through his ownership of shop rights in discoveries which he has made. Under present practice he is very apt to sign away these rights in a contract which is perfectly valid. If, now, the knowledge of these inherent rights were a matter of general comprehension, it would be unlikely that an employing corporation would embody in the contract such usurious exactions as a price of employment. That there exists a suspicion on the part of the employee that he is the victim of an unavoidable and unfair condition is a well-established fact. How much better it would be for all concerned if the technical man were promised a fair return for discoveries which he might make while in the employ of the company.

The second cause for considerable dissatisfaction among technical men is the curtailment of their field of usefulness outside of the employer's factory walls. It has been decided legally that such restriction is unenforceable and the knowledge of such decision is fairly widespread among technical men. The insertion of such clauses in an employment contract is usually intended to intimidate the technical man and in so far as they have a deterrent action upon dishonest employees, they have fulfilled their function.

There seems also to be a complete unanimity as to the employer's duty and privilege to protect his property rights. These property rights would seem to include all the knowledge which he possessed up to the time of the employee's engagement and all other knowledge gained during the employee's stay which was not developed by that particular employee himself. The great difficulty seems to be as to how much property right the employer has over uninvented things that the employee may contribute in the future while working under a salary. The consensus seems to be that no man should be asked to sign away an interest in an invention not yet made and that perfect justice would give the employee some personal share in the work of its success.

The whole situation actually rests with the employer. With technical men as a class, it can be said with considerable confidence that in so far as they are trusted and in so far as their own aims and aspirations are made coincident with those of the employer, just so far will the employer enlist their loyalty. No employer has the logical or actual right to demand loyalty from an employee when he demands service which not only does not develop, but actually cramps and hinders the employee's career. We doubt if legislation would be of assistance, for unless the relationship is above any legal plane it ceases to be desirable either to the employer or the employee. We do believe, however, that teachers of chemistry and chemical engineering can make a distinct contribution toward remedying the situation by arranging with competent counsel for one or two lectures a year on the elements of contractual relations.

Discredited Among His Colleagues

SENATOR KING undertook to break down the dye industry of this country by one of the most vitriolic attacks which has ever been made in any Congress upon any young and growing branch of business. He charged monopoly. He charged everything else which might discredit the industry in the eyes of the public. Backed by statistics which contained just sufficient truth to be believable by many, he urged and finally obtained authorization for a Senate investigation. Thanks to Senator FREYLINGHUYSEN, this investigation was made to cover not only the producer but also the importer of dyes. And now the investigation has virtually reached its end.

As a result of the very comprehensive proceedings under the able chairmanship of Senator SHORTRIDGE, it has been conclusively demonstrated that Senator KING'S charge of monopoly is simply bunk. He and the various witnesses from all quarters have conclusively proved that there are in the industry several very large companies. That is all that has even been seriously charged by any one appearing before the committee. Even the most vigorous opponents of an embargo for the domestic dye producers have been forced to deny that there is anything approaching monopoly.

But incidentally the investigation has demonstrated another thing. It has most convincingly set before the members of the Senate the real situation with reference to the organic chemical industries of the United States. The investigation can, in fact, be credited with having convinced the Finance Committee of the Senate that an extension of the embargo on dye importation was desirable. It seems to be unquestioned that it was the

proceedings which started as an attack upon the industry that ultimately proved a tremendous blessing in this particular.

As things now stand, we cannot know for some time what the Shortridge committee has concluded or will recommend to the Senate. The chairman of the committee and the other members of the Senate interested have, however, said enough so that it may be safely forecast that the conclusions and recommendations will be in general favorable and beneficial to the American dye producer.

The industry has come through with a clean, fine record. It is going to be given a slightly extended period of protection against unrestricted import. For at least one year, and more likely two years, after the passage of the pending tariff bill (assuming that that bill ever does pass), a license for imports will be required. What may happen after that no one now can forecast. But there still remains a considerable period in which to set in order the defenses of this industry to meet any mass attack through importation.

The most effective defense against that attack will be the result of research applied as improved technology. If there ever has been a time in any chemical industry when research was needed, it is now in the dye industry. Through research and its application to processes and products, the industry may hope permanently to meet any foreign competitor. American inventive genius, American methods of economical mass production, and clean-cut, vigorous American business methods can well expect this success if they are builded upon sound science and the best possible technology. However, without that foundation none, nor even all of them, can succeed.

Steel Makers Dine With the President

SOME of the commonest things today were quite novel when introduced. The nothing-new-under-the-sun dictum must be adopted with reservations. The first umbrella was a startling innovation and there was even a time when clothes were not worn.

It is a new thing for the President of the United States to invite representative members of the steel industry to dine with him, yet it is not difficult to conceive of such contacts becoming common. Why should not the head of the nation talk frankly with groups of men who have much to do with the course of everyday affairs in the country?

The news dispatches from Washington told of President HARDING having at dinner with him on the 18th twoscore or more of representative steel manufacturers, to discuss informally the subject of the 12-hour day in the iron and steel industry. The dispatches did not bring out the naturalness of the thing, possibly because it is unnatural for newspaper men to seek to minimize the novelty of what they report. But when the head of a large corporation finds in his reports something that he thinks can be improved upon, he is likely to call a conference of those involved. Now the fact is that the Department of Labor has in press at the present time a new report on "Hours of Labor in the Iron and Steel Industry." The report, according to the statement released for the press a week ago, "shows that a considerable change was made in the hours of labor of employees between 1910 and October, 1920, the date of the last figures in the report." It seems like rather a belated report, of course, but probably it was only recently placed before the President. So it is not strange that Mr. HARDING, seeing the report, might conceive the idea of inviting some of the men who have to do with this matter to dine with him and go over the ground. In ten years progress had been made in reducing the proportion of 12-hour employment, why not see if the progress could not be stimulated?

Business men of the United States are anxious to be in real contact with the government. The saying "Less government in business, more business in government" is not contradictory. The difference is between natural contact and the uncomfortable contact that comes from impact. The steel industry itself furnishes a good illustration. The U. S. Steel Corporation was formed in the spring of 1901. In 1908, testifying before the Stanley committee, Judge GARY, chairman of the Steel Corporation from the outset, said plainly and earnestly that he would welcome an arrangement whereby the Steel Corporation would lay all its information before the government and the government would then tell it what it should do and what it should not do. Three years afterward, more than ten years after the corporation had been formed, the government brought suit against it for dissolution. By a Supreme Court decision of four to three the Steel Corporation survived the impact, but it was not the kind of contact that has been found good in the conduct of business.

The Constitution of the United States, by the way, requires the President to inform Congress from time to time as to the state of the Union. Some Presidents have used many thousands of words in telling about government departments rather than the state of the country. In inviting groups of men to dine with him the President is seeking just such information as he ought to have.

Along This Road Lies Profit

HENRY FORD states in his autobiography—now being published in *McClure's Magazine*—that the way to profit in automotive manufacture is first to settle definitely on the design of the motorcar and then devote all possible effort to improving the equipment and methods by which it is produced, rather than to endeavor to change the design and bring out a "new" model from time to time. The success which he has attained by following these methods has been so conspicuous that it would not seem possible to arouse much opposition to the statement. Nevertheless, many do not seem to accept this as true and prefer to look to luck or some other intangible factor as the touchstone of FORD'S success.

If we change the above to fit the chemical industries, it would read something like this: The way to profit from chemical manufacture is to settle definitely on the process to be used and then to devote all possible effort to improving the machinery and methods by which this process is accomplished. This is, unfortunately, even less an accepted maxim of chemical manufacture than it is of automotive industry. The actual method more often followed seems to be, rather, to go on with a manufacturing process in exactly its original form until someone invents a new process or a better product as a substitute and, by the advantage thus gained, eventually forces everyone concerned to adopt the new way.

Our suggestion is in no way to be taken as con-

demnation of scientific research, which is essential to progress in industry. Rather is it a plea that some of the research be directed to developing better equipment for already established processes and finding better ways of operating and managing them. To do this may curtail to some extent the amount available to be spent in research along new lines, but from both the social and business viewpoints we feel that it is perhaps better that the cause of science should suffer temporarily until money is available for full efforts along both lines. This is because the road traveled toward perfection in equipment and method also leads us to far better working conditions for the employee and, for the employer, to the goal of all endeavor—increased profits.

Sulphur and Manganese In Rivet Steel

"HIGH SULPHUR" has long been one of the accepted excuses for baffling defects; sulphur has universally been condemned as an ingredient in steel.

And yet after a careful search in literature we were unable to find any metallurgist placing a definite limit on sulphur for any particular class of steel and giving anything like a clear idea of what would happen if the danger line was overstepped. Steels made before the advent of chemical specifications wore out after long and honorable service before they were discovered to be "dangerously high" in sulphur. In more recent and scientific years chemical specifications for sulphur in steel have varied geographically to a certain extent. The Swedes insist on very low sulphur; the English are much more tolerant; the Americans occupy a middle ground. One almost suspected that a piece of steel if it were honestly and skillfully made would not be spoiled for ordinary uses in rails, shapes or plates by any reasonable amount of sulphur. Perhaps sulphur has been taking the blame all these years because it can be determined chemically, while dissolved gases cannot. Perhaps, too, the excess manganese demanded to "neutralize the sulphur" also did unnoticed yeoman service in neutralizing the oxygen.

But now we have some real information on the subject! An important report on the "Effect of Sulphur on Rivet Steel" has been issued, containing the first data issued since the Joint Committee commenced its work, two years ago. It contains, in graphical form, the results of an exhaustive series of thousands of tests on several selected steels, held as constant in chemical composition as possible except as to sulphur. Apparently here are the data necessary for judging and condemning the culprit—but for reasons of its own, the committee has abstained from any comment on the significance of the tests, leaving each interested engineer to draw his own conclusions. This has been done by one of the editors of CHEM. & MET. for his own edification and perhaps for that of others, as set forth on page 1019 of this issue.

One is tempted to speculate upon the reasons why the committee, which undoubtedly is best qualified to interpret the results, did not state in words the plain indication of the tests. Primarily, the investigation was undertaken to determine whether the war-time specifications permitting high sulphur could be safely retained. Well, can they?

Perhaps the committee declined to say yes or no to such a direct question because it has found that this monumental investigation has tested more than the effect of sulphur in steel. Primarily it has tested our methods of testing—not only their competence but their significance. It has raised such questions as this: What standardized test will give the same indications that can be had from pulling a joint apart, breaking tightly stretched rivets by combined crushing, bending and shear? This question of *competence* of test should seemingly have been decided long ago. Else why spend so much time testing slabs in torsion, for instance? From the published curves, shearing tests on a plain bar are found to parallel strengths of riveted joints admirably, the good old ultimate strength in tension is a close second.

Again, what impact test shall we use? Impact shear on rivet bars in the annealed state are approximately the same as when received from the mill, while Charpy values for annealed bars are cut down 80 per cent. Shall we accept the impact shear, or the Charpy results? Furthermore, it appears to be immaterial whether an unnotched specimen is broken with or across the direction of rolling—the work expended is substantially the same. It may be debatable whether the result of the impact tests on unnotched specimens denotes a uniform material or an insensitive testing method. It might even be that the impact shear is sensitive and accurate, and the material is uniform. Must we then conclude that both the Izod and Charpy are capricious?

Assuming, however, that all these tests are competent and significant, an inspection will show that high sulphur has surprisingly little effect. Twenty of the graphs, if approximated by a median line sketched freely, actually show well-defined maxima or minima at 0.04 to 0.05 per cent sulphur. This might support the contention of certain manufacturers that it is more damaging to "force" open-hearth heat for extremely low sulphur than to leave it in, were it not for the fact that the manganese curve shows a definite minimum in the same region. In fact one or two of the most jagged curves presented by the committee are less baffling if plotted against manganese! While it would be unfair to suggest that the committee has tested the effect of manganese rather than sulphur, these facts, and the rather wide range of manganese contents, make it certain that the results have actually tested the effect of *sulphur plus manganese* on rivet steel.

Some interesting sidelights appear. An unexpected heat containing 0.18 per cent sulphur suggests that the whole art of open-hearth steel melting has been tested. Furthermore, the comparatively innocuous effect of such dangerously high sulphur has tested one of our cherished metallurgical prejudices. Finally, the heat-treatment of low-carbon steel is before the court, for certainly a correct anneal would not be expected to damage the impact properties so greatly.

Perhaps the Joint Committee may be pardoned for not opening this Pandora's box, but it seems that one conclusion will unavoidably be reached from a study of the published tests, and that is this:

In well-made basic open-hearth steel containing less than 0.02 per cent phosphorus, approximately 0.11 per cent carbon and 0.43 per cent manganese, the maximum sulphur now allowed in rivets for structural steel (0.045 per cent) is at least 0.01 per cent below the quantity where sulphur will damage the strength, at least as far as its performance can be predicted by known tests.

Readers' Views and Comments

Radium Production in America*

To the Editor of Chemical & Metallurgical Engineering

SIR:—In two recent papers of this title by H. D. d'Aguiar,[1] the recovery, refining and measurement of radium from carnotite ore were outlined. While Mr. d'Aguiar does not mention the company employing the practice described, the writer is informed that it was that of the former Radium Luminous Materials Corporation, of Orange, N. J.

It is very gratifying that one of the leading radium companies is willing to give its flow sheet and describe its operations. The radium industry in this country has, in some instances, suffered greatly in the past from the lack of proper technical advice and control. This has been particularly true of companies just beginning to operate. In fact, many operations both early and recent have failed from no other cause than this. There is far less excuse today for such a condition prevailing than 10 years ago. The number of technical men familiar with radium measurements and competent to direct plant operations has increased many-fold in that period. The writer, therefore, welcomes information of the character that Mr. d'Aguiar has presented and believes it will be of benefit to the radium industry. Additional value would have been given to Mr. d'Aguiar's paper had he presented more data in regard to recoveries and costs. Any process, chemical or otherwise, must stand or fall on the efficiency and economy of its operation. The writer will take the liberty of making a few comments on some of the points raised by Mr. d'Aguiar, and also of pointing out features of the process described where additional information would be very welcome.

Mr. d'Aguiar makes the statement that the radium-uranium ratio in carnotite may be altered by contact with water, even by such contact as would be brought about by not keeping the ore entirely dry during storage. While it is not intended to challenge this statement flatly, the writer desires to point out that it is not in accordance with the generally accepted results of dry and wet concentration methods as applied to carnotite. Some experiments on both the wet and dry concentration methods, by the Bureau of Mines a number of years ago, indicated that no change is produced in the radium-uranium ratio. Since that time wet mechanical concentration has been much more extensively employed and additional information on this point by the operating companies would be very valuable.

Mr. d'Aguiar describes the application of the alpha ray method in checking the analytical results for U_3O_8. The writer has recently commented at length upon the limitations of this method,[2] and has nothing further to add at present.

The most striking feature in the extraction process described by Mr. d'Aguiar is the use of hydrochloric acid to dissolve the soluble material in the ore, followed immediately, without filtration, by the use of sulphuric acid to precipitate radium and barium as sulphates. From the standpoint of economy this procedure could be justified only if it can be demonstrated that sulphuric acid alone will not give equally good extraction. By the addition of sulphuric acid without previous filtration the radium and barium are thrown out of solution with the tailing and must be recovered by a sliming process, which entails the difficulties of carbonation and the recovery of the radium from the slimes. When hydrochloric acid is used as extractant, it is usually with the purpose of separating the solution from the tailings immediately by filtration and obtaining in a single step a high-grade radium-barium sulphate by precipitation. If this procedure is to be sacrificed (and in some cases it is not applicable), one would naturally expect to use the cheaper acid, sulphuric, for the whole digestion of the core, unless it can be conclusively demonstrated that hydrochloric followed by sulphuric gives a better result.

Mr. d'Aguiar's statement that no radium is found in carbonate liquors can scarcely be entirely correct. Barium carbonate must be present up to its solubility in the liquor in question and radium would be contained corresponding to the radium-barium ratio prevailing. For all practical purposes, however, the amount of radium is too low to represent any material loss. Mr. d'Aguiar does not state at what point of the process, nor how, the lead was removed.

The practice of holding radium tubes, even with forceps, while tubing the salt must be regarded as a very hazardous one. In the work of the Bureau of Mines a very simple arrangement was devised which proved entirely satisfactory. A one-hole rubber stopper was forced into a heavy glass inkwell with a flat base, which prevents the possibility of tipping over. The bottom of the tube to be filled is then inserted for a short distance into the hole in the stopper, which holds it firmly in a vertical position, and at the same time permits all the necessary play for tapping during the tubing operation.

The practice of discarding uranium is very regrettable, but, as Mr. d'Aguiar states, the market conditions have not justified its recovery. Some companies have run the byproduct into sumps from which it could be recovered if a demand ever arises. It is not at all improbable that a use will some time be discovered for this rare metal which will make it extremely valuable.

Regarding the practice described for the measurement by radium of the emanation method, a chamber of 10 liters capacity seems unnecessarily large. Physicists in the past have complained that chemical methods are crude in being able to deal quantitatively with matter only in relatively large quantities. This criticism would appear just if we admit that it is necessary to employ a capacity of 10 liters in measuring a volume of emanation which itself is of the order 5×10^{-3} cu.mm.

The use of such a large volume entails certain disadvantages. The volume of air to be dried is so great that one cannot use conveniently a small system containing concentrated sulphuric acid, but is forced to

*Published with the permission of the Director of the Bureau of Mines.

resort to the use of solid calcium chloride. On account of the danger of adsorbing radium emanation, it has not been regarded as good practice to pass it over porous solids. The only reason which requires the use of such large volumes is in itself not sound in principle, since the emanation to be measured is removed from the solution by aspiration at ordinary temperature instead of by boiling. It has long been realized that the complete aspiration of radium emanation from water at ordinary temperature is a slow and uncertain process. This point has recently been reiterated by M. Walter Mund[3] in another connection. By far the superior practice consists in boiling the solution; the volume of steam produced sweeps it out completely in a short time and is again condensed so that the volume of air actually introduced is much smaller and an electroscope of ½ liter capacity is sufficient for all purposes.

In connection with the standardization of emanation chambers, the preparation of a standard solution from 1 mg. of radium measured by the gamma ray method would scarcely afford the desired degree of accuracy. It is much better to make up a solution employing a large quantity of salt, which can be more accurately measured, dilute this solution to the desired standard and return the remainder immediately into the form of salt. It is also to be borne in mind that fluctuations in temperature or pressure will produce corresponding errors in the result obtained with a calibrated chamber, unless correction is made. When both of these errors happen to be in the same direction, they can easily amount to 2 or 3 per cent. The ideal system is to have an air bath which can be regulated to correspond to the prevailing barometric pressure on each day so that all emanation chambers can be filled with an air concentration corresponding to that at which they were standardized.

Mr. d'Aguiar's method described for the treatment of sulphates in order to bring the radium into solution for measurement involves a rather difficult operation in duplicate. If the silica content of the sulphates is too high to render the sodium carbonate fusion method applicable,[4] then the bisulphate fusion method of Barker[5] may be used conveniently, or the SiO_2 may be removed by HF before the carbonate fusion.

It is not clear whether Mr. d'Aguiar's statement in a footnote, to the effect that the nitric acid extraction method is needlessly expensive and that only 1 g. of radium has been produced by it, is general, or whether it refers only to the experience of his own company. If he means it as a general statement, it may be of interest to recall that the Bureau of Mines produced between 8½ and 9 g. of radium element by the nitric acid method, which was not only found to be entirely satisfactory but which was above criticism from the cost standpoint, as the following statements will show: The costs published in Bulletin 104 by the Bureau of Mines were $37,500 per gram of radium. These costs were estimated from the production of 1 g. during the course of operation. It has been supposed by some radium producers that the estimate was too low, but, as a matter of fact, it has proved to have been fairly close. When the entire operations of the National Radium Institute were brought to a close, it was found that the net expenditures of the corporation, after deducting for the sale of the plant, byproducts, etc., was a little over $300,000. (No allowance has been made for 30 tons of high-grade black oxide of uranium produced as a byproduct, which has not yet found a market.) Add to this an overhead of $50,000 on the part of the Bureau of Mines, which is a very liberal estimate, divide by 8.9 g., the amount produced, and a cost is shown of $39,325 per gram. It is not meant to imply that this would be a fair figure today under the present cost of chemicals, labor, etc., but it is meant to state that for such ores as are amenable to nitric acid extraction it can compete in cost, when the nitrates are recovered from the tail liquor and the nitric acid is regenerated, with any other method hitherto proposed. In addition it possesses the distinct advantage of furnishing in a single step a high-grade radium-barium sulphate which can be directly converted into soluble form and introduced into the crystallizing system, without the troublesome steps necessary when a less pure sulphate is produced by a sliming method. In the writer's opinion, radium producers who have carnotite ore reasonably free from sulphate, which is, therefore, amenable to nitric acid extraction, make a mistake in overlooking the possibilities of the nitric acid method.

In closing, the writer would like to say that the radium industry is much indebted to Mr. d'Aguiar for the interesting information contained in his two papers and that it is only to be hoped that he will supplement it with statements regarding the relative amounts of radium passing through the different stages of the process described, and give other details and data which would be of the greatest value to those engaged in the radium industry.

Explosion Hazard in the Darling Process of Electrolyzing Sodium Nitrate

To the Editor of Chemical & Metallurgical Engineering

Sir—In reading the first installment of Mr. Batsford's valuable article on "Metallic Sodium," which appeared in your journal for May 10, I find that, on page 891, following his description of the "Darling Process Using Sodium Nitrate," he says: "Unfortunately the explosion hazard was too great a drawback, and the process was abandoned about the year 1905." As expert special agent in charge of the chemical industries at the census of 1900 I investigated the Darling process, then being operated at the works of Harrison Bros. & Co., Philadelphia, and on pages 50-51 of Bulletin 210 of the Twelfth Census of the United States I have given a description of the process. During my investigation I learned that the quantity of metallic sodium accumulated in storage at the works had become so great the city authorities, fearing accidents, compelled the cessation of operations. It was my understanding that the menace was in the product and not in the process and that this menace will hold for any and all processes for the isolation of sodium. This is a factor of great weight in determining the location of a plant for this industry and in designing the methods for collecting, handling and storing the sodium.

American Iron and Steel Institute

Twenty-first General Meeting at Hotel Commodore, New York City—Judge Gary's Opening Address—Technical Program With Papers on Australian Iron and Steel Industry, Electrification of Steel Mills, Adirondack Iron Ores, Fuel in Open-Hearth Practice, and Gas and Air Valves for Open-Hearth Furnaces

THE twenty-first general meeting and annual spring session of the American Iron and Steel Institute was held on Friday, May 26, 1922, at the Hotel Commodore, New York City. The program consisted of a morning session with an address by President Elbert H. Gary and technical papers, luncheon, an afternoon session of technical papers and discussion, and a banquet in the evening, followed by impromptu speaking in response to the call of President Gary.

There was a large attendance of the members and their guests at both the morning and afternoon sessions and at the banquet. A general tone of good-spirits and optimism was evident and confidence in the return of good conditions to the industry was evidenced on all sides. Field Marshal the Right Honorable Earl French of Ypres was the guest of honor at the banquet and spoke briefly in appreciation of the American iron and steel industry.

Morning Session

The morning session was opened with the customary address by the president of the Institute. Judge Gary opened his remarks with an appreciation of the services to humanity in general and the iron and steel industry in particular rendered by the late Dr. Henry M. Howe, whose memory was honored by a silent standing tribute on the part of the whole assemblage.

President Gary then spoke of the dinner given on May 18 by President Harding, who at that time had forty members of the A.I.S.I. as his guests at the White House. The newspapers were in the main correct in their reports of this meeting, at which President Harding came out frankly and asked the iron and steel industry to do all in its power toward adopting a uniform eight-hour day. The matter was discussed fully among those present and a motion was passed that Judge Gary appoint from the A.I.S.I. a committee whose duty it should be to make a thorough and unbiased investigation as a basis for a report and recommendations upon which the A.I.S.I. might take such action as then seemed appropriate. It was urged on all present that they extend their prompt co-operation to this committee, furnishing all the data pro and con which their industrial connections made available, and always keeping in mind that President Harding's wishes should be fulfilled if such proved to be at all possible.

Judge Gary's Address

President Gary then delivered his address, the subject of which was "Current Legislation." After pointing out the necessity for full and impartial administration of all the laws on the statute books and urging the patriotic duty of all iron and steel men to see that this course was followed, he touched on the legislation now before Congress on the tariff, government regulation and soldiers' bonus, giving his opinion of the course that should be followed that all in the country might derive the most benefit. The sales tax was advocated, whether the bonus legislation passed or not, as being fairer to all concerned and better for the business life of the country than the methods of revenue raising now in vogue. The address closed with a word of optimism and encouragement as to the present and future of the iron and steel industry.

Address by Sir William B. Peat

Following Judge Gary's address, Sir William B. Peat was introduced to the meeting. Sir William has long been influential in iron and steel circles and, an early member of the Iron and Steel Institute of London, was instrumental in the founding of the A.I.S.I. He spoke briefly on the position of the iron and steel industry of the United States in world trade and expressed the opinion that the United States should seek the financing and control of the industries of other countries as England had done a hundred years ago, stating that only in this way could world trade and industry quickly regain their former level.

Iron and Steel in Australia

A paper on "The Development of the Iron and Steel Industry in Australia" was read by David Baker, general manager of the Broken Hill Proprietary Co., Newcastle, New South Wales. The important iron ore resources of Australia are stated to be as follows: Western Australia, 97,500,000 tons; South Australia, 130,000,000 tons; Victoria, 750,000 tons; Tasmania, 41,900,000 tons; Queensland, 500,000 tons, and New South Wales, 53,017,000 tons. There are numerous other rich deposits; but due to their present inaccessibility they were not listed.

The manufacture of iron and steel has made various sporadic starts in the different Australian states; but only in New South Wales, where the industry was commenced in 1852 at the Fitzroy Iron Works, has the development been steady. Following the formation of this company, the Lithgow Iron Works was founded in 1874, becoming the present Hoskins Iron & Steel Co., Ltd., in 1908. The Broken Hill Proprietary Co., founded in the early days of Australian gold mining for the production of gold, silver and lead, originally purchased the iron mines at Iron Monarch and Iron Knob for use in supplying flux for its lead smelters at the Port Pirie Works. In 1911 this company made an investigation of the possibilities of steel manufacture and then commenced this manufacture at Newcastle in 1915. The production of these two last companies is as follows: Hoskins Iron & Steel Co., Ltd., 150,000 tons of pig per annum; Broken Hill Proprietary Co., 600,000 tons of steel per year. There are numerous other companies of less importance for the production of pipe, wire, black and galvanized sheets and other materials.

Afternoon Session

Relation of the Doctor to the Steel Plant

The first paper of the afternoon session was an interesting exposition of the "Relation of the Doctor to the Steel Plant," by Dr. L. A. Shoudy, chief surgeon of the Bethlehem Steel Corporation. Dr. Shoudy pointed out the importance of employing only the highest class of physicians and installing the best of hospital and medical equipment. The important function of the doctor is, by anticipating and removing the causes of ill health in environment and in the human machine, to keep production and efficiency at a high level. In conclusion, he stated that in times of trouble the worker looks on the doctor as a friend who understands and hence the right type of doctor can form a valuable contact between the steel company and the workers.

Electrification of Steel Plants

Wilfred Sykes, of the Steel & Tube Co. of America, read a paper on "The General Effect of Electrification on the Operation of Steel Mills," which stated that it is important that those concerned in steel mill operation should understand the essentials of electrification, as the extension of the steel industry in the future will consist as much of modernization of the old mills as of building new mills, and in this case the main drives will all become electric, as the auxiliary drives now are. The paper then proceeds to give numerous and illuminating examples of operation of electric drives for main rolls and auxiliary mills. An interesting chart shows the progress in use of electric drives on main rolls from 1906 to 1921, the total horsepower in use having increased in that time from about 50,000 hp. to approximately 925,000 hp.

Mr. Sykes gives some interesting figures on the delays resulting from the electrical driving of the reversing drive of a 30-in. universal plate mill at the South Chicago works of the Illinois Steel Co., which was installed in 1907 and was the first to operate. During a total working time of 100,000 hours since that time the mill has had a total delay of 525 hours due to electrical troubles. In 1920, after 13 years' operation, there were no delays, although this mill rolled in this year 20 per cent more than in any of the first 10 years of its life.

Use of Fuel in Open-Hearth Furnaces

Herbert F. Miller, Jr., assistant superintendent of the Lackawanna Steel Co., in a paper on "Methods of Using Fuels in Open-Hearth Furnaces," stated that the field in which ideas for developing power of open-hearth fuels are hidden has barely been scratched. From experiments covering the past ten years on the use of various fuels in open-hearth furnaces he found methods of producing much better flames than are in general use in open-hearth practice. In a producer gas type furnace with a single brick gas port, oil was used for fuel and was introduced through a water-cooled tuyere which projected across the uptake and terminated just short of the nose of the port. This tuyere was pulled back until it terminated over the uptake. The result was such an intensely hot flame that the arch of the port melted and the roof of the furnace burned. However, this flame was used a sufficient time to show that the time of the heats could be reduced from 6½ hours to 4 hours. The reason of the high heat was that the great speed of the oil fuel across the uptake and through the gas port caused it to act as an aspirator for the preheated air in the uptake. Hence the vaporized oil and the air united under pressure and at great speed in a mixing chamber of small cross-section and the condition approached the ideal for perfect combustion. Similar experiments on other fuels and in specially built ports proved that these effects could always be reached. The trouble is that the furnaces now in use cannot stand the heats obtained in this manner. Mr. Miller suggested the construction of open-hearth furnaces along the lines followed to produce the modern high powered blast furnace and that eventually it will be possible to tap heats charged with scrap and cold pig iron in three to four hours after starting to charge, when conditions of high pressure air and gas are developed.

Iron Ores of the Adirondacks

In 1916 F. S. Witherbee, of Witherbee, Sherman & Co., read a paper on this subject. F. L. Nason, the geologist of this company, now presents a paper which supplements and gives further details on this subject and is entitled "The Importance of the Iron Ores of the Adirondack Region." The paper states that there are about 250,000,000 tons of titaniferous ores, and that the total tonnage of both titaniferous and magnetite ores, known and prospective, is 1,736,000,000 tons. Of this amount there is 186,000,000 tons of ore assured. At the present rate of production, about 1,500,000 yearly, the yield to be expected from the rest of the field will be known long before this amount is exhausted.

The paper states also that this region is capable of producing not less than 600,000,000 tons of 61 to 65 per cent concentrates of bessemer grade in phosphorus, of which probably one-half would be "special low phosphorus." Unit for unit, these concentrates can be marketed on even terms, at some point not far east of Buffalo, with the best of the Lake ores.

Gas and Air Valves for Open-Hearth Furnaces

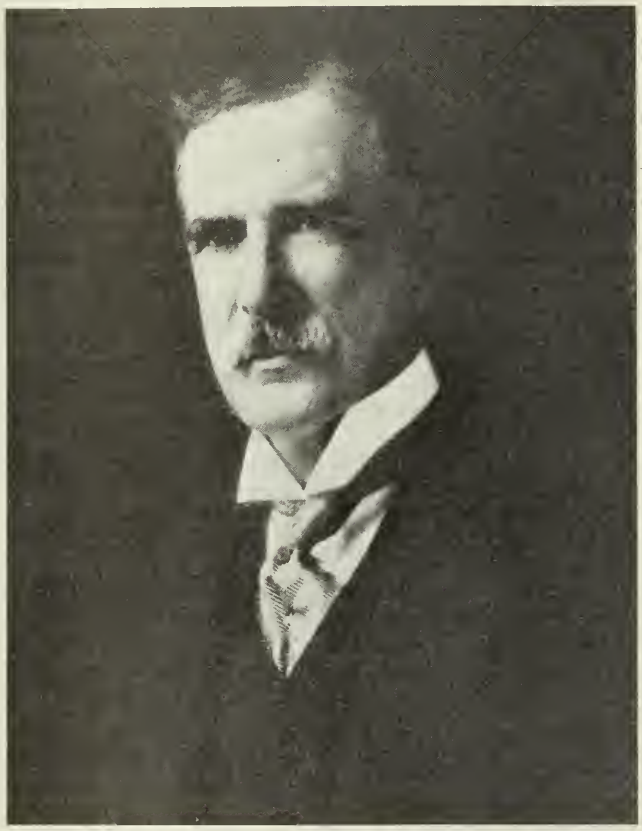
William C. Bulmer, of the Carnegie Steel Co., in a paper on "Gas and Air Valves for Open-Hearth Furnaces," traced the development of these valves from the earliest Siemens furnace down to the types in use today. He stated that the chief requisites of a proper valve are an effective seal and an unrestricted passage. The paper divides valves into three groups—namely, one-way, two-way and four-way, depending upon the number of directions of gas or air passage through them. The one-way group alone offers means of regulating the flow to and from each checker chamber without additional equipment. This valve also permits any desired proportion of the waste gases to be put through either chamber. By regulation of the incoming gases also during periods of shutdown, such as Sundays, a much better temperature can be maintained.

Valve types are classified in this paper as slide, butterfly, mushroom and movable hood—also as dry, refractory-lined, water-cooled and water-sealed. The various advantages and disadvantages of these different qualities are given. From these data the paper concludes that the one-way, water-cooled slide valve with inclined seat comes nearest to perfection in so far as the requisites of effective seal and unrestricted passage can be obtained with good mechanical construction, accessibility for repair, low maintenance cost and various other factors.

Henry Marion Howe

HENRY MARION HOWE died at his home at Bedford Hills, N. Y., on Sunday, May 14, 1922, from a malady which had confined him to his house for more than a year. Living to the ripe age of 74 years, his achievements may be fittingly expressed in the words with which Albert Sauveur conferred the John Fritz Medal:

"Lover of justice and humanity,
"Public servant and public benefactor,
"Master of the English language,
"Loyal and devoted friend,
"Untiring and unselfish worker in an important field of science,
"Stimulating teacher, inspiring investigator and generous collaborator,
"Voyager in realms but dimly perceived by fellow-workers,
"Lone explorer of fields destined to yield rich harvests to future generations,
"Man of genius, honored and loved the world over."



HENRY MARION HOWE

Henry Marion Howe was born March 2, 1848, at Boston, Mass. His father was Dr. Samuel G. Howe, famous for his service to Greece in her war for independence (from 1824 to 1830) and later for his labors in the instruction of the blind. His mother was Julia Ward Howe, author of The Battle Hymn of the Republic," and leader in many reforms.

He was graduated in 1865 from the famous Boston Latin School, and four years later received his degree as Bachelor of Arts from Harvard College. Thus equipped, he entered the Massachusetts Institute of Technology, which gave him in 1871 the degree of "Graduate in the Department of Geology and Mining Engineering"—a cumbrous title for which the institution substituted, a few years later, that of "Bachelor of Science." And Harvard made him Master of Arts in 1872, and Doctor of Laws in 1905.

With the exception of approximately five years devoted to the metallurgy of copper, during which he inaugurated copper smelting in Chile, designed and built the works of the Orford Nickel & Copper Co. at Capelton and Eustis, in the Province of Quebec, Canada, and at Bergen Point, N. J., and managed the Pima Copper Mining & Smelting Co. in Arizona, Dr. Howe's whole professional life had been devoted chiefly to the development of the iron and steel industry, as superintendent of steel works (Joliet, 1872, and Pittsburgh, 1873-4), consulting metallurgist, teacher of metallurgy, investigator, interpreter, writer and presiding officer. While acting as consulting metallurgist he was lecturer on metallurgy at the Massachusetts Institute of Technology from 1883-1897, professor of metallurgy at Columbia University, 1897-1913, and professor emeritus, 1913-1922.

For the last fifteen years he declined as far as practicable all professional business in order to devote himself exclusively to what had clearly become the great scientific mission of his life, a task unfortunately not completed. Dr. Rossiter W. Raymond, in an address in 1917, thus describes it:

"It gives me pleasure to fancy, whether or not the fancy be also fact, that I remember the beginning of that mission, forty-odd years ago. In 1871, the first year of the existence of the American Institute of Mining Engineers, Mr. Howe, then just graduated from the Massachusetts Institute of Technology, became a member of the new organization. His two earliest contributions to its *Transactions*, 'Blast-Furnace Economy,' in volume 3, and 'Thoughts on the Thermic Curves of Blast Furnaces,' in volume 5, indicated already that he was making a scientific study of practice. But between the dates of these papers a famous controversy was inaugurated in the forum of the Institute by the brilliant paper of Alexander L. Holley, *primus inter pares*, entitled 'What Is Steel?' In his controversy eminent metallurgists like Wedding, chemists like Prime, and expert captains of industry like Metcalf vigorously took part; but of all the knights of the tourney, none rode a straighter course or laid in rest a sharper lance than Howe, whose paper on 'The Nomenclature of Iron' ardently advocated a scientific as distinguished from a commercial nomenclature. To tell the truth, the battle had a commercial origin. The real question at issue was not, What is steel? but, What may fairly be called steel at the custom house?

"Well, there was even an international committee on the subject, and the committee made a report. The tariff difficulty was adjusted somehow; the antagonists shook hands; the thunder of the captains of industry and the shoutings died away. But one man continued the inquiry fiercely in his own soul. Henry Marion Howe, before whom the dust of the controversy loomed like a giant Afrite still defying attack, devoted his life thenceforth to the mighty conundrum, What is steel?"

In 1889 appeared in book form his "Metallurgy of Steel" after running serially in *Engineering and Mining Journal*. Let Dr. Howe's associate, Bradley Stoughton, tell of its influence:

"Before Howe wrote his great book, 'The Metallurgy of Steel,' steel making was a practice rather than a science, a series of operations producing material whose quality was sometimes uncertain and whose defects were not understood or explainable. The science of metallography was in its infancy; the use of the microscope in steel laboratories was scarcely heard of. This monumental book, in more ways than one marks an epoch in the history of steel metallurgy; it collected and collated all the valuable information in English, French and German. So thoroughly and so comprehensively had Howe performed the task that the previous literature of steel became of secondary importance, scarcely necessary for reference, because its most important data were included in this one concise volume.

Howe's Leadership Recognized Internationally

"From that time the leadership of Howe in the scientific and literary development of the metallurgy, metallography, heat-treatment and physical properties of iron and steel was recognized internationally. He was possessed of the qualities which eminently fitted him for this leadership. Gifted with a tact, a charm of personality as a presiding officer, an excellent speaking knowledge of French and German, he stimulated his audiences and brought out an active debate in a convention in any language; no one in this field had a command of the English language comparable with his; he developed clarity of expression which enabled him to clothe his thoughts in language that could be readily understood; his devotion to the truth was single minded and predominant; he was not only an able investigator and interpreter but he was an organizer of research to produce the most effective results from the experiments of himself and those working under or with him. He did not waste time with experiments, because he had students available to do the manual work; he did not duplicate work which had already been done, but he preceded each research with careful study of the information already available; he sought to investigate first those problems which stood in the way of progress, which were needed to fill in the gaps of knowledge, or whose solution would most enlarge our field of vision; he planned the work in advance; he did not tolerate a haphazard experimentation; he worked with a desire to reach a definite goal by the shortest possible method; he did not build his bridge without designs and calculations, but rather he prepared in advance in order that each step might count."

His Masterly Work on the Metallography of Steel and Cast Iron

All these labors were to be collected and interpreted in a series of monographs. Only one of them has been completed, "The Metallography of Steel and Cast Iron," appearing in 1916. This book is not a text-book, repeating what is generally accepted already. Covering the field in which others have meritoriously labored, it propounds, suggests and prophesies new truth and new views of truth. It is a product of the two kinds of genius, the genius which consists in an infinite capacity for taking pains, and the genius which with happy intuition surveys, divines, co-ordinates and interprets the cosmos in the chaos. It was hailed by scientists everywhere. Thus Sauveur:

"Prof. Howe, in his masterly book, "The Metallography of Steel and Cast Iron," reviews exhaustively and examines critically, as he alone can do, every view at all worthy of recognition, dealing with the subject he covers. I believe that any responsible author who has ever expressed a reasonable opinion on any subject dealing with the metallography of iron and steel will find his views recorded and discussed in this book. Prof. Howe then proceeds to weigh with great fairness and extraordinary intelligence and lucidity the arguments or evidence supporting the different views, and draws his conclusions accordingly. His method is that of a mathematician solving a problem in which each factor is given its proper value. In this way Howe has rendered to metallurgists an inestimable service; and he alone could render it. Where most of us could see only chaos and obscurity, he is able to bring order, and to discover the light that, under his skillful manipulation, soon illuminates the darkest corners. . . .

"This, I think, is his greatest achievement—the marvelous co-ordination which he has brought into the science of metallography through his genius and his labor, tremendous in quantity, marvelous in lucidity. To him more than to any one else we owe the quick rejection of weak or ill-supported theories, in favor of the survival of the fittest—a process so necessary to the advance of any branch of human knowledge."

Completion of a series of such great works was undoubtedly prevented by the fact that during the Great War Dr. Howe acted as chairman of the Engineering Division of the National Research Council, giving his entire time and energy to the many problems in its charge. One of the many problems successfully solved was curing "haircracks" in airplane engine crankshafts. In this instance Dr. Howe applied the results of a study made by the Army and Navy Ordnance Departments on wastage in the manufacture of nickel steels of high transverse strength.

His Service as President A.S.T.M.

Dr. George K. Burgess also dwells upon the services rendered by Dr. Howe, during the four terms he acted as president of the American Society for Testing Materials:

"Dr. Howe always illuminated any subject which he considered and also took very active part in the discussion of any subject of interest to him and had a wonderful ability of expressing vividly and tritely the major facts as well as the details of any metallurgical problem, however recondite. His very logical mind and comprehensive grasp of the theoretical as well as the practical sides of questions relating to properties and testing of materials made him an exceedingly valuable leader in A.S.T.M. activities. He was always most frank and fearless, at the same time courteous and considerate, in expressing and maintaining his ideas in verbal discussion and in writings. I am certain that his balance, foresight and ability must have had a predominating and far-reaching influence in framing not only questions of Society policy but also in the development of technical and scientific problems. He with Professors Lanza and Merriman held each in his own field of engineering a unique place of dominance for many years in the A.S.T.M. councils. All three were professors, and each of them put the imprint of his personality into the formulation of its ideals. As far as metallurgy is concerned, the late Dr. Dudley and Professor Howe, one representing the practical use of specifications and the other more interested in development of correct concepts and securing progress by research, were easily the leading minds in the early days of the A.S.T.M."

Prof. William Campbell of Columbia University, who

was associated with Dr. Howe for many years, pays his tribute:

"In the death of Professor Howe this country has lost one of the great teachers. In other places various accounts of his distinguished services in his chosen profession have been given and also lists of his publications and of his well-earned honors, but here perhaps a word or two of appreciation of the man himself may not be out of place.

"Those of us who had the privilege of attending his courses or working with him in his laboratory or even only hearing him deliver one of his numerous contributions to science have been struck with his remarkable clearness of thought and of expression as well as his keen penetration and masterly interpretation of results. Yet with all his brillance of mind he was sympathetic and patient with those of his associates less happily endowed. And his patience was that of Job.

"In the lecture room his modesty seemed to increase as his reputation became greater. He seldom, if ever, referred to his own contributions, but always gave credit to others, even where he himself had done all the planning. His method of presentation was so simple and so logical and his illustrations so homely that the dullest of us could not help but understand him, with the result that his courses seemed to be the easiest in the school.

"In the laboratory his kindly personality and fatherly interest in us all made him beloved by everyone. He spared no pains in training his men to do research in the scientific, orderly manner, for he had no respect for the old cookbook methods.

"Particularly were his characteristics noticeable in guiding us in our research. An indefatigable worker himself and of great painstaking in systematizing and planning work, yet he was never intolerant or sharply critical when things did not turn out satisfactorily because his advice had not always been followed. 'Try again' was his motto and when the work was done his praise and appreciation well repaid for all.

Aided Impecunious Students Delicately

"Another side of his character known to but few was his sympathy for the student who had to work his way. He constantly made opportunities for such a man to make a little extra money and he was always on the alert to see that such opportunities came his way. On more than one occasion where the offer of actual money would have hurt a sensitive person, Professor Howe thought up some research that needed doing and which at some future time might have some technical value and therefore ought to be paid for, and it was paid for generously.

"In spite of his busy life, for he worked himself to the limit, he found time to have his students home to lunch and dinner and then talking shop was barred. And yet we all came away feeling we had had a very pleasant time and rather proud of ourselves that we had been able to discourse so fluently and so brilliantly on all kinds of subjects—a thing which had never happened to us before."

W. P. Barba, a friend of Dr. Howe for many years and who collaborated with him in the preparation of the recently published article on "Acid Open-Hearth Practice in the Making of Fine Steels," writes:

"The passing of Dr. Henry Marion Howe creates an irreparable loss to the philosophic and practical consideration of the making of the utmost progress in the production of quality products in the iron and steel industry. Dr. Howe's rare insight into, first, the practice, and then the philosophy surrounding the practice of this manufacture was so deep and wide that the writer can think of no one at present prepared to step into the place vacated by Dr. Howe.

"His many publications, accurately collecting and compiling practical data, deducing therefrom the correct theories so often developed, first, through practice and then disseminating so freely and fully the correct reasoning from this observed practice, furnished to the world of iron and steel a medium of full and correct thought which has so far been unmatched by the work of any other observer.

"Dr. Howe's unfailing courtesy, unflagging energy and immense industry were directed, for more than one generation, to the end that the practice of America first and of the world in general should be correctly guided, so that the practical results, coming through the many establishments engaged in the manufacture of these products, should be of maximum benefit.

"Dr. Howe will be missed by his many friends, by his thousands of admirers and disciples, and the writer hopes that the followers of Dr. Howe will pattern after his most meritorious example."

Corrosion Tests of Chromium Steels

It appears from the series of tests which the U. S. Bureau of Standards has carried out upon the corrosion of chromium steel that the behavior of the material when subjected to the acid test is not a sure criterion of its resistance to atmospheric corrosion. Of all the alloys examined, a high nickel-chromium steel, invar, pure iron and medium carbon steel (very slowly cooled from a high temperature) were the most resistant to hydrochloric acid as measured by the loss of weight per unit area per day. High-chromium steels, for example, containing 13.7 per cent Cr and 0.29 per cent C, were found to be attacked by acid very much more readily. However, when the same specimens were subjected to a weathering test, consisting of a partial immersion in water and exposure to the air, the order of resistance was almost completely reversed. The high-chromium steels were the ones to withstand the treatment best, the low-chromium ones and the pure iron showing rust spots early in the test. The combination of both nickel and chromium appears to make the steel resistant to both acid and weather attack. In general, the steels which were quenched were found to resist corrosion better than the same material in the annealed state, but the differences found were much less than the differences resulting from composition changes, thus indicating that composition rather than treatment should receive primary consideration. Additional results will not be ready for some time.

Spectroscopic Analysis of Bronzes

The Bureau of Standards, Washington, D. C., has completed the examination of five bronzes for impurities with the purpose of establishing the spectrographic method for quantitative estimation of small amounts of aluminum and silicon which are detrimental in bronze or brass castings. The method is simple, successful and sufficiently accurate. A report on this practical application of spectrum analysis was presented at the Non-Ferrous Metals Committee meeting on April 24, and a paper entitled "Spectrum Analysis in an Industrial Laboratory" was read before the Institute of Metals Division, February, 1922, by Messrs. Bassett and Davis, of the American Brass Co.

Effect of Sulphur on Rivet Steel

Maximum Sulphur Now Allowed (0.045 Per Cent) Is at Least 0.01 Per Cent Below the Quantity Where Sulphur Will Damage the Strength of Well-Made Rivet Steel, as Far as Its Performance Can Be Predicted by Standard Tests

By ERNEST E. THUM

A "PRELIMINARY REPORT of the Joint Committee on Investigation of Phosphorus and Sulphur in Steel" has just been issued as a preprint of a paper to be presented before the American Society for Testing Materials, Atlantic City, June 28. The text merely recounts the number and kinds of tests, and presents thirty-three diagrams summarizing the results. Complete publication will ultimately be made as a Bureau of Standards technologic paper and presumably will contain all information available on the method of steel making and rolling, numerical results of tests, photographs of fractures and microscopic studies of structure. "While the Joint Committee has received all the test data in this investigation, it prefers to defer any extended discussion of the results and the drawing and publishing of formal conclusions therefrom." This attitude of the committee is unfortunate, for there is a vast amount of data contained in the pamphlet (over 5,000 physical tests and 1,000 chemical analyses were made) and few metallurgists will have the time necessary to analyze it and seek out its meaning. It must therefore be understood that only the diagrams presented herewith are vouched for by the committee—the tables (except Table I), the discussion and the conclusions have been deduced by the present writer.

Steels Used

Thirteen 75-ton heats of basic open-hearth steel varying in sulphur from 0.03 to 0.08 per cent, and one with 0.18 per cent sulphur, were made and rolled into 1-in. bars by the Carnegie Steel Co. This sulphur is "residual"—i.e., due to sulphur in the charge and fuel and not to additions of sulphides after melting. Physical and chemical tests on the material were made at Watertown Arsenal and at the U. S. Naval Engineering Experiment Station, Annapolis. Twelve complete analyses were made on each heat, giving the very uniform results shown in Table I. No nickel or chromium was found. Heat F is high in both manganese and carbon; this composition is unmistakably reflected in the physical tests, and in view of its very low sulphur contents, it would have been proper to omit this steel from the series. This done, the composition of the various materials may be regarded as: Carbon, 0.11 per cent; manganese, 0.43 per cent; phosphorus, 0.01 per cent.

TABLE I—AVERAGE CHEMICAL COMPOSITIONS, WITH MEAN DIVERGENCES

Each value is the average of separate analyses on 14 samples from each heat. The heats are arranged in the order of increasing sulphur contents.

Heat Letter	Ingot Hot or Cold	Sulphur, Per Cent	Carbon, Per Cent	Manganese, Per Cent	Phosphorus, Per Cent
A...	Cold	.0282 ± .0015	.136 ± .0037	.426 ± .021	.0062 ± .0005

K...	Hot	.0580 ± .0030	.115 ± .0050	.411 ± .0087	.0105 ± .0025
E...	Cold	.0606 ± .0033	.104 ± .0037	.457 ± .006	.0105 ± .0010
D...	Cold	.0608 ± .0012	.094 ± .0040	.385 ± .015	.0127 ± .0020
P....	Hot	.0633 ± .0018	.116 ± .0037	.432 ± .005	.0240 ± .0030
S....	Hot	.0695 ± .0028	.104 ± .0043	.420 ± .020	.0117 ± .0003
R...	Hot	.0834 ± .0033	.106 ± .0037	.472 ± .0025	.0112 ± .0030
M...	Hot	.1793 ± .0027	.106 ± .0037	.512 ± .0075	.0060 ± .0030

Even after eliminating heat F, manganese, unfortunately, varies from 0.35 to 0.51, and tends to go up with the sulphur. Therefore some of the effects of sulphur may be masked by this other element, and in the discussion which follows it should always be remembered that % S + 0.40 = % Mn.

Tests on Rivets

Two hundred rivets were made of each steel and tested in various ways. Twenty rivets from each test were upset two-thirds their length, ten hot and ten cold, with no failures. Ten hot rivets of each heat had their heads flattened to 2½ times the shank diameter, and six more from each heat had their shanks flattened hot to $\frac{3}{32}$ in. at the edges without failures. Eight cold rivets from each heat were bent flat upon themselves in the condition as received, without failures. Eight rivets from each heat were bent flat upon themselves after quenching from 940 deg. C. (1,725 deg. F.); the only failures recorded were in the 0.18 S steel.

The conclusion is that sulphur up to 0.10 per cent in well-made rivet steel does not affect the hot or cold shortness. All the ingots and billets rolled satisfactorily, with exception of heat P, which cracked slightly in blooming.

Interpretation of Curves

To aid in fixing the indication of the test results, smooth curves (in most cases straight lines) were penciled which approximated the general trend of the somewhat jagged lines given in the report and reproduced here. Values for 0.03, 0.06 and 0.10 per cent sulphur were then scaled from this tentative median.

It may as well be recognized immediately that such a plan would involve a large personal factor, and if some of the readers of the report will take the trouble to do it for themselves, perhaps their results would vary several per cent from those given in the table. However, in this particular attempt, sample F was disregarded altogether, and samples A and G somewhat minimized on account of their high carbon. Sample P has (comparatively speaking) very high phosphorus. E and D, being identical in sulphur, were given special weight. A sincere effort to avoid undue influence of the single point out at 0.18 per cent sulphur was also made.

Tension Test

Inspection of Fig. 1 from the report and Table II by the present writer indicates that in this series of rivet bars sulphur up to 0.10 certainly (and perhaps up to 0.18) has practically no effect on the tensile properties. The curves are nearly horizontal. Results as determined are quite uniform; variations from a straight line at samples F, G and P may be ascribed to irregularities in chemical composition (high manganese, carbon and phosphorus respectively). These facts may be summarized in the statement that:

A basic open-hearth rivet steel with composition: C 0.11, Mn 0.43, P 0.01 and S 0.03 has the following tensile properties when tested in 1-in. bars, as received from the mill: Tensile strength, 49,500 lb. per sq.in.; yield point, 36,000 lb. per sq.in.; reduction in area, 72 per cent; elongation in 2 in., 44 per cent. Each addi-

tional 0.01 per cent S up to 0.10 decreases the tensile strength 200 lb. per sq.in. and increases the yield point 100 lb. per sq.in.

One-inch bars tested transversely, in the condition as received (Fig. 4), have yield point and reduction in area much lowered, a symptom of transverse weakness independent of the sulphur content. Reduction in area is further affected markedly as the sulphur goes up, although all the tensile properties seem to show a slight downward trend with increasing sulphur.

After annealing for 30 minutes at 925 to 950 deg. C. and furnace cooling, the greatest change in tensile properties from those given in the 1-in. rivet bars as received is a pronounced drop in the yield point. Fig. 2 shows that the properties plot against sulphur content in what is nearly a horizontal straight line except that the yield point seems to increase slightly with increasing sulphur. The evidence seems to be that:

Annealing these bars for 30 minutes at 925 to 950 deg. C. and furnace cooling lowers the tensile strength 4,000 lb. per sq.in., the yield point 8,000 lb. per sq.in., but does not affect the reduction in area or elongation.

Transverse properties are substantially unaffected by annealing.

Quenching Accentuates Effect of Sulphur

Quenching in water after 30 minutes or 1 hour at 925 to 950 deg. C. increases the tensile strength and yield point of 1-in. rivet bars and 1-in. slabs (transversely) very materially, as can be seen from an inspection of Table II and Figs. 3 and 6. Elongation is

TABLE II—TENSILE TESTS

Elongation	32	35	37	32	33	31

reduced correspondingly. The curves for reduction in area of quenched transverse specimens (Fig. 6) drops with high sulphurs to a much more pronounced extent than any of the previous ones.

It may now be desirable to review the data on tensile properties of rivet steel containing sulphur up to 10 points, as illustrated by Figs. 1 to 6 and summarized in Table II.

In all cases the tensile strength decreases slightly and uniformly with increasing sulphur. In nearly all cases the yield point increases slightly with increasing sulphur. These tendencies are markedly accentuated by quenching.

Curves for reduction of area always show a maximum at 0.04 to 0.06 per cent S, much more pronounced in the transverse specimens. (This might bear out the contention of certain steel makers that it is more damaging to "force" a heat of steel to remove sulphur than to leave it in, were it not for the fact that the manganese curve shows a definite minimum in the same region.) Heat-treatment has a singularly small effect on reduction of area.

TABLE III—IMPACT TESTS

	1-In. Rivet Bar; Broken Across the Fiber			5½x1-In. Flats, Broken With the Fiber Impact Parallel to Rolling			Impact Perpendicular to Rolling		
As received	0.03S	0.06S	0.10S	0.03S	0.06S	0.10S	0.03S	0.06S	0.10S

Impact shear	50	47	41	50	46	41	47	45	42

Sulphur content up to 0.10 per cent seems to have little influence on elongation.

Impact Strengths

A maximum just noted in the curves for reduction in area reappears more pronouncedly in the curves for Izod and Charpy impact on rivet bars tested in the condition as received, Fig. 7. In these curves for the first time appears an unmistakable deterioration in properties when sulphur goes above 0.06 per cent. Minor fluctuations are generally paralleled each to each, in Izod and Charpy tests. Impact shear[1] on an unnotched specimen, on the other hand, is quite straight, and almost horizontal.

Ambiguous wording in Figs. 10 to 12 referring to the direction of fracture on transverse tests may be removed by a glance at Fig. 13. All transverse impact fractures are therefore fractures "with the fiber." Comparing the curves for impact shear, it appears immaterial whether an *unnotched* specimen is broken with or across the direction of rolling—the work expended is substantially the same. (It may be debatable whether such results, in view of wide variations in notched bars broken in Charpy and Izod machines, denote a uniform material or an insensitive testing method.) Charpy tests transverse and "with impact in direction of long dimension of slab" break with less than half the work it requires for rivet bars, and the effect of high sulphur is even more apparent than before, dropping from 26 ft.-lb. for 0.03 S to 16 ft.-lb. for 0.10 S.

Annealing Destroys Impact Properties

Extraordinary variation in Izod impact values is shown after annealing rivet bars 30 minutes at 940 deg. C. and cooling in the furnace. Heats A and H, whose other properties do not vary widely, have Izod impacts of 26 and 47 respectively, while E and D, whose chemical composition except for manganese is almost identical, give results of 34 and 66. These are the average of eight tests. Charpy impact results are much more regular, but are surprisingly low—about 10 ft.-lb. —and apparently unaffected by sulphur. Impact shear, as before, is featureless and quite steady at about 38 ft.-lb.

Charpy tests on annealed flats are confused and not consistent. It seems that annealing reverses the relative impact strengths, when hit on the sawed cross-section or on the flat surface, from that shown in the bars as received.

Quenched rivet bars give Charpy and impact shear

[1]Method described by D. J. McAdam, Jr., *Proceedings*, A.S.T.M., vol. 16, Part II, p. 299 (1916).

values somewhat higher than the bar as received, and the bad effect of high sulphur is accentuated by quick cooling, as was the case in the tensile properties. Izod figures are quite erratic, as before, but eliminating the high-manganese, high-carbon heat F, the impact value of quenched bars containing up to 0.06 per cent sulphur remains reasonably constant at a little over 110 ft.-lb., whereupon it takes a sharp drop. Transverse tests on quenched flats are very confusing.

In review, it may be said that the effect of sulphur is unmistakably and strongly felt on the impact strength of rivet steel. Even one who pins his faith in the shearing strength of unnotched bars will recognize a definite if sometimes slight downward slope of all the curves with increasing sulphur content. Despite the violent fluctuations of some of the values for quenched specimens the Charpy and Izod tests magnify this downward tendency to a very marked extent. It

may be contrary to expectation to find low impact strength in annealed bars and high impact strength in quenched bars. Unfortunately no metallographic studies are yet available to indicate whether or not low impact strength is associated with immoderate grain growth.

Hardness

Sulphur has practically no effect on the hardness, as is seen in Fig. 14 and Table IV. A slight trough in the curves at 0.04 to 0.06 per cent S is probably due to

low contents of manganese, since the hardness curves parallel the amount of manganese in the samples fairly closely. It is rather remarkable that the steels delivered to Annapolis are consistently and substantially harder than those sent to Watertown (an average difference of 11 Brinell units is recorded in the bars as received).

Torsion

Torsional properties of 1-in. rivet bars are very slightly affected by sulphur up to 0.10, if at all. (See Table V.) Properties are satisfactorily approximated by a straight line, nearly horizontal. Curves for "angle of twist at break" are so jagged that it would be unsafe to draw many conclusions from the pronounced bump at 0.05 to 0.06 per cent sulphur; in fact a smoother

curve may be had by plotting against manganese content rather than against sulphur.

Static Shear of Rivets and Riveted Joints

In view of the use to which rivets are ordinarily put in structures of magnitude, especial attention should be given to the tests on shearing strength of rivet bars and riveted joints, shown by the committee in Fig. 15, and summarized by the writer in Table VI. Single-shear joints were made by riveting $\frac{5}{8}$-in. chromium-nickel steel plates with rivets from each heat, and then pulled apart in a testing machine; sixteen tests from each heat were made. Similarly ten tests from each heat were made on double-shear joints. None of these joints is sketched in the preprint.

As shown by the curves in Fig. 15, the shearing

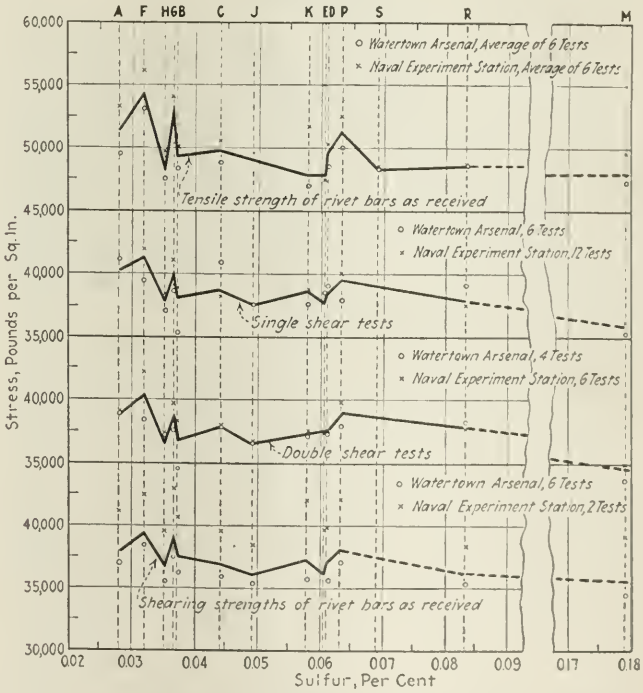

FIG. 15—SHEARING TESTS ON RIVETED JOINTS IN SINGLE AND DOUBLE SHEAR, AND ON THE RIVET BARS AS RECEIVED

strength of the rivet bar as received is almost exactly parallel to those derived from riveted joints. It appears therefore that the normal processes of making and driving a $\frac{15}{16}$-in. rivet does not materially alter the properties as determined in the original bar, as far as shearing strength in the completed joint is concerned, when tested under static loads. We may conclude that:

The static strength of rivets in single- or double-shear is closely approximated by the shearing strength of the rivet bar, and equals 38,200 lb. per sq.in. for basic open-hearth steel containing 0.11 C, 0.43 Mn, 0.01 P and 0.03 S. Each 0.01 per cent sulphur decreases this value 300 lb. per sq.in.

Conclusion

About the only recommendation the committee made in this preliminary report is that a comparative study of the various curves might be useful. Following that suggestion, I have taken the liberty of adding the curve for tensile strength of the rivet bars as received to Fig. 15. It shows that whatever may be the various factors which cause one of these steels to be slightly different from another, they seem to have a net effect on the tensile test, as they have on a rivet driven tightly in place. As far as the static properties of rivet steel are concerned the tensile strength gives as much information as any of the others.

Impact properties, measuring toughness, assuredly should be high in a rivet. Much debate may be had from proponents of certain impact machines, and from opponents of all of them. However that may be, the present series of rivet bars is so balanced in chemical composition, manufacture and treatment that the impact values are not materially lowered until sulphur passes 0.06 per cent. Indeed, indiscreet heating may do ten times as much damage as 0.10 per cent sulphur.

The maximum sulphur now allowed in structural steel rivets (0.045 per cent) is at least 0.01 per cent below the point where sulphur will damage the strength of a well-made rivet steel, as far as its performance can be predicted by known tests.

Crystal Structures of Vanadium, Germanium and Graphite

Albert W. Hull, of the Research Laboratory, General Electric Co., read a paper on the above subject before the recent meeting of the Physical Society at Washington. Vanadium has been analyzed in powdered form by the X-ray diffraction photograph method. Its lattice is a body-centered cube with side 3.04 Angstrom units. The distance between nearest atoms is 2.63 Angstrom units, and the ideal density 5.96.

Germanium is found to have a crystal structure the same as that of diamond. The side of the unit cube is 5.63 Angstrom units, the distance between nearest atoms 1.218 Angstrom units, and the density 5.36.

New and more accurate diffraction patterns of graphite have confirmed the structure described in an earlier paper—viz., a lattice of the hexagonal close-packed type. The measurements cannot be reconciled with the rhombohedral structure found by Debye. The exact distance between nearest planes cannot yet be stated with certainty. Measurements are in progress which, it is hoped, will determine this distance, and whether the three bonds are all in one plane, with the fourth bond at right angles, or whether all four bonds are symmetrically disposed as in diamond.

Production of Platinum and Allied Metals in 1921

Miners report to the United States Geological Survey a production of 538 troy ounces of crude platinum in 1921, distributed by states as follows: California, 387 oz.; Oregon, 83 oz.; Alaska, 65 oz. Refiners report the purchase of domestic crude platinum in the following quantities by states: California, 847 oz.; Oregon, 96 oz.; Alaska, 78 oz. They also report the purchase of 56,654 oz. of foreign crude platinum, of which 55,286 oz. was from Colombia, South America; 63 oz. from Canada, and 1,286 oz. of Russian origin.

Refiners report an increase of over 26 per cent in the recovery of new platinum metals in 1921, as compared with 1920. The greatest increase was in platinum. Of the metals recovered in 1921 by refiners, about 4,800 oz. was obtained from domestic material.

NEW PLATINUM METALS RECOVERED BY REFINERS, IN TROY OUNCES

	Platinum	Palladium	Iridium	Osmiridium	Other	Total
1917	33,009	4,779	210	833	.....	38,831
1918	54,399	4,024	465	539	326	59,753

Studies in the Carbonization of Coal: The Mechanism of Coal Carbonization*

Critical Review of Current Theories of Secondary Carbonization Reactions — Interpretation of the Mechanism of Coal Carbonization in the Light of the Composition of a Commercial Low-Temperature Tar — A Theory of the Constitution of Coal

BY JEROME J. MORGAN AND ROLAND P. SOULE
Department of Chemical Engineering, Columbia University, New York City

IN A previous contribution a scheme was outlined for the ready examination of low-temperature coal tar, and by its means the characteristics of a commercial product were determined. Comparison with the composition of low-temperature tars produced on a small scale shows that the commercial tar represents a slightly more advanced stage of carbonization. It is thus possible in the present paper to present a new viewpoint on the much-disputed mechanism of the carbonization of coal, and to interpret distillation reactions in the light of the composition of this intermediate product. Finally, there is proposed briefly a theory of the constitution of coal which explains the composition of low-temperature tars.

Berthelot's classic theory[34] of the origin of ordinary coal tar held the field for many years after it was first advanced in 1866. Acetylene is formed, Berthelot stated, by the decomposition of such simple gases as methane in the volatile products from coal, and polymerizes immediately at high temperatures to form benzene, styrolene, naphthalene and other aromatic hydrocarbons. This theory has been rendered untenable, however, by experiments which have proved (1) that acetylene is not formed in any considerable quantity in the gaseous products of coal distilled at various temperatures, and that its reaction velocity of synthesis is not fast enough to account for this absence;[35] (3) that methane, ethane and propane do not yield acetylene as their principal decomposition products;[36] and (3) that primary distillation products of relatively high molecular weight—i.e., low-temperature tars—are obtained in the carbonization of coal.

All modern theories of carbonization, therefore, acknowledge the important rôle played by low-temperature tars in the distillation of coal. While it is thus generally recognized that ordinary high-temperature (900-1,200 deg. C.) coal tar is formed by the decomposition of tar produced at lower temperatures (500-600 deg. C.), the mechanism of this decomposition[37] is still a matter of lively dispute. No comprehensive scheme has been advanced to account for more than relatively a small number of carbonization phenomena. Investigators in general have confined themselves to limited aspects of the problem, and have sought to lay emphasis upon certain predominating reactions. Thus, the origin of the aromatic hydrocarbons of ordinary tar has been variously attributed to:

(1) Decomposition of the hydrocarbons of low-temperature tar to simple compounds, which subsequently undergo pyrogenetic syntheses (Jones, Bone, *et al.*).

(2) Hydrogenation and dealkylation of the phenols of low-temperature tar (Schulze, Fischer and Schrader).

(3) Dehydrogenation and dealkylation of the unsaturated hydrocarbons of low-temperature tar (Pictet).

The present investigation leads to evidence which supports in general the last two of these conceptions, and hence assigns to pyrogenetic syntheses a part of secondary importance. A brief review of the experimental data underlying these several carbonization theories is a necessary preliminary to the development of a more comprehensive and extended analysis of the phenomena of coal distillation.

THEORIES OF DECOMPOSITION OF LOW-TEMPERATURE HYDROCARBONS

Pyrogenetic Syntheses. Probably the most generally accepted theories of tar formation at present are those which postulate the decomposition of the primary tar to simple unsaturated hydrocarbons that condense subsequently to form aromatic hydrocarbons. Jones[38] states that "the mechanism of the breaking down of low-temperature tar consists essentially in the decomposition of the naphthenes, paraffines and unsaturated hydrocarbons present in the low-temperature tar to form olefines of varying carbon content, which condense at higher temperatures to aromatic substances."

In arriving at this conclusion he passed low-temperature tar[39] slowly through a tube filled with porous porcelain, and examined the gaseous products obtained at various temperatures between 550 and 800 deg. C. He stated that benzenoid hydrocarbons could be formed only to a limited extent[40] by the elimination of hydrogen from the corresponding naphthenes, since members of the cyclohexane series break down principally by a scission of the ring with the formation of olefines, including butadiene, and of paraffines and hydrogen. The gaseous olefines were found to be at a maximum at 550 deg., and almost disappeared at 750 deg. This

disappearance synchronized with the appearance of naphthalene, and immediately preceded a rapid increase in the evolution of hydrogen, which "must probably be attributed to the union of the aromatic molecules and to intramolecular ring closing."

Jones quotes the work of Staudinger[41] as an example of the polymerization of diolefines to aromatic substances. Moreover, Staudinger identified butadiene in the gas distilled from coal. Instances of its formation also from naphthenes, olefines, saturated hydrocarbons and petroleum vapors from cracking stills are also cited. "It is highly probable," Jones concludes, "that a necessary transition stage is the formation and condensation of olefines containing the conjugated double linkage —CH: CH. CH: CH— . Polynuclear aromatic substances are formed at 750 deg. and upward subsequent to the decomposition of the olefines." Jones, contrary to Pictet, regards phenols as primary products of coal distillation, "those of high-temperature tar being formed with certain changes from those of low-temperature tar. Much of the high-temperature pitch is formed by partial carbonization of the low-temperature pitch."

Bone,[42] from a study[43] of the behavior of the simple hydrocarbons at temperatures between 500 and 1,200 deg. C., has elaborated this theory of olefine condensations. He introduces the new conception that the thermal decomposition of the hydrocarbons of low-temperature tar "involves the *primary* formation by dehydrogenation of the unsaturated residues CH_2 (two free bonds) and CH (three free bonds), which during a fugitive but really independent existence are free to interact with the surrounding gaseous medium after their kind." Bone points out that the most favorable temperature range for aromatic formations from such residues (500-800 deg.) coincides with that giving the best yields of benzene and its homologs and is well below that which is most favorable to the hydrogenation of the residues to methane. Between 500 and 800 deg. "ethylene is, by reason of its rapid production of CH residues (three free bonds) during its primary decomposition, eminently capable of generating aromatic nuclei, although to a less marked degree than in the case of acetylene. On the other hand, ethane, which primarily produces CH_2 residues (two free bonds) only, does not form aromatic nuclei so readily as does ethylene."

Another variation of the olefine theory is advocated by Whitaker and Crowell,[44] who distilled coal in 5-lb. charges at different temperatures, and examined the liquid and gaseous products of carbonization. They suggest that the course of reactions in coal carbonization is as follows: "Solid coal→high molecular weight paraffines→low molecular weight paraffines; olefines→ acetylenes, naphthenes and polycyclic compounds→ benzene and its homologs→higher homologs of benzene →xylene→toluene→benzene, etc." Attention was directed to the apparent marked similarity between this series of decompositions and those postulated[45] for oil cracking. A somewhat similar sequence of coal reactions has recently been advanced by Wigersma.[46]

Theory of the Decomposition of Low-Temperature Phenols

The investigators whose work has been reviewed thus far have paid scant attention to the rôle of the phenols in secondary decompositions. In 1885 Schulze,[47] on the occasion of his pioneer investigation of the naphthols of ordinary coal tar, stated that coal is essentially altered cellulose and that its primary decomposition products are the phenols. The phenols on further heating (1) eliminate water to synthesize high-boiling hydrocarbons; (2) are partly reduced to low-boiling hydrocarbons; (3) are decomposed to form gases; or (4) escape unchanged. These reactions were conceived as progressing simultaneously and in equilibrium with each other. So strong was the influence of Berthelot's theory at that time, however, that Schulze made his propositions simply to supplement rather than to displace the acetylene hypothesis.

Very recently Fischer and Schrader[48] have also assigned to the phenols a part of major importance. They point out that low-temperature tars consist essentially of hydrocarbons similar to those of petroleum and of phenols, but contain no aromatic hydrocarbons. The benzene homologs in high-temperature coal tar must be formed from these phenols, they conclude, since the hydrocarbons can be converted into aromatics only to a slight extent. In support of this view experiments are cited on the decomposition of cresols and xylenols when passed through tinned tubes heated to 750 deg. in an atmosphere of hydrogen. The phenols were reduced to benzene homologs, and these in turn yielded some benzene. Thus, according to these authors' theories of the decomposition of low-temperature tar in coal carbonization, the aliphatic hydrocarbons are broken down into gases, while the hydroaromatic hydrocarbons are in part dehydrogenated and in part changed into gaseous hydrocarbons. A small portion of the phenols of the low-temperature tar remain unchanged, but most of them are reduced to such stable hydrocarbons as benzene, or take part in syntheses of napthalene, anthracene and other aromatics.

Theory of Dehydrogenation and Dealkylation

Pictet[49] passed "vacuum tar" through a red-hot tube filled with pieces of coke, and obtained the typical products of high-temperature distillation. He concluded that the hydroaromatic hydrocarbons of vacuum tar underwent dehydrogenation and detachment of side-chains to yield aromatic hydrocarbons and the large quantity of hydrogen and methane homologs characteristic of high-temperature gases. This theory is supported by the known tendency of aromatic hydrides to lose a part of their hydrogen, by the occasional presence in ordinary tar of small quantities of hydroaromatic hydrocarbons, and by the fact that the cracking of naphthenic petrols yields a certain quantity of aromatic hydrocarbons. Since cyclohexane on cracking yields little benzene, and tends rather to break the ring with the formation of unsaturated aliphatic compounds, the cyclanes of coal, Pictet states, cannot have

contributed largely to the formation of benzene and its homologs.

It is the unsaturated cyclic hydrocarbons, he argues, which are present in much larger quantity, and which are hence the principal source of the benzene hydrocarbons of ordinary tar. Certain of the polycyclic hydrocarbons, such as fluorene, also owe their existence to simple dehydrogenation, since hexahydrofluorene was found in "vacuum tar." The origin of naphthalene and anthracene was regarded as still obscure, however, since no hydrogenated derivative of either of these was found in "vacuum tar" or in the benzene extract of coal.

Limitations of Experimental Methods in Carbonization Studies

It is desired to call attention at this point to certain conditions which complicate the study of carbonization reactions. Aside from such factors of prime importance as temperature and pressure, the course which these reactions take depends upon the relative concentrations of the reacting substances, and hence the nature of the coal carbonized, and upon the path of travel of the gases in the oven.[50]

Coals of oxygen content lower than normally used in commercial carbonization practice have been employed by some observers, who consequently lost sight of the effect which the higher phenol concentration would have in the formation of the typical aromatic hydrocarbons of ordinary tar. Carbonization reactions occur simultaneously, and represent complex equilibria, the individual factors of which are difficult to divorce from one another for separate investigation. When experiments on the decomposition of isolated hydrocarbons are quoted, translation of such results to commercial conditions is obviously open to question. The strongly reducing atmosphere of coke ovens and gas retorts is a factor that too often has been ignored in pyrogenetic assumptions. Thus it has been shown[51] that at 550 deg. benzene in an atmosphere of nitrogen readily loses hydrogen with the formation of diphenyl, but in the presence of an excess of hydrogen yields only traces of diphenyl. Toluene carried through coke in a stream of nitrogen at 750 deg. yields naphthalene, anthracene and a viscous black liquid. On the other hand, the substitution of hydrogen for nitrogen greatly accelerates the decomposition of the toluene, and produces large amounts of benzene and only a small quantity of solid condensate.

Attention is directed also to the difference in the results obtained in small-scale experiments and in commercial operation. For example, when 2-g. samples of coal are distilled[52] under a high vacuum in a platinum tube, there is obtained a maximum yield of tar at 750 deg., which is nearly four times that recovered at 450 deg. It is a well-known fact, on the other hand, that the yield of low-temperature tars on a commercial scale is about double that of ordinary high-temperature tars.

Again, Jones[38] decomposed 0.1-g. samples of low-temperature tar in a glass tube filled with porous porcelain, and based much of his theory of carbonization reactions on the analysis of the gases obtained at different temperatures. If comparison is made of these results with the gas analyses of Thau,[53] who distilled coal in a commercial coke oven over the same range of temperatures, striking differences are at once manifest. The sudden increases in the evolution of hydrogen and of methane synchronizing with the disappearance of olefines and the appearance of aromatics noted by Jones is not apparent in the coke-oven analyses. As an example of the influence of retorting conditions, Thau found as a result of superheating the upper part of his coke oven that the hot surfaces of carbon were much more effective in causing decomposition than were the retort walls.

Interpretation of Carbonization Reactions in Terms of the Present Investigation

The low-temperature tar studied in the present investigation represents a stage of carbonization slightly more advanced than that which gave rise to the vacuum tars investigated by Pictet and by Jones and Wheeler. It was produced by the Carbocoal process[54] in a commercial retort that afforded an opportunity for secondary reactions to take place to a limited extent. Thus the distillation vapors came into contact with the retort shell heated to about 600 deg., and yielded a product that is distinguished from these true low-temperature tars by (1) a slight decrease in the quantity of total phenols and a marked increase in the proportion of low-boiling phenols; (2) the appearance of a large percentage of tertiary nitrogen bases; and (3) a notable increase in the ratio of unsaturated to saturated hydrocarbons.

The Decomposition of Low-Temperature Phenols During Carbonization

A true low-temperature tar contains about ten times the quantity of phenols that appears ultimately in the high-temperature tar. Thus, a 30 per cent volatile coal produces a primary tar containing about one-quarter its weight of phenols, and yields in the coke oven about half this weight of tar containing less than 5 per cent of phenols. The low-temperature phenols consist principally of the higher homologs. High-temperature phenols, on the other hand, contain about two parts of cresols to one of phenol, together with a relatively insignificant proportion of higher-boiling tar-acids. It is thus apparent that while the phenolic components of the primary tar contribute very largely to the formation of secondary products, only a small part of them survive as phenols, and then chiefly as the first members of the series.

The low-temperature phenols, as would be expected, occupy a position intermediate between the extreme low-temperature type and the phenols of ordinary tar. The phenols obtained[55] by steam distillation of a Lohberg gas coal at a temperature slightly lower than that in the case of the low-temperature phenols exceeded the latter in total quantity. The fraction of Lohberg phenols distilling below 230 deg. constituted only 7 per cent of the total weight, while the corresponding fraction of low-temperature phenols amounted to 57 per cent. It thus becomes evident that the first stage in the decomposition of the primary phenols is one which involves principally the elimination of the multiple short sidechains of the higher homologs. This reaction

is probably accomplished by the replacement of the methyl or ethyl groups by hydrogen from the retort gases, with the formation of methane or ethane.

Again, when low-temperature phenols are passed through a tinned tube at 750 deg. in an atmosphere of hydrogen, there are obtained[48] low-boiling phenols and hydrocarbons, together with water. Higher temperatures, therefore, must eliminate the hydroxyl groups also, and the predominating reaction then becomes hydrogenation with the production of water. Moreover, cresol when passed over coke at 750 deg. in a stream of hydrogen yields benzene and toluene.[51]

The present investigation has shown that the low-temperature phenols contain about 10 per cent of naphthol derivatives. The hydrogenation of these with elimination of water is obviously one source of the naphthalene of high-temperature tar.

If the decomposition of the primary, monocyclic phenols were confined to such hydrogenation reactions, however, there would result in high-temperature tar a much higher yield of light oils and solvent naphtha than is actually the case. Experiment has shown[51] that monocyclic aromatic hydrocarbons also undergo the same reaction—e.g., xylene is converted into toluene, and toluene is converted into benzene, with the simultaneous formation of a small amount of solid condensate. Thus it was found[44] that the temperatures of maximum formation of xylene, toluene and benzene are respectively 600, 700 and 800 deg., and that the total quantity of light oil formed decreases steadily as the temperature of carbonization is increased above 500 deg. The limited quantity of benzene itself occurring in high-temperature tar, however, makes it necessary to conclude that in addition to the reactions enumerated, a portion of the benzene participates in pyrogenetic syntheses. It is possible also that some of the phenols sustain scission of the ring and are lost from the tar as gases, or, as Fischer and Schrader[48] suggest, condense to form polycyclic aromatic hydrocarbons. However this may be, it is nevertheless evident that the phenols are the chief source of the monocyclic aromatic hydrocarbons.

The Decomposition of the Nitrogen Bases During Carbonization

Since a considerable quantity of the nitrogen bases of low-temperature tars remains after distillation in the pitch, it is difficult to determine whether the total quantity is greater or less than in ordinary tar. It was found,[56] however, that the percentage of bases (3.42 per cent) boiling under 326 deg. in a mixture of coke-oven and gas-works tar was nearly double that (1.94 per cent) of the low-temperature tar. It is probable, therefore, that low-boiling bases are formed from high-boiling bases in a manner analogous to the decomposition of the high-boiling phenols.

Pictet's suggestion[49] that quinoline is formed from dihydroquinoline by simple dehydrogenation seems to be the most rational explanation of the primary decompositions of the low-temperature bases. Secondary bases of the type of dihydroquinoline are found in "vacuum tar," but tertiary bases are absent. The fact that 80 per cent of the low-temperature bases and almost all of the high-temperature bases are tertiary compounds supports this theory of dehydrogenation.

Experiments with the low-temperature bases demonstrated the presence of unsaturated bases, the relative molecular weights[57] of which average 10 to 15 higher (Fig. 12) than the values of the corresponding high-temperature compounds. At higher temperatures (700 to 800 deg.), therefore, a process of combined dehydrogenation and dealkylation must take place to yield the ordinary bases such as quinoline and acridine. Moreover, the toluidines described by Pictet then yield the aniline of ordinary tar just as it has been shown that cresol yields phenol, and toluene yields benzene.

The low-temperature distillate was shown to contain no preponderating base, but to represent a series of

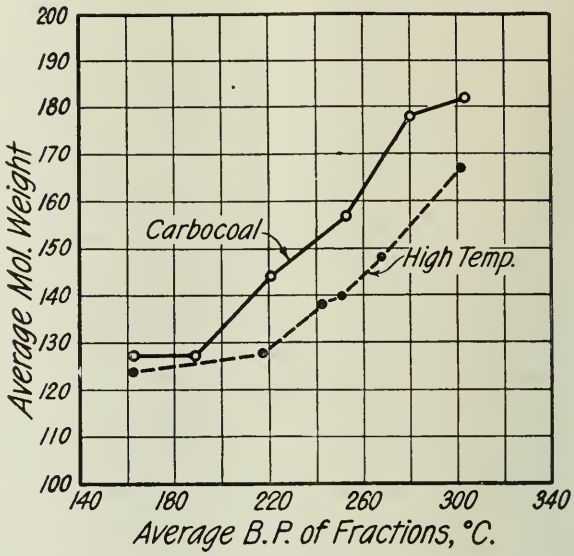

FIG. 12—AVERAGE MOLECULAR WEIGHTS OF BASES

compounds of increasing molecular weight. The distillation curves of Fig. 13 emphasize the preponderance of quinoline in the high-temperature bases, and indicate, if this theory is accepted, that the bulk of the middle-boiling bases of low-temperature tar are structural derivatives of quinoline, and yield this compound upon decomposition at the temperature of the coke oven. The physical constants obtained are consistent with this observation, and dehydroquinoline has been identified in "vacuum tar."

The Decomposition of the Hydrocarbons During Carbonization

The ratio of saturated to unsaturated hydrocarbons is highest in the tars produced under high vacuum at the lowest temperatures. Thus the saturated hydrocarbons obtained by Jones and Wheeler were about equal in quantity to the non-saturated, while in low-temperature tar they formed only one-third of the distillate and a much smaller fraction of the entire tar. The obvious conclusion, therefore, is that the initial decomposition of the primary hydrocarbons is characterized by a partial dehydrogenation of the naphthenes to form hydroaromatics.

As mentioned above, Jones[40] was led to believe from his experience in the decomposition of cyclohexane, methylcyclohexane and the di- and tetrahydro-derivatives of naphthalene that the naphthenes cannot be regarded as the direct source of the high-temperature aromatic hydrocarbons through simple dehydrogena-

[44] See first paper in this series.

[57] Only relative values are given by the ordinary Beckmann cryoscopic method, since nitrogen bases are slightly associated in benzene solution.

tion and dealkylation. The large yields obtained of both the corresponding aromatic hydrocarbon and hydrogen were explained on the basis that "the most probable course of the reaction would be for the cyclohexane first to lose two atoms of hydrogen and form cyclohexene, which then decomposes in two ways, yielding benzene and butadiene." The principal reaction and the one contributing most largely to aromatic formation was held to be the condensation of such conjugated unsaturated nuclei as the butadiene represents. These nuclei are stated to result in the distillation of coal from the decomposition of the paraffines, the naphthenes and the unsaturated hydrocarbons of low-temperature tar.

Results in the low-temperature investigation, on the contrary, lead to the contention that while the elimination of hydrogen from the naphthenes of the primary low-temperature tar is the initial step in the decomposition reactions, the intermediate di- and tetra-hydroderivatives thus formed constitute a distinct and comparatively stable stage in the carbonization of coal. Consistent with his theory Jones considered these compounds to be partly olefinic. Pictet, on the other hand, identified them as unsaturated naphthenes, and advanced the rational hypothesis that the origin of the aromatics lay in a process of dehydrogenation of the aromatic hydrides and of detachment of sidechains from alkyl derivatives. The composition of the low-temperature hydrocarbons has been shown[56] to conform with this hypothesis of Pictet and to be consistent with all the experimental facts upon which Jones bases his interpretation.

The Origin of Naphthalene in Coal Tars

The bulk of the unsaturated hydrocarbons of low-temperature tars are polycyclic. While some of the naphthalene of ordinary tar results from the hydro-

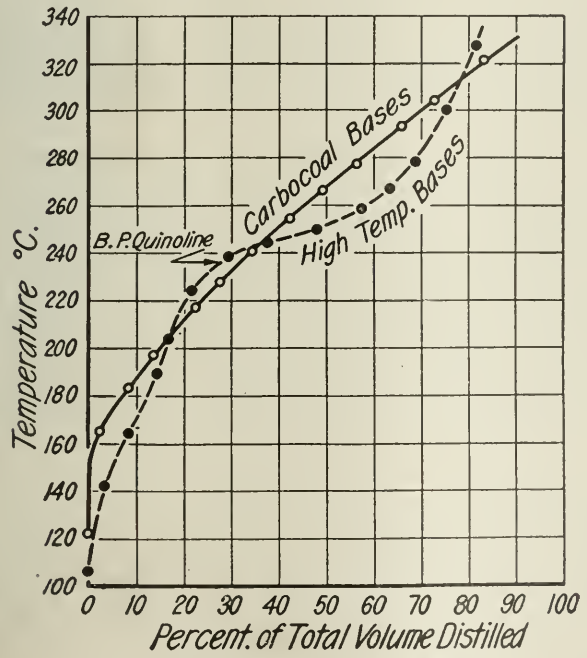

FIG. 13—DISTILLATION OF BASES

genation of naphthols, it is believed that the naphthalene and other polynuclear aromatic hydrocarbons owe their origin chiefly to the decomposition of these polycyclic unsaturated compounds. The presence of a series of homologs of hydrogenated and alkylated bicyclic hydrocarbons is indicated in low-temperature tar by the physical and chemical properties. For example, the average molecular weights[58] of the middle-boiling fractions (Fig. 14) are notably higher than that of naphthalene. Fig. 15 shows that the secondary reactions giving rise to high-temperature tar decompose these bicyclic hydrocarbons to the single stable naph-

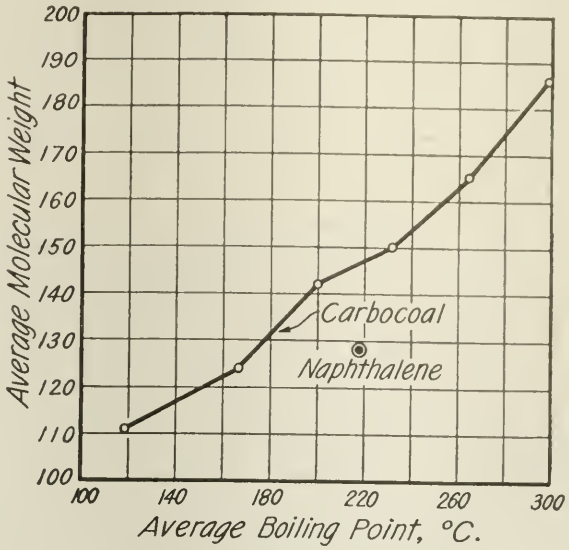

FIG. 14—MOLECULAR WEIGHTS OF NON-SATURATED HYDROCARBONS

thalene nucleus, the presence of which in large quantity is one of the outstanding features of ordinary tar. The analogy between naphthalene and quinoline in chemical structure makes more striking the similarity between the carbonization reactions of the hydrocarbons and nitrogen bases.

A Theory of the Cyclic Structure of Coal

Probably the most remarkable general characteristic of low-temperature tars is the fact that they are almost entirely cyclic in nature. So far as the various compounds have been identified, moreover, these cycles have shown themselves to be six-membered rings or combinations of six-membered rings. This structural characteristic apparently persists in the tar as the temperature of distillation of the coal is increased.

It seems reasonable, therefore, in view of the great stability of the six-membered ring, to ask if this structure is not characteristic also of the coal substance itself. Such a conception is contrary, of course, to the widely accepted cellulose-furane theory.[59] Fischer and Schrader[60] have recently stated that the plant cellulose is destroyed by bacterial activity in the early stages of peat formation, and pointed out, moreover, that while cellulose yields on decomposition almost exclusively phenol itself, low-temperature tars contain chiefly the higher homologs of phenol. In the absence of cellulose the lignin must hence be the source of the phenols of coal tar.

The cyclic structure of lignin has been advocated by these authors, who assign to it an aromatic configura-

tion with acetyl and methoxyl groups. During coal formation the methoxyl content must eventually decrease through saponification, reduction or replacement by hydroxyl groups. In any case there results a phenol, which is considered identical with humic acid. Oxidation or polymerization of humic acid forms the alkali-insoluble humin. Further splitting off of water, carbon dioxide and perhaps methane at ordinary temperature, these authors argue, leads to lignite and coal. The whole series is thus assumed to perpetuate the aromatic structure of lignin. The production of large amounts of mellitic acid by the pressure oxidation of charcoal and ordinary coals (but not of cellulose) is contributory evidence of the presence of six-membered cycles in coal.

The present investigation leads to the suggestion, therefore, that the chemical properties of coal may be represented by a structure containing many such cycles. This structure may be pictured as an aggregate of "mosaics" of these rings. Some of the "mosaics" contain oxygen, and display the insolubility characteristic of the "cellulosic degradation products,"[59] or, according to Fischer and Schrader, the "lignin degradation products." These may be regarded as polymerized phenols, as suggested above, or as multi-molecular structures in which component rings are joined together by oxygen-containing bridges. Heating results in the breaking of these bridges with the formation of high-boiling phenols, the sidechains of which are remnants of other broken linkages.

Similarly, other "mosaics" may be pictured to represent the same typical rings held together by bridges of paraffine hydrocarbons, the breaking or detachment

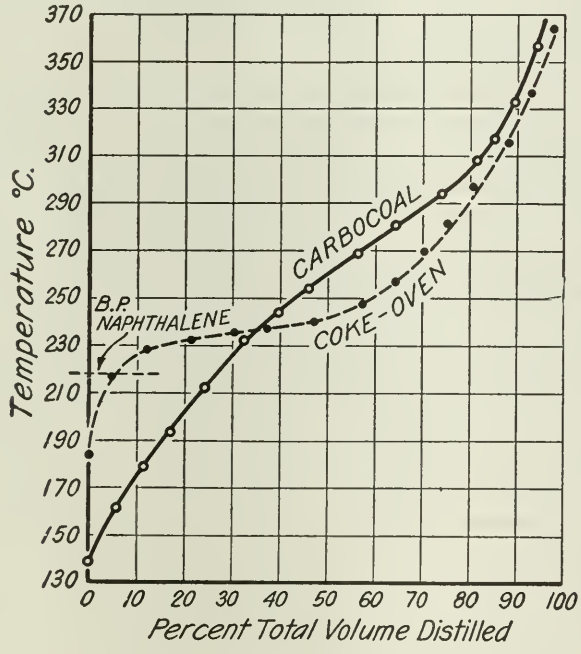

FIG. 15—DISTILLATION OF HYDROCARBONS

of which are responsible for the presence of straight-chain hydrocarbons in low-temperature tars,[61] or even in seams of the coal deposits themselves. These structures are more soluble, and have been called the "resinous constituents."[59] Nitrogen and sulphur compounds may be regarded as appearing in strictly analogous configurations.

[61] *Cf.* the "bound molecules" of Jones and Wheeler (Ref. 59).

Summary of the Mechanism of Coal Carbonization

(1) The decomposition of the coal substance to ordinary high-temperature tar when subjected to the action of heat is a process of progressive, step-by-step decomposition, in which pyrogenetic syntheses play only a secondary part.

(2) Six-membered rings and combinations thereof characterize the entire series of decomposition products from coal to high-temperature tar. The decompositions during carbonization are essentially reactions effecting the elimination of sidechains.

(3) The average molecular weights of the liquid intermediate products constantly decrease as the temperature of carbonization rises. This decrease is marked by the evolution of hydrogen, methane and ethane.

(4) The initial decomposition of the low-temperature tar first formed is brought about by (*a*) loss of hydrogen from a portion of the naphthenes with a resultant increase in the proportion of unsaturated hydrocarbons; (*b*) loss of sidechains from the phenols by hydrogenation with the resultant formation of lower-boiling phenols; and (*c*) loss of hydrogen from the nitrogen bases to form a large proportion of tertiary compounds. (This stage is represented by Carbocoal tar.)

(5) Final decompositions are at a maximum between 700 and 800 deg., and are marked by (*a*) dehydrogenation and dealkylation of the hydroaromatic unsaturated hydrocarbons and nitrogen bases to form aromatics, with the elimination of hydrogen, methane and other simple gases; (*b*) hydrogenation of the phenols to aromatic hydrocarbons and of these aromatic hydrocarbons to lower-boiling aromatics, with the formation of methane, ethane and water; and (*c*) secondary pyrogenetic syntheses of higher aromatics from simple compounds.

(6) The phenols of low-temperature tar are the principal source of the monocyclic aromatic hydrocarbons. The unsaturated naphthenes of low-temperature tar are the principal source of the polycyclic aromatic hydrocarbons.

Status of Steel Industry in South Africa

Up to the close of the year 1921 the exhaustive plans of the South African Iron & Steel Corporation had not yet materialized and the productive equipment had not reached beyond that acquired from the Pretoria Iron Works, says a special report to the Iron and Steel Division of the Department of Commerce, from Consul Pisar, Cape Town. Over two-thirds of the authorized capital of £1,500,000 remained unsubscribed, and in view of the depression prevailing at present throughout South Africa there appears to be little hope that the great iron and steel industry planned by the promoters will become a reality in the very near future. Efforts to get capital in other countries have not been successful. Quite recently the corporation's properties were visited by English steel experts who expressed themselves as favorably impressed with the prospects of this venture. Until economic conditions throughout the world become stabilized and the corporation can obtain the necessary capital and produce steel on a competitive basis, no material results can be expected.

The operations of all the steel mills in South Africa resulted in a production of 21,988 tons of steel goods in 1921. The industry gave employment to an average number of 285 white men and 866 colored laborers.

Application of Electrical Precipitation to the Wood-Distillation Process*

Tests on Experimental Wood-Distillation Retort Indicate the Possibility of Precipitating the Tar From the Hot Vapors by Means of a Cottrell Precipitator, Thus Reducing the Amount of Soluble Tar in the Pyroligneous Acid to a Point Where Direct Neutralization Is Feasible

By L. F. HAWLEY† and H. M. PIER‡

IN THE commercial distillation of hardwood for the preparation of wood alcohol and acetate of lime the first operation after the distillation of the wood and the condensation of the liquid products consists in the distillation of the pyroligneous acid for the purpose of separating the tar which is dissolved in the acid. The distilled acid is then neutralized with lime, distilled to remove the alcohol, and evaporated in order to obtain the acetate of lime. If the pyroligneous acid were not distilled before neutralizing with lime, much of the tar in solution in the crude acid would stay in solution after neutralization and, therefore, contaminate the acetate of lime. The so-called dissolved tar which is removed from the pyroligneous acid by distilling off the acid is not a tar like the settled tar consisting of oils and pitch, but is really a pitch containing very small proportions of oil, soluble in the pyroligneous acid on account of the presence of acetic acid and methanol.

Preventing Formation of Soluble Tar

Since this contaminating pitch or tar is non-volatile, it must be carried over from the retort to the condenser in the form of a fog or mist consisting of very fine drops of liquid pitch. Attempts have been made to prevent this pitch from reaching the condenser by interposing baffle plates and other mechanical devices between the retort and the condenser, but without success.

Since the Cottrell precipitator is able to precipitate fine particles of liquid or solid when carried in a stream of gas or vapor, it was thought that it could stop the non-volatile portion of the wood distillate before it reaches the condenser. In order to try out this idea a few tests were made at the Forest Products Laboratory at Madison, Wis., with a small Cottrell precipitator by treating the gases from the experimental retort, in which 50 to 60 lb. of wood is distilled per charge. The Cottrell precipitator was connected between this retort and the condenser.

Description of Apparatus

The precipitator, as shown in Fig. 1, consisted of a three-pipe unit contained in a shell made of 6-in. wrought-iron pipe and fittings. The collecting electrodes consisted of three pipes of light sheet steel, 2 in. in diameter and 24 in. long. The discharge electrodes, which hung through the central axis of the pipes, consisted of small chains, weighted at the bottom to keep them taut. The chains were later replaced by roughened $\frac{1}{8}$-in. rods. The discharge electrodes were hung from a plate above the tubes and were spaced in proper position by means of a spacer-frame below the tubes. The top plate was carried on a pipe which extended through the insulator at the top of the precipitator. As indicated in Fig. 1, this insulator served as the support for the discharge electrodes as well as an inlet bushing, and was the only electrical insulation used.

The path of the gases can be readily seen in Fig. 1. The raw gases from the retort entered the precipitator at a point just under the header plate, passed downward around the outside of the tubes, in order to insure equal distribution, and finally up through the tubes, where the tar was removed by the electrical action.[1] The cleaned gas passed from the precipitator to the condenser through a 2-in. pipe as shown.

Since the precipitator was fairly large in comparison with the size of the retort and since it, therefore, afforded a large surface for heat radiation and condensation, it was decided to prevent this condensation by lagging the precipitator and to hold the temperature at the desired point by means of external heat.

The electrical equipment used for providing the unidirectional high-voltage current for use in the precipitator is shown in Fig. 2, and consisted of a synchronous induction motor which drove a mechanical rectifier, a special high-voltage transformer and auxiliary apparatus such as switches, meters, rheostats, etc. The power supply was 110 volt, 60-cycle alternating current. This was stepped up to 220 volts by means of an autotransformer; the special high-voltage transformer raised the 220-volt current to the voltage desired (10,000 to 15,000 volts). This high-voltage current was then rectified to unidirectional current by means of the mechanical rectifier, which is practically a synchronously driven switch. The electrical connections between the various items of the equipment are shown in Fig. 3.

Defects in Experimental Apparatus

As is the case with any small-scale apparatus, there were a few inherent defects in the design of this experimental precipitator, all of which are readily eliminated in larger or commercial installations. The discharge electrodes first used in these experiments were chains hung from the top spacer-plate. As soon as the high-voltage power was applied to the precipitator, these chains showed a tendency to swing due to the electrical stresses set up and the electrical windage. These swinging chains, weighted at the bottom, acted as pendulums, and it was impossible to stop the swinging except by ceasing operations. As soon as the chains

[1]The theory of electrical precipitation has been discussed so frequently in various publications that it was not deemed necessary to repeat it in this article.

started to swing, the proper gap distance between them and the pipes was not maintained and serious disruptive arcing took place, thereby destroying the efficiency of precipitation. In order to eliminate this trouble, the chains were replaced with discharge electrodes made of ⅛-in. rods roughened to give points for electrical discharge. This eliminated the swinging, but it also meant the use of an electrode less satisfactory from the viewpoint of electrical discharge. In a commercial installation consisting of a greater number of pipes of larger size, it is a simple matter to install a rigid electrode system and still have the benefit of the superior discharge from chains.

Another difficulty encountered with this test precipitator was electrical insulation. As can be seen from the sketch of the precipitator, Fig. 1, the insulation was more or less in the path of the gas flow, with the result that any small amount of tar, oil or other material that passed through the pipes had a tendency to adhere to the rough surface of the fused silica and thus create a path for the leakage of electrical power. Several runs were characterized by insulation trouble, with a resultant loss of efficiency. In larger precipitators this is readily eliminated by installing all insulation in separate compartments entirely removed from the gas stream, thereby keeping the insulators clean at all times.

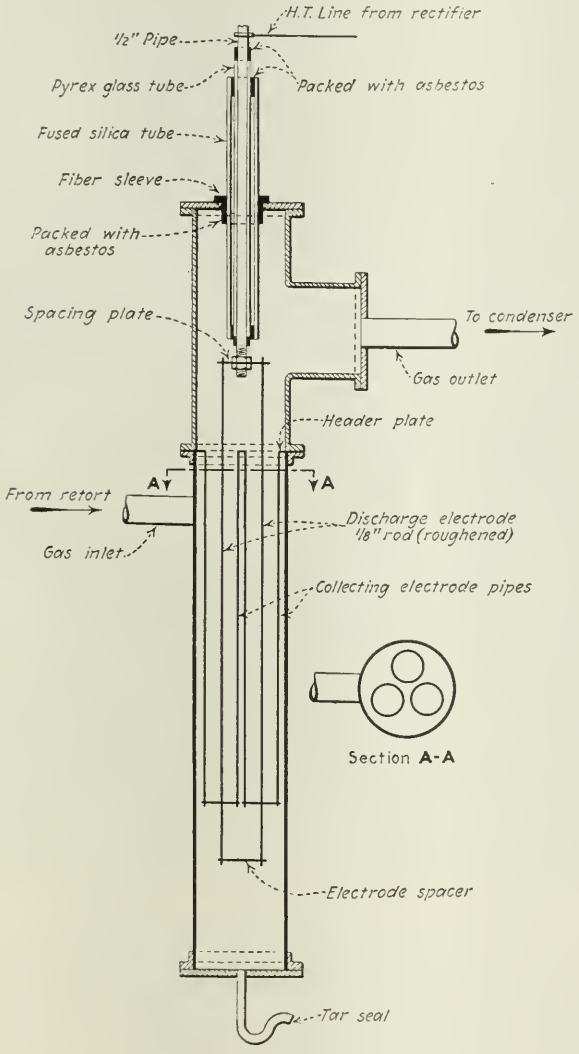

FIG. 1—TEST PRECIPITATOR FOR TAR

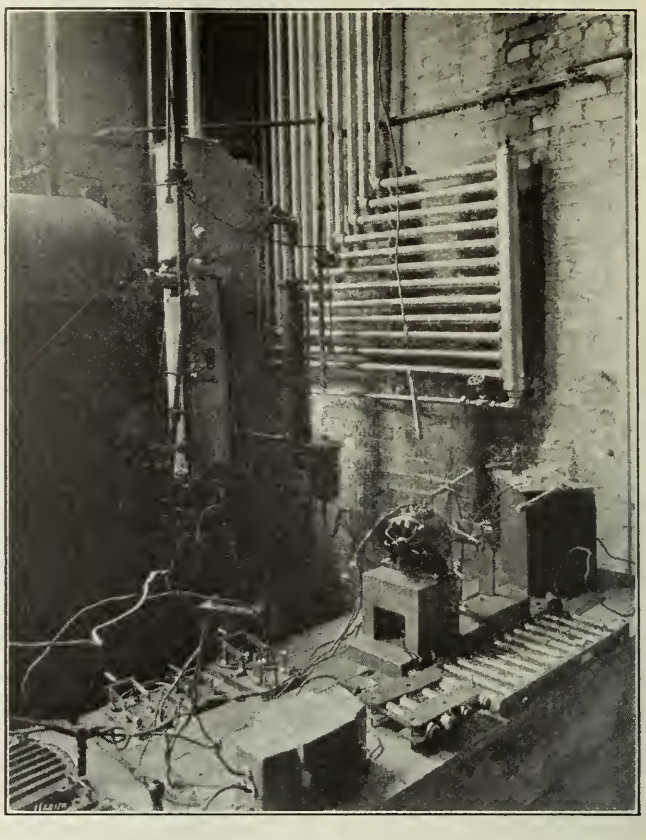

FIG. 2—COTTRELL PRECIPITATOR IN USE WITH WOOD-DISTILLATION RETORT

Tar Precipitated as Liquid Under Proper Temperature Conditions

During the first two runs the precipitator was heated to give the vapors at the outlet from the precipitator a temperature of about 160 deg. C. After the precipitator had been in operation under these conditions for a short time and before the runs were half completed serious arcing occurred in the precipitator, and the current had to be turned off during the rest of the distillation. On examining the inside of the precipitator it was found that a deposit of hard pitch had built up from the inside surface of the tubes toward the chains, and in one case this deposit reached all the way across between the tube and the chain, making a dead short-circuit. This material was very brittle and on being heated to high temperatures coked without any tendency to melt.

This indicated that the material being precipitated consisted of a pitch so very hard that at the temperature of the precipitation it did not flow readily and finally built up a solid deposit. This was probably due to the fact that at the temperature of the precipitation all the oils, even the higher boiling oils, were in the form of a pure vapor and, therefore, passed through the precipitator. Only the particles of hard pitch were in liquid form and this product was, therefore, the only material precipitated. In the next runs the temperature of the precipitator was kept near 100 deg. C. and at times a small amount of water may have been condensed in the precipitator. Under these conditions the deposit was a liquid tar containing pitch, oils, and perhaps a small amount of water corresponding to settled plus dissolved tar. This tar was not very thick even at ordinary temperature and at the temperature inside the precipitator it was sufficiently liquid so that it drained from the tubes without any difficulty and there was no

short-circuiting at any time throughout the run. This precipitated tar flowed from the trap in the bottom of the precipitator continuously throughout the latter part of the runs.

Condensate Low in Soluble Tar

The distillate which passed through the precipitator and was condensed and collected was clear and with only a little color during the first part of the run, but during the last part the color became darker and a small amount of dark-colored oil separated from the pyroligneous acid. This pyroligneous acid, however, was not so dark as that ordinarily obtained and on distillation it was found to contain only 3.3 per cent of soluble tar, whereas the ordinary pyroligneous acid obtained from the same retort contains from 12 to 15 per cent soluble tar.[2] An acetate of lime made by neutralizing this pyroligneous acid just as it came from the condenser contained 77.8 per cent calcium acetate whereas laboratory-made acetate of lime from redistilled pyroligneous acid contained 82.5 per cent calcium acetate.

Although a large proportion of the pitch had been stopped in the precipitator, yet a sufficient quantity came through to contaminate the acetate seriously. Another run was made in which it was attempted to keep the voltage higher, but this could not be done without serious arcing. It was finally decided to make another

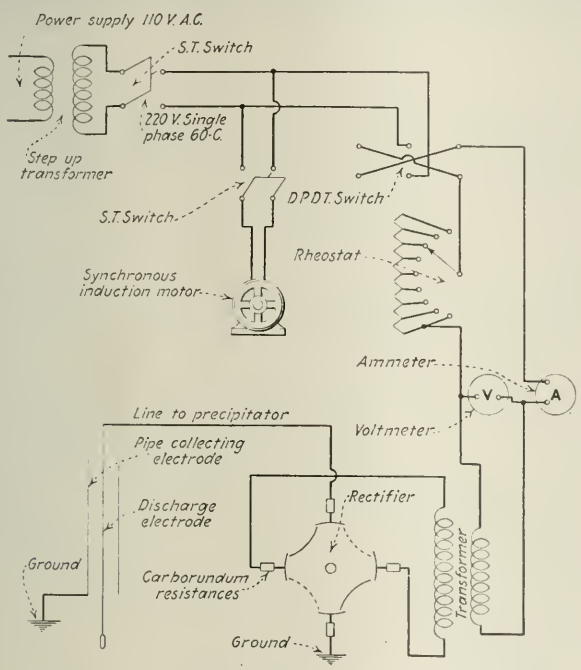

FIG. 3—TYPICAL PRECIPITATOR CIRCUIT

trial in which the distillation would be run at slower speed and this was done with a distillation taking 5½ hours instead of the usual time of 3½ hours. Even under these conditions, however, no better results were obtained.

Some Tar May Pass Through Precipitator as True Vapor

It is impossible to tell whether the soluble tar found in the pyroligneous acid which has come through the precipitator is due to a small proportion of tar fog which escaped precipitation or whether it is due to materials which came through the precipitator as a pure vapor but which polymerized to a non-volatile pitch either on neutralizing with lime or on distilling during the soluble tar determination. This assumption that the contaminating material came through the precipitator at least in part as true vapor is very plausible, since Klason[3] has shown that there is a continous decomposition of the primary tar from the distillation of wood into a secondary tar consisting of pitch and heavy oils. In the small retort used in these experiments the distance from any decomposing particle of wood to the precipitator is very short and the transformation of the primary tar into secondary tar may not have been complete before the precipitating chamber was reached. If this was the case, there might be a formation of non-volatile pitch in the vapors after they had passed through the precipitating chamber. Therefore, a non-volatile material would be found in the distillate through no fault of the precipitating apparatus.

Commercial Units Should Give Better Results

There is more opportunity in a commercial-sized retort for the decomposition of primary tar to secondary tar before the precipitator is reached, in which case the tar would be removed from the gas in passing through the precipitator. On the other hand, if this tar came through the precipitator as a fog, it was because the velocity of the gas passing through the pipes was too great to permit of complete precipitation. The use of a greater number of pipes would overcome this, as the efficiency of precipitation varies inversely as the velocity of the gas through the precipitator.

Conclusions

Although the small-scale experiments have not removed the last traces of pitch and although a satisfactory acetate of lime could not be made from the directly neutralized pyroligneous acid, yet the experiments have shown that the general idea of precipitating tar from hot vapor is a possibility. Furthermore, there is still no reason to believe that in commercial-scale apparatus the formation of secondary tar may not be more complete before the vapors leave the retort and that a purer pyroligneous acid might not, therefore, be obtained by this method.

Switzerland's Aluminum Industry

Before and even during the war, the production policy of the Swiss aluminum industry was directed toward supplying the German aluminum-working industries with raw aluminum. The depreciation of the mark and the increase in German aluminum production during the war, however, induced the German aluminum-working industries to abandon the Swiss metal. While in 1913 5,644,700 kg. of aluminum and in 1920 3,542,400 kg. were exported to Germany, these exports dropped in 1921 to 1,646,100 kg. This compelled the Swiss aluminum industry to look for new markets, which were found in 1921 in the United States and Japan. Thus in 1921, 3,420,600 kg. of aluminum, to the value of 8,523,000 francs, went to the United States, and 894,100 kg., valued at 2,075,000 francs, to Japan. Besides this, Switzerland's aluminum industry, concentrated in the Aluminium Industry Society of Neuhausen, is paying more attention to the aluminum-working industries of Switzerland.

[2] Although these figures might give the impression that the precipitator was only 15 — 3.3. ÷ 15 = 78 per cent efficient in removing tar from the vapors, it must be noted that not only 78 per cent of the soluble tar but all the settled tar was removed. This is an efficiency of about 90 per cent.

Evaporation of Potash Brines at Deep Springs Valley, California

Some Interesting Modifications in the Methods of Recovering Potash From Natural Brines Have Been Introduced at the Experimental Plant of the Inyo Chemical Co.— Checking Foaming in Evaporation—Removal of Borax in Centrifuge

By LEROY A. PALMER

EXPERIMENTAL and research work in the treatment of potash brines at a pilot plant in Deep Springs Valley, Inyo County, California, has developed what appears to be a very practical process for the economical extraction of the valuable portions of the great saline deposits found at different localities in the American desert.

The brine is obtained from a "salt marsh" or "dry lake," as the deposits are frequently called, of an area of about 1½ square miles. It is a typical saline deposit formed by the dessication of a Quarternary lake having no outlet, in which waters only moderately alkaline became, by continued addition of solid matter and evaporation of the water, a highly concentrated mass of alkaline minerals. The deposit is covered by a glistening snow white crust, the principal constituent of which is sodium chloride.

Nature of the Deposit

The strength of the solution increases toward the center of the deposit, which is marked by a "crystal body" in which supersaturation has occurred so that various sodium and potassium minerals have crystallized out in many interesting and unusual forms. The interstices of these crystals are filled with the brine from which they were thrown down, while below and on all sides of the crystal bed is a deposit of thin watery mud, in which the minerals exist, but, due to the presence of the mud, in less proportion than in the brine.

It is not the purpose of this paper to discuss the origin of this deposit. The reader who is interested in that phase may refer to Hoyt S. Gale's "Salines in the Owens, Searles and Panamint Basins, Southeastern California"[1] and in the portion referring to Searles Lake will find a description of conditions generally similar to those at Deep Springs Lake.

While this similarity of origin exists, the Deep Springs brines and muds have been found to be somewhat richer than those of Searles Lake. Gale reports[2] six analyses of anhydrous salts from Searles Lake by Walton Van Winkle of the Geological Survey which show an average of 6.28 per cent K and one by W. H. Ross of the Bureau of Soils which shows 6.06 per cent K, equal to 7.48 per cent and 7.28 per cent K_2O respectively. The hypothetical combinations in the anhydrous residue of the Searles Lake brine, based on an average of these seven analyses reported by Gale, are given in column A of Table I.

[1]U. S. Geological Survey Bull. 580. See also "Potash From Searles Lake," by Alfred D. Ropp, Jr., Chem. & Met. Eng., vol. 19, No. 6c, pp. 425-38, Sept. 26, 1918, and "Salts Refining at Owens and Searles Lake," by L. W. Chapman, Chem. & Met. Eng., vol. 24, No. 16, April 20, 1921.

[2]U. S. Geological Survey Bull. 580, pp. 276-277.

Columns B and C are analyses of two samples of brine taken from one of the test wells put down in the crystal body at Deep Springs Valley. Both samples are from the same hole, but C is lower than B due to the fact that surface water had got into the hole after B was taken and had diluted the brine. It is given for the purpose of certain comparisons to be made later. B_1 gives the hypothetical combination of the anhydrous residue of B. The potash content of these on a basis of percentage of the total solids is 25.6 per cent KCl in B and 21.5 per cent in C.

The muds, too, contain an appreciable amount of potash, but they also carry a large proportion of water-insoluble matter, principally silica, which amounts to more than 80 per cent of the total solids. Their potash content, due to this fact, is so much lower than that of the brine and there is so much of the latter available that we are justified in leaving the muds out of consideration as a future source of potash salts.

Separating the Salts

The process for separating the different salts contained in the brine is one of boiling out in which the temperature of the solution is varied and the salts are

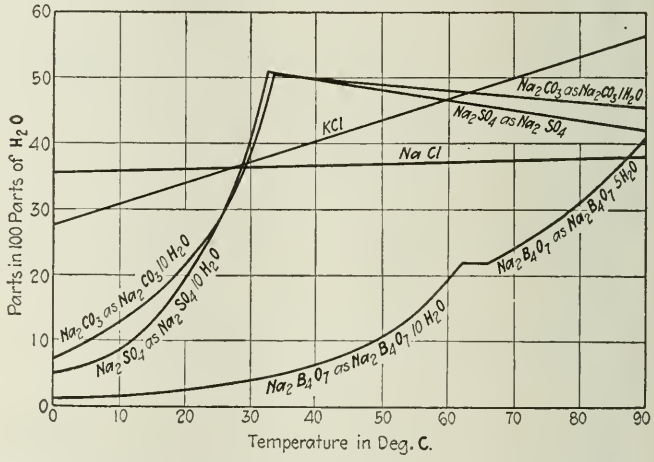

FIG. 1—SOLUBILITY CURVES FOR ALKALI SALTS FOUND IN POTASH BRINES

thrown down in the order of their solubilities. Fig. 1 shows the solubility curves of the commoner alkali salts reckoned in parts of the salt in one hundred parts of water and based on experiments with the individual salts. No curves showing the solubilities of the various salts in combination have been determined, as the solubility of each would vary with every change in the proportion of the salts to each other.

The principle involved in the process is simple and

has been applied, in one form or another, in many attempts to make a commercial product from natural brines of this character. But, as is frequently the case, efforts to develop the process on a practical basis have been beset by many obstacles, most of them unforeseen and of an unexpected nature.

The work at the Inyo Chemical Co.'s plant has been carried on by the Industrial Research Co. of San Francisco, under the direction of its president, Clinton E. Dolbear, and it is claimed that the process developed has overcome the usual obstacles and simplified the entire cycle of operations.

The experimental plant, shown in Fig. 2, has been built on the shore of the lake, into which a light pier

FIG. 2—EXPERIMENTAL PLANT ON SHORE OF DEEP SPRINGS LAKE

or runway has been built for a distance of about half a mile, so as to reach the crystal body. At the end of the pier is a gasoline engine and centrifugal pump, by which the brine is pumped to four concrete vats, each 20 x 20 x 1 ft. (3,000 gal.) on the shore adjacent to the plant.

In actual practice refrigeration will be used to chill the brine in these vats. Artificial chilling was not necessary in the experimental work, as this was carried on in the fall and winter when the nights were sufficiently cool at this altitude—about 5,000 ft.—to give the desired temperature by natural means.

The first step in the segregation process takes place in these cooling vats, in which the temperature is reduced to 10 deg. C., at which point the greater part of the sodium sulphate and some of the sodium carbonate crystallize out. The experiments show that an average of 31 per cent of the salts is removed at this stage and that the crystals take with them an equal proportion of the water of the brine as water of crystallization and as entrained moisture.

The effect of refrigeration is shown in column D of Table I, which is an analysis of sample C after it had been subjected to the chilling process described. The same on a moisture-free basis is given in column D_1.

The liquor remaining after the partial crystallization resulting from the chilling is drained to a sump in the mill and there mixed with the mother liquor from previous treatments in the approximate proportion of two parts of refrigerated brine to one mother liquor. A centrifugal pump raises the mixture from the sump through a 2-in. pipe line to a 1,000-gal. galvanized-iron tank on the second floor, preparatory to the second stage of the process.

A typical analysis of the mixture of refrigerated brine and mother liquor is shown in column E.

Evaporation

Evaporation is effected in a 30-in. single-effect Swenson "steam basket" type evaporator shown in elevation in Fig. 3. The evaporator is filled by gravity from the 1,000-gal. tank through the 2-in. liquor inlet shown at the left. In the first filling the liquor goes direct to the evaporator, but when this is filled and evaporation is under way the liquor is bypassed to a small tank in which is a float valve connected to a half-inch feed pipe. The flow to the evaporator is regulated by this valve so that a uniform water level is maintained about 3 in. above the top of the steam basket and a fixed volume of brine is kept in the evaporator. The float valve thus regulates the feed so that the inflow and evaporation balance.

The essential feature of this type of evaporator is the steam basket in the lower half of the cylindrical portion. This steam basket is cylindrical in shape, 20 in. in diameter, 30 in. in length, with thirty tubes, each 2 x 30 in., set in it longitudinally. Live steam is admitted through the 2½-in. steam line shown on the left, passes through the pipe in the upper part of the cylinder and into the top of the basket, the purpose of which is merely to expose a large heating surface to the brine which surrounds the basket and fills the tubes. One can get a good mental picture of the process by comparing it with the well-known water-tube boiler, the brine taking the place of the boiler water and the steam the place of the furnace gases. With the large radiating surface presented by the steam basket the brine is quickly brought to boiling, which, at this altitude, is from 211 to 217 deg. F., according to the density.

Checking Foaming

Here occurs one of the bugaboos of evaporation as applied to these natural brines. Due, supposedly, to the presence of organic matter, the liquor foams violently when the temperature is raised to boiling—

so violently, in fact, that the capacity of the evaporator is greatly reduced and a period of 38 hours was required in this case to concentrate the brine to saturation with KCl. Obviously a cycle of that length was expensive and some means was necessary to reduce the time required.

This foaming during evaporation is a trouble that has been encountered in all attempts to boil these natural brines, and a great deal of experimental work has been carried on at different plants in efforts to devise means to overcome it. Various processes, most of them only partly successful, have been tried. These have included the use of crude oil, gasoline, animal fats and oils, passing all brine through decolorizing charcoal, etc. Some of these were only partly successful, while others were successful in the matter of checking the foaming, but were too expensive to be of any value from a practical standpoint.

The introduction of slop distillate, not a new expedient, was tried at this plant by feeding it in slowly

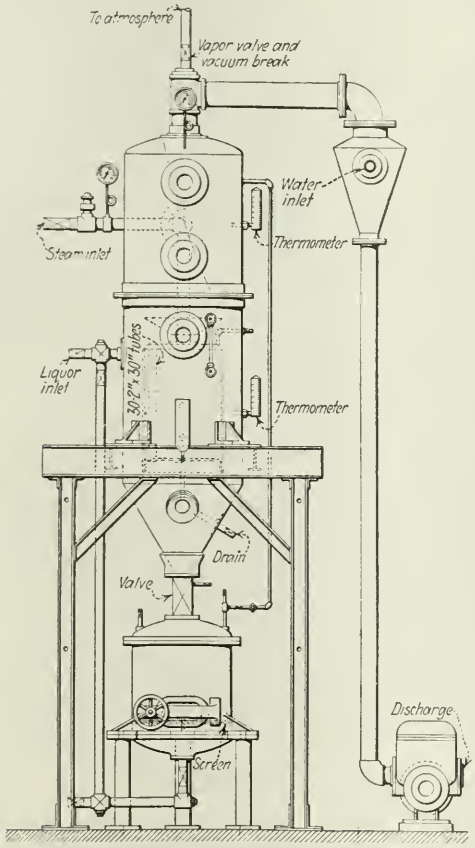

FIG. 3—ELEVATION OF SINGLE-EFFECT PATENTED BASKET TYPE EVAPORATOR

from a small reservoir. By increasing the surface tension of the liquor in the evaporator the introduction of the distillate retarded the foaming and cut the time required for saturation to 14 hours.

This was still much longer than was desired, and another method was tried. Thin strips of sheet lead were suspended in the brine with one end of each strip in contact with the steel of the evaporator. This set up a galvanic current between the lead and the steel which liberated oxy-chlorides from the brine and these exerted an oxidizing action on the organic compounds that were causing the trouble, the reaction serving to retard the foaming. The use of the lead strips cut the time required for saturation to 14 hours, the same as

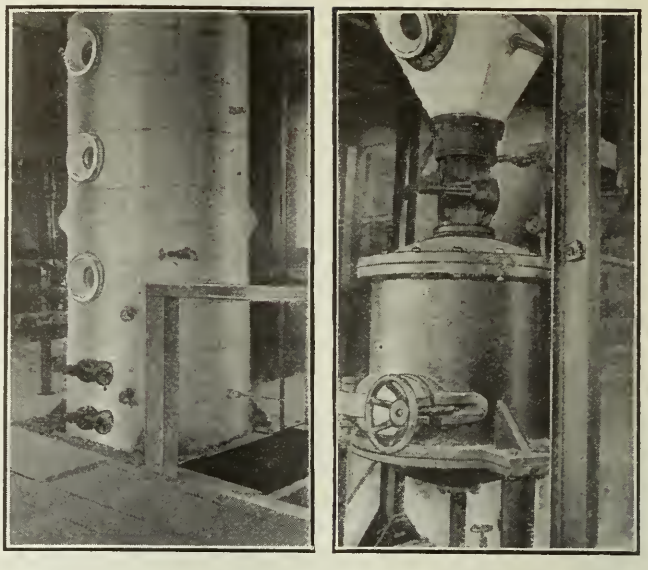

FIG. 4—VIEWS OF UPPER (AT LEFT) AND LOWER PORTIONS OF EVAPORATOR

with the slop distillate. The next step was a combination of the two and this met with success, complete salting out so far as possible at this stage taking place in 4 hours.

Salting Out

Reference to the solubility curves shows that above a temperature of approximately 65 deg. C. potassium chloride has a greater solubility than any of the other salts under consideration. With the increase in temperature in the evaporator sodium chloride is crystallized out, and almost immediately thereafter all of the remaining sulphate except about 3 per cent is thrown down, leaving a concentrated liquor in which KCl is the principal constituent.

During evaporation the brine is tested by drawing off about 50 c.c., permitting it to stand 30 seconds and then filtering it through a Gooch crucible. The dried salts from the filter paper are redissolved and tested with sodium cobalt nitrite, and if the reaction shows a satisfactory potash content, the evaporator is emptied.

The chloride, sulphate and carbonate crystals settle through the conical part of the evaporator into the lower cylindrical portion, from which they are removed through the door held by the hand-wheel and are then wasted. The enriched liquor is drained through the screen shown below the door with the hand-wheel and carried through the 2-in. pipe to the "crystallizer," which is merely two concrete tanks, each 2 ft. deep.

The refuse is emptied twice during a run. In column F is a typical analysis of the refuse at end of the first half of the run and G at the close, while column H gives the composition of the enriched liquor as collected in the crystallizing vat and H_1 the anhydrous residue of the same.

Separation of Potash

As the solution cools in the crystallizing vats, the potassium chloride and borax crystallize out together and are removed before the solution has cooled sufficiently to throw down the carbonates and sulphates remaining in the liquor. Column I gives a typical analysis of the mother liquor remaining at this stage, which is mixed with refrigerated brine and re-used.

The potash and borax crystals are heated in their

wet state by steam, which causes the borax to dissolve in the water entrained with the crystals and in its own water of crystallization. The potash and dissolved borax are then charged into a centrifuge the moving part of which is a vertical perforated cylinder 26 in. in diameter and 10 in. deep, lined with canvas filter cloth and turned at the rate of 1,350 r.p.m. As the centrifuge revolves, a jet of wet steam is turned into it to assist in driving the dissolved borax through the filter cloth so that the potash crystals are retained in the cylinder. The product that remains in the centrifuge contains about 2 per cent of water and small amounts of the various salts, other than potassium chloride, that make up the natural brine.

The last column (J) in Table I gives an average, on a moisture-free basis, of nine different lots of potassium chloride made by this process. The borax, although small in amount, is recovered in marketable quality. The entire cycle requires about 5 hours after the preliminary chilling.

Two patents have been applied for in connection with this process. One of these covers the process used to check foaming in the evaporator, and the other covers the use of the centrifuge for separating the potash and the borax. The latter has been issued, but the former is still pending.

The process as a whole, as described above, has been adopted by the Inyo Chemical Co. and construction has been started on a plant to have an initial output of 10 tons of potash per day.

I am indebted to Henry W. Carr, president of the Inyo Chemical Co., and to Clinton E. Dolbear, president of the Industrial Research Co., for assistance in collecting the above data and the arrangement thereof.

Legal Notes

By Wellington Gustin

Arkell Patents on Manufacture of Crinkled Paper Held Void for Lack of Invention

The United States Circuit Court of Appeals upheld the decision of the District Court holding the Arkell patents 790,021 and 790,022 void for anticipation and lack of invention, in view of the prior art, and holding his patent 790,023 void for lack of invention. These patents were granted in 1905 on applications granted in 1901, 1903 and 1904 respectively. The court finds that the plaintiff is using rights that belong to the public and are not subject to any monopolistic control under the patents named.

Broadly, the claims of the patents are on the process and on a machine for converting finished paper into stretchable crinkled paper for wrapping and packing purposes. The gist of this process is that the finished paper is first moistened or saturated in one or two baths, smoothed or "laterally stretched" by a convexed roller, pressed against and drawn around a smooth roller, from which it is detached by striking against a blunt blade, called a doctor blade, after which it is pulled off on a carrier so regulated in speed as to leave in the crinkled paper the desired percentage of stretch as the paper is dried.

The court found that crinkling moist paper by the general method of striking it against a doctor to be old. Such crinkled, stretchable paper was manufactured in substantial quantities by the use of the doctor as early as 1892. The Lysle patent 414,557, of 1889, shows knowledge of this process, as does the English patent 1927, of 1894 to Lewer and Edwards (272 Federal R. I.).

It is said that if moistening finished paper so that it will crinkle as paper still moist from the process of manufacture will crinkle involves invention, then Bainbridge's patent 584,108, issued in 1895, covered that point. The court says it makes no difference whether the moistening is done by submerging a roll around which paper is passing, or by running the paper from roll to roll through one or more saturating baths, or by spraying, or by a combination of any or all these processes. To dampen finished paper so that it will crinkle may be done in a great variety of ways, with only ordinary mechanical skill applied to devices in common use for decades.

The court says the "selection and putting together of the most desirable parts of different machines in the same or kindred art, making a new machine, but in which each part operates in the same way as it operated before and effects the same result, cannot be invention.

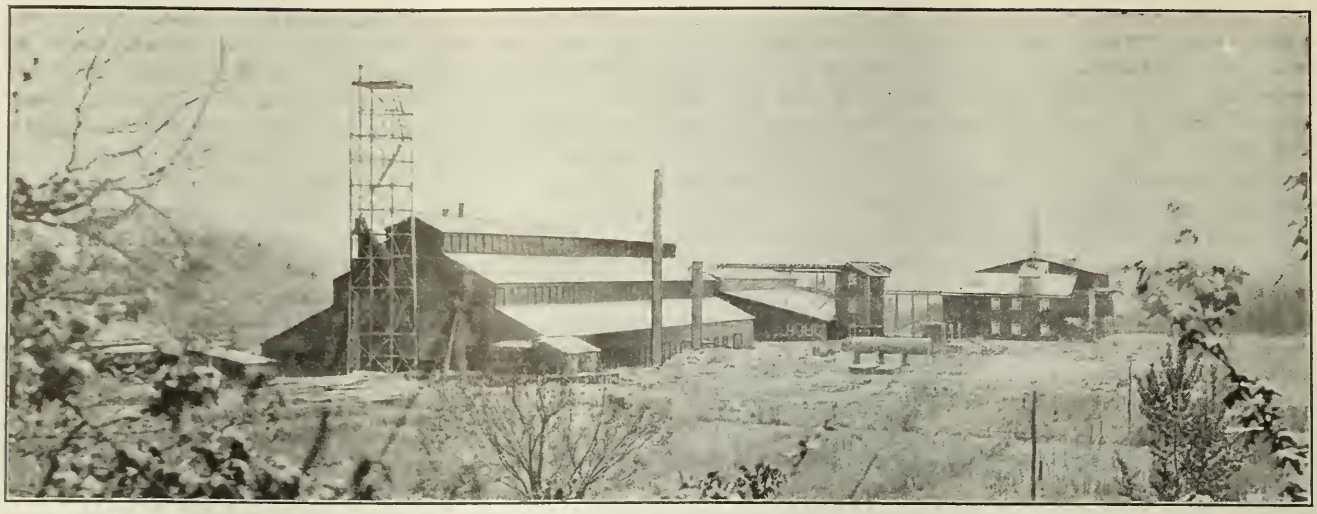
"To sustain a patent on a combination of old devices, it is well settled that a new result must be obtained which is due to the joint and co-operating action of all the old elements."

Precedent Opinion Cited

The advice of the United States Supreme Court in Atlantic Works vs. Brady (107 U. S., 192) should be valuable to those interested in patents. It was applied in this case. It says:

"The process of development in manufactures creates a constant demand for new appliances, which the skill of ordinary head workmen and engineers is generally adequate to devise, and which, indeed, are the natural and proper outgrowth of such development. Each step forward prepares the way for the next and each is usually taken by spontaneous trials and attempts in a hundred different places. To grant to a single party a monopoly of every slight advance made, except where the exercise of invention, somewhat above ordinary mechanical or engineering skill is distinctly shown, is unjust in principle and injurious in its consequences.

"The design of the patent laws is to reward those who make some substantial discovery or invention, which adds to our knowledge and makes a step in advance in the useful arts. Such inventions are worthy of all favor. It was never the object of those laws to grant a monopoly for every trifling device, every shadow of a shade of an idea, which would naturally and spontaneously occur to any skilled mechanic or operator in the ordinary progress of manufactures. Such an indiscriminate creation of exclusive privileges tends rather to obstruct than to stimulate invention. It creates a class of speculative schemers who make it their business to watch the advancing wave of improvement, and gather its foam in the form of patented monopolies which enable them to lay a heavy tax upon the industry of the country, without contributing anything to the real advancement of the arts. It embarrasses the honest pursuit of business with fears and apprehensions of concealed liens and unknown liabilities to lawsuits and vexatious accountings for profits made in good faith."



THE BELLE ALKALI CO. PLANT AT BELLE, W. VA.

Up-to-Date Methods in a Bleaching Powder Plant

The Bleaching Powder Plant of the Belle Alkali Co. at Belle, W. Va.—How a War-Born Plant Has Introduced Modern Methods That Help to Overcome the Disagreeable Side of a Standard Method of Manufacture—Industrial Trend Indicated by This Improvement

BY GRAHAM L. MONTGOMERY

UTILIZING the legacy of chemical plants left on our hands as an inheritance from the late war has not proved a uniformly easy task. It has either been necessary for the war-born plant to create a market for a new product in a time of depression or the plant has had to compete with the products of long-established plants in the manufacture and sale of a staple product. Under these conditions there are in general only two cases which have permitted the profitable exploitation of these properties. First, where there is a real demand for a product not formerly made in this country and not at the present time brought in from abroad at an unduly low price; and second, where, through some factor such as location, equipment or organization, the new plant can sell the same product on at least as favorable terms as the old, or can produce a better product to sell on the same terms.

THE BELLE ALKALI CO.

One of the plants where location and equipment have enabled a business to be built up in the face of old-established competition is to be found in the Belle Alkali Co., at Belle, W. Va. This plant was erected by the government during the war for the production of chlorine gas; but was never operated under government supervision, being completed only after the armistice had been signed. Some time thereafter the Belle Alkali Co. was organized, and purchased the plant from the government. The plant was extended and changed to make possible the manufacture of bleaching powder and caustic soda in addition to chlorine.

The object of locating a chlorine plant at Belle is the immediate proximity of a supply of salt. In fact, the plant stands over the wells, and the brine, which occurs at the 500-ft. level, is pumped up as needed. This gives a supply of the basic raw material of manufacture for chlorine in the desired form without any outlay for shipping. The other principal item needed for the chlorine manufacture is electrical power. Here again the Belle plant is unusually fortunate, as it has on the property sufficient flow of natural gas to supply all power needs at the present, and if in the future the gas wells should run out, there is also on the property a mine of high-grade bituminous coal. Being in the valley bottom of the Kanawha River, a plentiful supply of good water is assured at all times.

From the point of view of accessibility to market, Belle is also rather well situated. It is on the main line of the Kanawha & Michigan R.R., with ready access to the main line of the Chesapeake & Ohio R.R. at a mid-point between the markets of the Central and Eastern sections of the country and also within easy access of the Southern textile markets. In addition, a good labor supply is almost always assured, as the overflow of labor from the extensive West Virginia coal-mining fields should always be sufficient to take care of this need. Here, then, is a plant where all the factors governing sound location seem to be satisfied.

GENERAL MANUFACTURE AT BELLE

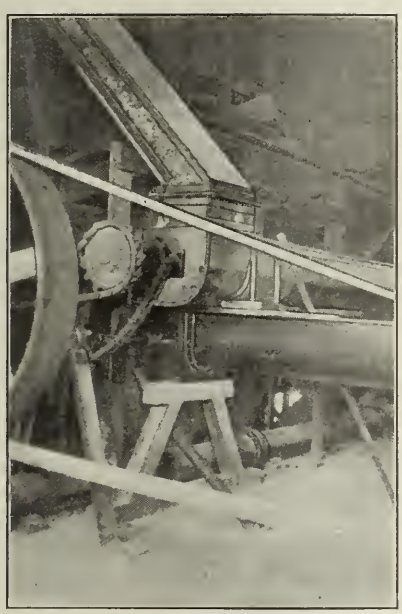
The primary manufacture of this plant was chlorine, by electrolytic methods. This is still the basis of manufacture, and chlorine and sodium hydroxide are the primary products. The market for the chlorine is not sufficient to absorb it all in the liquid or gaseous form and hence a part is now made into bleaching powder. The caustic is sold in the form of flaked

caustic soda, an up-to-date flaking plant having been added to the equipment left by the government.

The bleaching powder plant is the newest addition to the property. It is in building the plant wherein this manufacture occurs that modern and highly efficient mechanical equipment has been adopted. This equipment marks a step in overcoming the usual difficulties under which a bleaching powder plant labors and points the way for a perhaps more extensive use of mechanical methods which will some day eliminate these difficulties altogether. Also, it is largely due to these methods that this company has been able to turn out a good product on such advantageous terms as to assure its place in the market.

Manufacture of Bleaching Powder

The manufacture of bleaching powder has been a standardized process for many years. The only changes that have occurred in this manufacture are refinements in method and are not basic. Briefly, the process consists of bringing hydrated lime into contact with chlorine gas in a suitable chamber, the lime combining with the chlorine to form the bleaching powder. This is a simple process; but it is an intensely disagreeable one for the workers to handle if hand methods are in force for its operation. In the first place, the lime is generally received at the bleaching powder plant in an unslaked condition and must be



CENTRAL POINT OF LIME-CONVEYING SYSTEM, SHOWING ELEVATOR *D* AND CONVEYORS 5, 6, 7

hydrated. This slaking is attended by the evolution of heat and gas and there is much dust raised. As a consequence, hydrating machines in which the lime is thoroughly treated with just the correct amount of water have been designed and their use is now general.

After the lime has been hydrated and screened to the proper size it is introduced into the chlorinating chamber or chambers. In its simplest terms, the chlorinating chamber consists of a lead-lined or concrete chamber about 20 ft. in width and from 40 to 100 ft. long and from 6½ to 10 ft. in height. The hydrated lime must be spread over the floor of this chamber, generally to a depth of about 4 in. In order to make a more efficient contact between the lime and the gas, it is found necessary to scarify the surface of the lime into ridges, until the whole surface is made up of alternate hills and valleys, the sides at an angle of 45 deg. This is a hard job for the workers, for some chlorine is likely to be present in the chamber and the dust from the lime is also unpleasant in effect. In making bleaching powder from the weak concentrations of the gas which result from some of the methods of

CONVEYOR 6, ABOVE CHLORINATING CHAMBERS, ALSO SHOWING CHLORINE DISTRIBUTING SYSTEM

chlorine manufacture, machines have been introduced to do this work mechanically, but with the strong gas available from electrolytic methods these machines do not yet seem to be in the form where continuous and efficient service can be obtained from them. So, for the present at least, this operation remains a hand operation.

Difficulties in Packing Bleaching Powder

After the lime has been chlorinated, it remains to remove it from the chlorinating chamber and pack it in the container in which it is to be shipped as the bleaching powder of commerce. To remove the bleaching powder from the chamber it is either raked to one end and hence out or it is raked to chutes leading from the floor of the chamber, the chamber being raised and the containers being loaded underneath. It is scarcely possible to get all the chlorine gas out of the chamber and there are always fumes and deleterious dust given off from the powder, so that the work of emptying the chamber is extremely trying. The powder is then to be packed into containers and these containers to be sealed before shipment. In this last process, more or less dust always escapes from the chute and container and gets in a paste on the floor of the packing room. This paste is an active oxidizing agent, and causes rapid deterioration of everything with which it comes in contact that may be oxidized. Also, there is a certain amount of chlorine which escapes from the bleaching powder when it is freed to the air, and this adds to the difficulties in this part of the work.

In most plants in this country today the lime in both the slaked and unslaked state is handled by mechanical equipment from its receipt in the plant through the hydrating process, the screens and to the chlorinating chamber. Due to the activity of the material beyond this point in oxidizing the usual metals of which

handling equipment is made, no attempt is made to use any machinery beyond the entrance to the chamber. This is with the exception that several plants have installed an industrial railway under the chambers. In this case, the container is filled while on a car and is then pushed to the header and the scales and so to shipment or storage as desired. This method employs about as much labor as the full hand method, does not save a great deal of time and is subject to the same labor turnover, due to unpleasant working conditions, that causes the chief drawback of the older methods. Also, the relatively expensive industrial railway equipment is subjected to a rapid deterioration.

At Belle this later succession of operations—i.e., the filling of the container and all the subsequent handling—has been made as nearly automatic as possible. Thus one more of the disagreeable factors that cause a high labor turnover and hence a high labor expense in this manufacture is on the way to solution, and one more cause of industrial disability is at least partly removed.

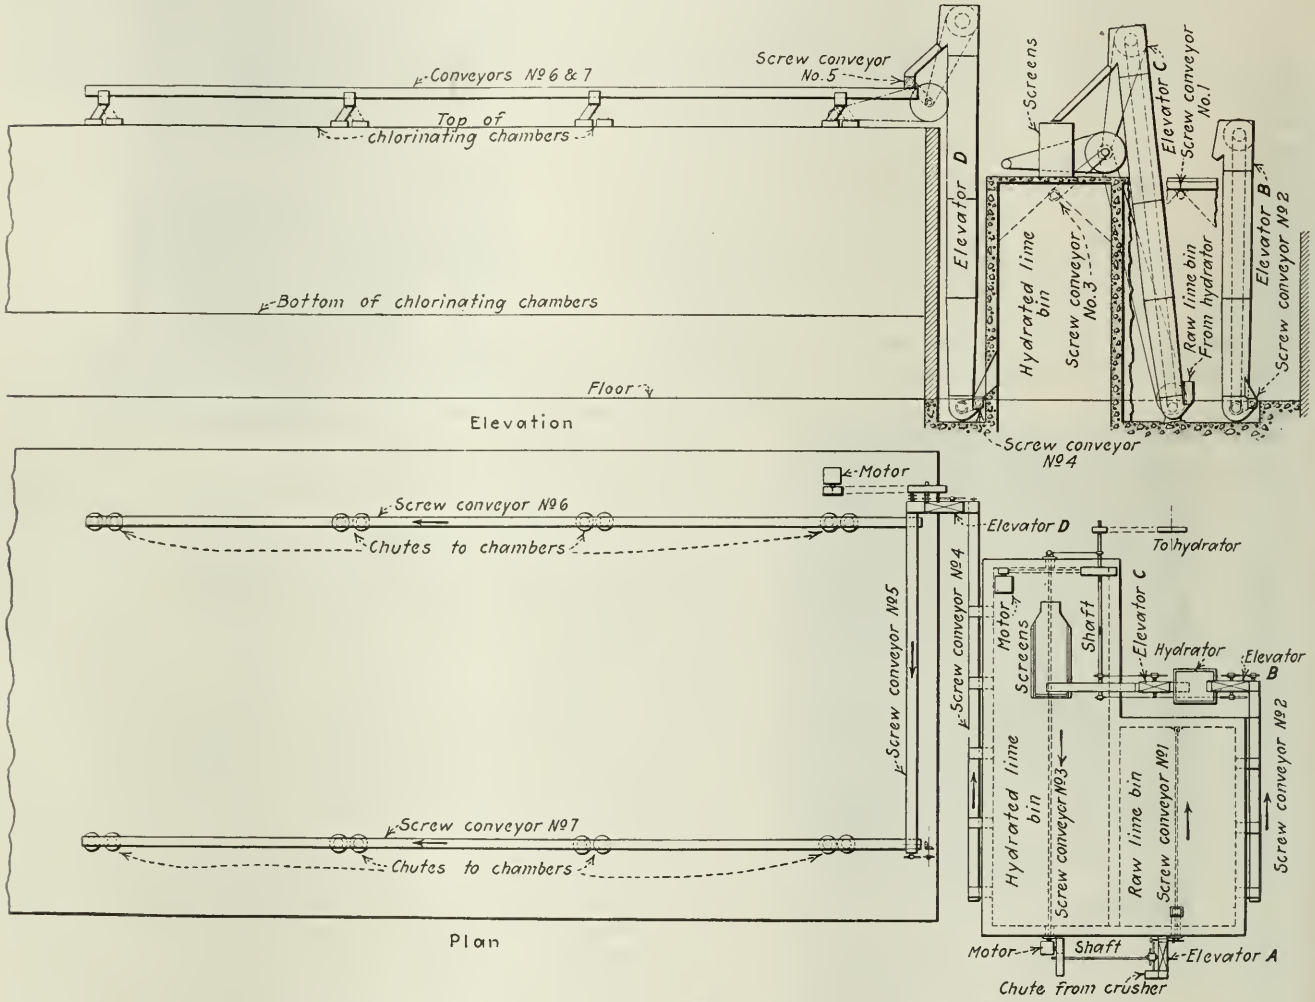


FIG. 1—CONVEYING SYSTEM FOR TAKING LIME TO THE CHLORINATING CHAMBERS

Making Bleaching Powder at Belle

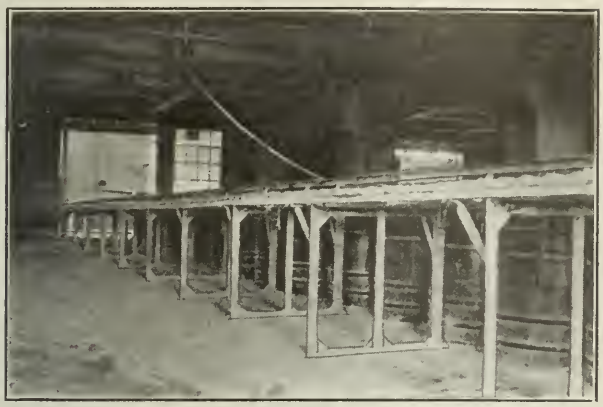
At Belle the unslaked lime is delivered in cars on the siding adjacent to the lime crusher shown in Fig. 1. This lime is unloaded by means of a portable belt conveyor directly to the hopper of the lime crusher. After passing through the crusher, the lime is delivered to the boot of the bucket elevator marked *A* on Fig. 1. This elevator, which has a dustproof casing, raises the lime a total distance of about 28 ft. and discharges it into the raw crushed lime storage bin. As the discharge into this bin is at one point only, it is necessary to have a means of distribution in order to utilize to full advantage the available storage space of the bin. This end is accomplished by the conveyor marked 1 on Fig. 1, which is a screw conveyor running open within the bin at the top and along the longitudinal center line.

From one side of the bottom of the raw crushed lime bin are three spouts which may be regulated to deliver an exactly determined amount of lime to the conveyor marked 2. This conveyor is a screw conveyor housed in a dustproof housing. The bottom of the bin is sloped to the side from which the discharge is taken so that the bin may be cleared without anyone going inside. Conveyor 2 delivers to the boot of bucket elevator *B*, also shown on Fig. 1, which is a standard bucket elevator housed in a special dustproof casing. Elevator *B* delivers the crushed lime to the hydrator. This is a mechanically driven hydrator wherein the lime is treated with the exact quantity of water necessary to slake it thoroughly and to leave it in the proper state for use in the chlorinating chambers except for the screening operation.

The lime, in being hydrated, passes down through the hydrator and is delivered from it into the boot of bucket elevator *C* at a point near the floor level as shown in Fig. 1. This elevator, like the others a standard elevator in a special dustproof casing, elevates the hydrated lime and introduces it into the screens. Here the material which is sufficiently fine is passed into the

hydrated lime storage bin by means of gravity chutes, while the small quantity which is too large is rejected to be reworked. A distributing conveyor, marked on Fig. 1 as conveyor 3, runs open in the top of this bin in the same manner as conveyor 1 runs in the raw crushed lime storage bin. The hydrated lime storage bin is a concrete bin similar to the raw crushed lime bin, with a sloped bottom to facilitate delivery of the lime. The gates of the spouts through which the lime is withdrawn are not in this case, however, of the regulating type, as there is no particular object in keeping strict account of the amount of lime taken from this bin.

The spouts in the bottom of the hydrated lime storage bin feed the screw conveyor marked 4 on Fig. 1. This conveyor delivers the lime to the boot of bucket elevator *D*, a standard elevator in a dustproof casing which raises the lime to a point about 40 ft. above the floor of the room, which is a sufficient height to deliver the lime by



GRAVITY CONVEYOR UNDER CHLORINATING CHAMBERS

gravity to the distribution system, which takes it to the different chlorinating chambers. This distribution system consists of a screw conveyor marked 5 on Fig. 1, which takes the lime from elevator *D* and delivers it to either screw conveyor 6 or screw conveyor 7. These two conveyors are located on top of the chlorinating chambers one about 10 ft. back of either face, and are sufficiently elevated to deliver the line through spouts by gravity into the chambers.

The chlorinating chambers are of concrete throughout and are 20 x 60 ft. by 10 ft. high. They are arranged in two tiers of four each, making a total of eight chambers, and have a clearance above the working floor under the lower chambers of about 10 ft. In each end of each chamber is a door of wireglass in a wooden frame which can be sealed gas tight and through which the process can be watched. These doors also permit the workers to enter when the lime is to be spread or the finished powder to be removed. The lime is introduced by means of two separate spouts for each chamber, one leading from conveyor 6 and one from conveyor 7. The chlorine is introduced through an appropriate system of tile piping under a slight suction, which is utilized at the close of the process for a means of exhausting any excess gas from the chamber. The finished powder is removed by means of four chutes leading from each chamber on the longitudinal center line and extending down to a point immediately above the highest point to which a container resting on the conveyor in the working space beneath would reach. It is still found necessary to do all the work of spreading the lime in the chamber preparatory to chlorinating and of raking up the finished powder and directing it down the chute to the container by hand. This is a disagreeable job and one attended by some danger, as the concentration of chlorine present, even with the utmost care, may sometimes exceed that which can be well withstood by the human system. The chambers are, however, exhausted until the continuous test on the exhaust gases does not show a trace of chlorine, and it is only chlorine that may be given up from the powder that causes the trouble. Besides this, all workers in the chambers wear an air helmet.

Handling the Finished Product

Directly under the chlorinating chambers is situated the conveying system used for loading, sealing and weighing the containers and delivering them to the shipping dock, and shown on Fig. 2. This is a new application of conveyors. Formerly, due to the oxidizing action of the bleaching powder, which it is impossible to keep off of any conveying system, it has not been thought feasible to introduce conveyors at this point. The system used here consists of a specially designed gravity roller system. In order to provide against corrosion as much as possible, this conveyor system has been made especially heavy in construction, a fact that was also made necessary by the heavy weight of the containers when filled with the powder, this weight going up to about 800 lb. It is expected that the frame, which is of heavy angle-iron construction, and the rollers, which are made of special heavy steel tubing, will withstand the effect of the bleaching powder for about 3 years. The particularly hard problem to be overcome was to get a free working bearing that would not be destroyed by the corrosive action.

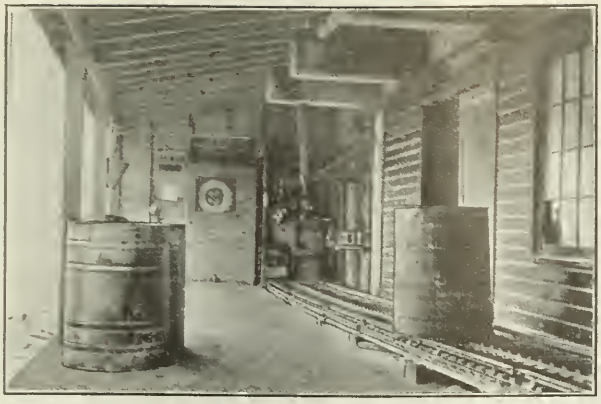
FIG. 2—CONVEYING SYSTEM FOR HANDLING FINISHED BLEACHING POWDER

This problem has been solved in the following manner: The end caps of the rollers have been made of heavy cast iron. In this casting a ball bearing is embodied, which is protected from the gas by having all joints threaded. Even with this precaution, there are openings into the bearing where the shaft goes through and where the means of lubrication is provided. In order to overcome this, an experiment has been tried which after nearly 6 months' use has been proved satisfactory. The bearings are all provided with Alemite lubricators, as shown in the accompanying illustration. This is a lubricator originally designed for use in automotive work, whe e it is necessary to introduce



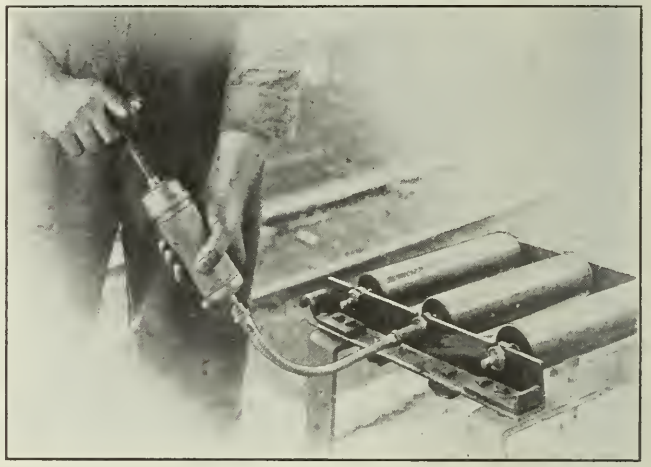
HEADING MACHINE, SCALE AND LOADING PLATFORM

the lubricant under pressure. In this case, the initial pressure under which the lubricant is introduced serves to keep any of the fumes from the powder from entering the bearing and the only precaution that has been found necessary is to keep the bearing well filled with this pressure lubricant.

The method in which this gravity conveying system is used is as follows: An empty container, which is in this case a large steel drum with one head removed, is placed on the gravity directly under one of the chutes leading from the chlorinating chamber above. A canvas extension is attached to this, leading down into the drum, which serves the purpose of preventing the bleaching powder from scattering while the drum is being filled. The gate in the chute is then opened and the drum is filled to the required height. The gate is then closed, and the canvas extension chute removed. Then, without any disturbance of the powder, the drum runs along the conveyor, which has such slight inclination that it is necessary to push the drum lightly to move it. The conveyor takes the drum around the curve shown on Fig. 2 and out onto the loading platform. Near the end of the gravity conveyor is the heading machine, where the drum, still without being moved in such a way as to cause any spillage of the powder, has the steel head sealed in place. It then runs onto a section of the conveyor which is situated on the platform of a dial scale and the weight of the filled container is taken, the tare having been noted before the drum was filled. It will be noted from Fig. 2 that there is one run of gravity conveyor under the center line of each tier of chlorinating chambers and that these all feed into a common line on the loading platform, which is served by a single heading machine and a single scale. The floor under the chambers and the loading platform are at car floor height so that the drum may be easily tipped onto a hand truck as it leaves the scale and wheeled into the car or stacked in some of the extra space under the chambers which serves as a storage reservoir for drums awaiting shipment. Special hinged sections are provided in the gravity conveyor along the loading platform so that these may be raised and the drums which are to be stored wheeled back into the building.

Advantages of This System and Its Significance

The most important advantage following the use of this conveying system for loading drums and handling them to shipment is that it is possible in this way to handle a greater volume in a given space and still maintain much cleaner working conditions than is the case with either the industrial railway or the hand methods. This is of real importance, as the conditions in this packing space are generally so disagreeable as to make the turnover among the employees overhigh, so high, in fact, that the cost of the work is unduly increased through breaking in new men and through delays incidental to having at times an inefficient crew. The gravity conveyors have been in service a sufficient time to prove their workability, and it is apparent that, even though the effect of the corrosion does cause them to wear out in a much shorter time than they would in other circumstances, the savings made through their use will more than make up for the replacement charges and the benefits derived from making the plant a healthier and safer place for men to work in will have a reflex action on plant conditions in general which will be felt throughout the plant. There is also to be considered that a gravity conveyor involves no operating charges for power and that it is the cheapest form of conveyor from the maintenance standpoint. All the parts are standard and it is very simple to replace a worn-out part without delaying the use of the conveyor for any appreciable time. This is one of the cases where it is better practice to employ a cheap and simple conveyor, even if it



SPECIAL ALEMITE LUBRICATION FOR GRAVITY CONVEYORS

does wear at what seems on first glance to be an unduly high rate, than it is to struggle along under the increased labor expense and burden of management which follow if the conveyor is not used.

It is worth while pointing out that such an installation as is described above indicates a tendency that is coming more to the fore in industry at the present time than it has ever before. That is the tendency to introduce refinements into present methods of manufacture which will make them more economical and safer to operate rather than to seek some entirely new way of doing things. It is to be hoped that such a tendency will not increase to a point where legitimate pioneering is discouraged; but it is a fact that in general the best profits are to be found in making a product for which there is already a good market in the most economical and best way. Very often this best way is to be sought rather in the refinement of an existing process than in the development of a new one.

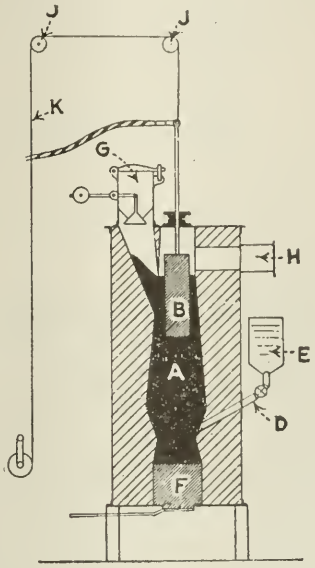
The writer desires to express his thanks to the management of the Belle Alkali Co., for permitting the above information to be gathered at its plant; and to thank the Alvey-Ferguson Co., which manufactured the conveyors described herein, for the layouts here reproduced.

Recent Chemical & Metallurgical Patents

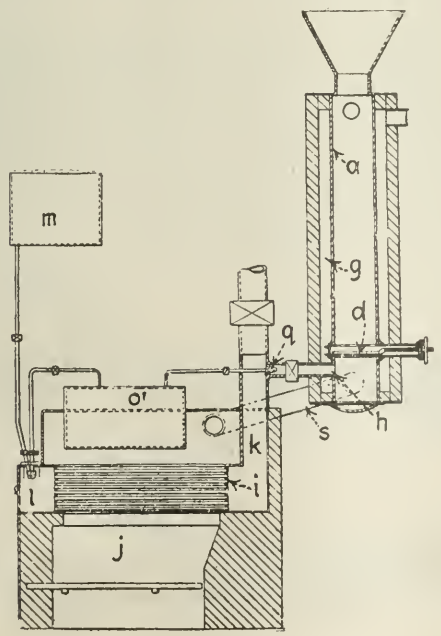
British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Building, Chancery Lane, London, England.

Carbon Bisulphide.—Apparatus for the production of carbon bisulphide comprises a shaft, *A*, provided with two electrodes, *B*, *F*, the latter being adjustable by means of the rope *K* and the rollers *J*. The adjustable electorde *B* rests freely on the layer of charcoal in the shaft, and is also surrounded by coal supplied through the hopper *G*. A moderate voltage between the two electrodes raises the temperature of the carbon column sufficiently to cause a brisk reaction between it and the sulphur, which enters through pipe *D* from heated vessel *E*. The sulphur enters near the constriction in the shaft which is the hottest region. Products pass away through the flue *H*. (Br. Pat. 174,040. Not yet accepted. Chemische Fabrik Griesheim-Elektron, Frankfurt-on-Main. March 8, 1922.)



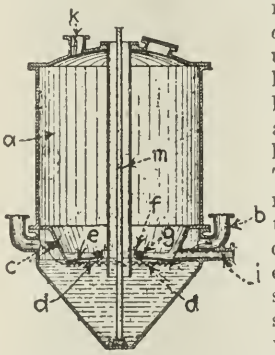
Gas Manufacture.—Coal or other carbonaceous material is treated in an externally heated retort with a gas containing 60 to 70 per cent of hydrogen or with a mixture of such gas and superheated steam at a temperature of from 500 to 600 deg. C., whereby an increased yield of condensable hydrocarbons, ammonium sulphate and coke is obtained. The coal is charged into a vertical retort *a* inclosed in a wall and having a perforated valve *d* for admission of the gases and for discharging the coke. Hydrocarbon oil, a byproduct of the process, from a tank *m* is sprayed with steam from a boiler *o*¹ into a vaporizing-chamber *l*, from which the mixture enters and is heated in iron pipes *i* communicating by a conduit *k* with the inlet *h* of the retort *a*. Superheated steam may also be supplied from a nozzle *q*. The hot gases from the furnace *j* serve to heat the pipes *i* and pass by a flue *s* to the space *g* around the retort. The distillation products leave the retort by an outlet and a rotary ram, having ribs on its under side and operated by a hand wheel serves to consolidate the fuel in the retort if required. To obtain a hard coke, during the last 20 to 30 minutes of coking the gas and steam, or steam alone, may be introduced at a temperature of from 700 to 900 deg. C. (Br. Pat. 174,165. J. Moeller, of Devon, and L. di Fonblanque, of Farnham, England. March 15, 1922.)



Carbonizing.—Carbonaceous materials such as lignite, brown coal and peat are powdered, mixed to form a paste with a hydrocarbon such as creosote, and ground to colloidal dimensions, the mass being then ground with coal tar or the like to form a liquid as described in specification 172,065. This colloidal liquid is passed under a pressure not exceeding 25 atmospheres through piping of small bore heated to not exceeding 500 deg. C. and is injected into a chamber in which vaporization takes place. The vapors are condensed and the permanent gases separated, leaving a liquid which may be used for fuel or may be further vaporized in the chamber, a semi-liquid mass remaining which is suitable as a binder for briquets, or, on still further vaporization, a residue from which briquets are formed is obtained. These briquets may be distilled to produce gas, coke, etc., or may be used in a gas producer. (Br. Pat. 175,670. G. P. Lewis, Westminster. April 20, 1922.)

Tanning.—After mineral or vegetable tanning, hides are soaked in an aqueous solution of pyridine to fix the tanning elements and permit subsequent washing and rapid drying without sweating or exudation to cause streaking or discoloration. The hides are usually soaked for 4 to 12 hours in a 10 to 25 per cent solution of pyridine. (Br. Pat. 175,362. T. B. Carmichael of Waterloo and W. H. Ockleston of Kelsall, England. April 12, 1922.)

Ammonium Sulphate.—A saturator, for use more particularly in the manufacture of ammonium sulphate, is constructed so that the passage of gas through the liquid is mainly horizontal. The saturator *a* is fitted with a bell *c* beneath the upper edge of which are the gas inlets *b*. The lower edge *d* of the bell is serrated, and extends for a short distance only below the level of the liquid in the saturator. The bell is fitted with a disk *e* by means of which the gas is made to traverse a radial path until it escapes through the aperture *f*. The edge of the bell is kept free from salt incrustations by means of a sprinkler tube *g*, the liquor from which flows through apertures and is kept at constant level by the overflow *i*. The gas finally leaves through the outlet *k*, and the salt is discharged through the siphon *m*. (Br. Pat. 175,649. Not yet accepted. H. Egeling, Weitmar, Germany. April 20, 1922.)



Depilation of Hides—Relates to the depilation of hides and skins in closed chambers by the action of heat and gaseous ammonia and consists in the use of ammonia in concentration of approximately 150 to 300 g. per cu.m. of chamber capacity and at temperatures of about 37 to 45 deg. C. The hides are previously soaked or wetted according to condition and are hung in a chamber, steam being admitted to raise the temperature and maintain a degree of humidity. Ammonia is admitted at the same time in the concentrations indicated and after 3 to 6 hours, when the roots of the hairs have been slackened, the ammonia is expelled from the chamber and that remaining in the hides is dissolved by rinsing either in the form of ammonia or after conversion into a suitable salt, such as ammonium carbonate, by admission of carbon dioxide or flue gases. The hairs are removed by hand or mechanically, the hides being kept warm by immersion in warm water or otherwise until the depilation has been effected. (Br. Pat. 175,314. O. Richter, Brandenburg. April 12, 1922.)

Synopsis of Recent Chemical & Metallurgical Literature

A High Pressure, Yielding-Plunger Pump for Vegetable Oil Expression.—Joseph Davidson of Atlanta, Ga.[1], speaking before the recent meeting of the American Society of Mechanical Engineers, described a new type of pressure pump that is being successfully used in connection with the extraction of vegetable oils by hydraulic pressure. The manner of applying the pressure has an important bearing on the efficiency of the expression process and also in the economy of the cloth used for covering the oil-bearing materials. The new pump is described as a high-pressure yielding-plunger pump and is claimed to represent a decided improvement in the hydraulic method.

A simple low-pressure pump is also used with plungers having a constant stroke, working in connection with a weighted accumulator and bypass valve, which maintains a pressure of approximately 600 lb. per sq. in. This supplies the pressure in large volume up to 600 lb. per sq.in. on all presses, and also supplies the pressure for operating the machine that forms the material into cakes, preparatory to being put into presses.

Referring to Fig. 1, the eccentric *A* imparts a reciprocating motion to the crosshead *B*. Yoke *C* is connected to crosshead *B* by means of two rods (one on either side, not shown in this figure) and moves fixedly with crosshead *B*. The two plungers *D* are fitted loosely, one in *B* and the other in *C*. Each plunger *D* has a collar *E* fitted against a shoulder. Between these collars *E* and the crosshead *B*, in one case, and the yoke *C* in the other, is placed a double-coil spring *F*, which receives the thrust of the plungers. The initial tension in the springs will stand a pressure of approximately 1,800 lb. per sq.in. against the plunger without yielding, but when the pressure in the pump barrels *G* reaches 1,800 lb. per sq.in., the springs will begin to yield, and continue to do so more and more as the pressure increases. Thus the stroke of the plungers is gradually reduced until the maximum pressure is reached, when they will cease to move; then the maximum pressure is held constant until the extraction of the oil is completed. The pressure is then released, and the cakes are discharged from the press, which is then refilled for another pressing operation.

Each chamber *I* around the discharge check has a ½-in. discharge connection, and the common practice in applying pressure to vegetable-oil presses is to run a separate and independent ½-in. pipe from each discharge connection to a press. Thus the high pressure on each press is supplied independently by one plunger, the pumps being constructed so as to provide one high-pressure yielding plunger for each press to be served. These ½-in. high-pressure pipes are connected directly to each press cylinder, no valve being required to cut off the pressure. Each press is equipped with an inlet valve for low pressure and a discharge valve; also a check to prevent the high pressure from leaving the press cylinder through the low-pressure inlet valve. When the discharge valve on the press is closed, the high pressure is confined and builds up the pressure to the maximum required. The springs supporting the plungers are then in action, taking up the movement of the crosshead. When the discharge valve is open while the cakes are being discharged and the press boxes refilled, the plungers are moving full stroke and the springs are not being compressed; the volume of liquid being moved by these plungers merely circulates under no pressure through the press cylinder, and out of the open discharge valve, back into the tank supplying the liquid to the suction of pump.

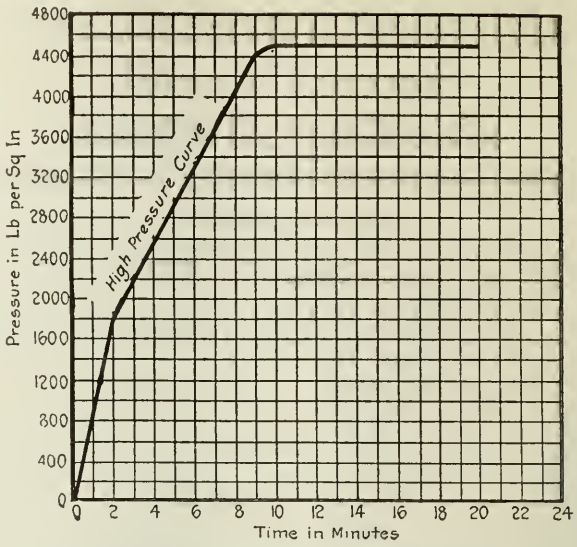


FIG. 2—PRESSURE CURVE WITH PLUNGERS WORKING AT 60 STROKES PER MINUTE

The use of this pump in supplying pressure to the presses used in the vegetable-oil industry obviates the necessity for any outside controlling devices such as safety valves, retarding, or choker valves, etc.

The power required is the minimum for the amount of work being done. The peak load comes when the pressure reaches 1,800 to 2,000 lb. per sq.in., and while the plungers are still moving full stroke. But from the moment the plungers begin to yield and the pressure continues to rise until it reaches the maximum and the plungers cease to move, the power required decreases; so that the maximum pressure is maintained with little more power than is actually necessary to overcome the friction of the moving parts of the machine.

Fig. 2 shows the pressure curve obtained by this pump when the plungers are making 60 strokes per minute.

This constantly and gradually increasing pressure, especially above 1,800 lb. per sq.in., obtains the maximum oil extraction due to the fact that the density of the material being pressed is increased very slowly. This gives time for the oil to be forced out of the material with the least possible resistance which would be set up in case the density was increased too suddenly by a rapid rise of pressure.

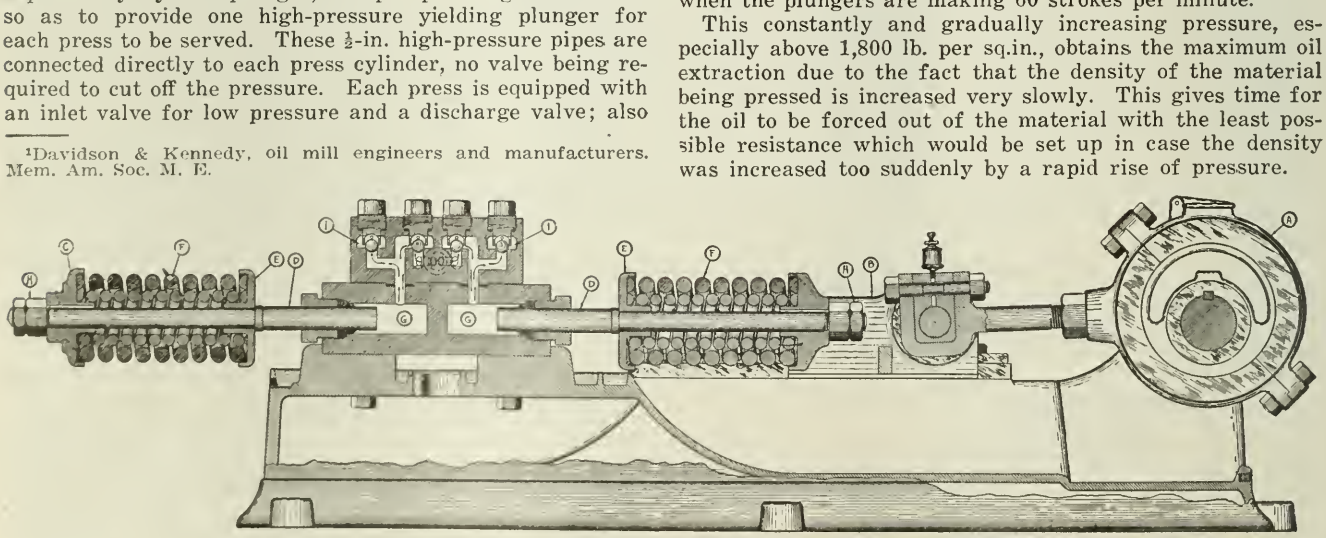

FIG. 1—LONGITUDINAL SECTION THROUGH HIGH-PRESSURE PUMP WITH YIELDING PLUNGERS

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Appropriations Announced for Chemical Projects of Department of Agriculture

The appropriation bill carrying funds for the Department of Agriculture for the year beginning July 1 is now a law, having been approved by the President. For the Bureau of Chemistry the bill appropriates a total of $1,277,631, of which $954,561 is for various investigations and $323,070 for administrative expenses.

Among the appropriations made are the following: Investigations relating to the application of chemistry to agriculture, $75,400; co-operation with other government departments desiring chemical investigations, $14,000; investigation and experiments in utilization for coloring, medicinal and technical purposes of raw materials grown or produced in the United States in co-operation with persons, associations or corporations, $56,260; investigations to determine methods for manufacture of table sirup and sugar and methods for manufacture of sweet sirups by utilization of new agricultural sources, $15,000; enforcement of food and drug act, including investigation of character of chemical and physical tests applied to American food products in foreign countries, $671,401; enforcement of act forbidding importation of impure tea, $38,000; investigation of naval stores, $10,000; investigation and development of methods of manufacture of insecticides and fungicides, $20,000; study and improvement of methods of dehydrating materials used in food, $20,500; investigations to prevent grain dust and other plant dust explosions, $25,000; investigation and development of methods of utilization of wool scouring, $9,000.

The Bureau of Soils is given $23,110 for chemical investigations of soils and $70,000 for fertilizer investigations.

The Bureau of Public Roads is given $175,000 for investigation of chemical and physical character of road materials and $15,000 for supervision of distribution of picric and other acids in clearing lands. For enforcement of the insecticide act $31,500 is provided for salaries and $156,510 for general expenses.

Sentiment Favors Embargo on Helium Exports as Military Precaution

Legislation proposing an embargo on helium exports, which soon is to be considered by a committee of the House of Representatives, differs from embargoes on commercial articles, it is pointed out, in that helium is primarily a weapon of warfare. Moreover, it is a weapon on which the United States has a monopoly. It seems to be the consensus among army and navy officials concerned with helium that it would be foolish to permit the exportation of this gas to a possible enemy.

The helium bill, it is further pointed out, does not put the government into business. There are numerous precedents in which the government develops fundamental facts and brings a process to the point where it can be developed commercially. In the case of helium, the cost of experimental work and the uncertainty as to its outcome would have precluded exploitation of helium resources by private capital indefinitely.

Syracuse Section, A.C.S., Elects

At a recent meeting of the Syracuse, N. Y., Section of the American Chemical Society held at Syracuse University the following officers were elected: A. C. Houghton, Solvay Process Co., president; Prof. Ross A. Baker, Syracuse University, vice-president; L. C. Jordy, Syracuse University, treasurer, and William Hicks, secretary.

Five-Year Course for Engineering Students Favored by Conference of Educators

Five year courses for students in engineering were favored by the deans and representatives of fourteen colleges at a conference held in Chicago, May 19. It was agreed that the first four years should be broadened to include more fundamental subjects and less highly specialized engineering and the last year should be devoted to intensive specializing in the chosen field. It is hoped that this concerted action will bring about the publication of the new courses of study in time to be effective not later than 1924. The resolutions embracing the conclusion of the conference follow:

> The undersigned engineering deans, directors and representatives, in conference assembled, hereby
>
> Resolve: That in order to meet the constantly enlarging responsibilities of the engineering profession we favor an advance in engineering education at this time that shall provide for five years of collegiate training for those engineering students whose aim is to be qualified to take positions among the creative leaders in the profession, and that such advance shall be made in substantial accordance with the following plan:
>
> 1. Remodel the present four-year engineering curriculums by substituting a substantial proportion of humanistic and fundamental subjects in place of an equivalent amount of advanced technical work. It is desirable that so far as possible the curriculums in the different branches of engineering shall be sufficiently uniform to permit students to defer their final choice of a specialty at least to the end of the second year.
>
> 2. Add a fifth year of advanced work, mostly or wholly technical and specialized to such an extent as desired.
>
> 3. The first four years of work shall lead to a bachelor's degree, and the fifth year to an advanced degree in engineering.
>
> Resolved: That each member of this conference will present the above recommendations to the authorities of his institution, and will report back at the second session of this conference, which is to meet at Urbana, Illinois, during the week of June 18, 1922, on call of the chairman.

Dean W. G. Raymond, State University of Iowa, Iowa City, Iowa, chairman; Dean O. N. Leland, University of Minnesota, Minneapolis, Minn., Secretary; Dean E. A. Hitchcock, Ohio State University, Columbus, Ohio; Dean A. A. Potter, Purdue University, Lafayette, Ind.; Dean M. E. Cooley, University of Michigan, Ann Harbor, Mich.; Dean G. W. Bissell, Michigan Agricultural College, Lansing, Mich.; Dean C. R. Richards, University of Illinois, Urbana, Ill.; Director J. F. Hayford, Northwestern University, Evanston, Ill.; Prof. Edward Bennett, University of Wisconsin, Madison, Wis.; Dean E. J. Babcock, University of North Dakota, Grand Forks, N. D.; Dean O. J. Ferguson, University of Nebraska, Lincoln, Neb.; Dean Anson Marston, Iowa State College, Ames, Iowa; Dean W. E. McCourt, Washington University, St. Louis, Mo.; Dean H. S. Evans, University of Colorado, Boulder, Col.

Aluminum Company Sues on Nitro Sale

The International Aluminum Co. has filed suit in federal court against the Charleston Industrial Corporation, the Virginian Power Co., A. B. Leach & Co., James Douglass, H. G. Scott, D. C. Schaeffer, C. S. Jenner and W. B. Payne, in connection with the transaction by which the federal government sold its $125,000,000 war-time explosive plants at Nitro for $3,000,000.

The International Aluminum Co. is asking damages of $50,000.

Better Progress on Tariff Bill—Dye Schedule Will Meet Opposition

Reports from Washington as to the chances of the passage of the tariff bill are more encouraging. Republican leaders believe that the filibuster is about spent and look for more rapid progress from this time forward, with the prospects favoring the passage of the bill late in July. Most of August would be required for the conference between the two houses. There are some who do not expect to see the bill become a law until after the November elections, but the consensus among Republican leaders is that the new tariff act will bear a September date.

May Abandon Dye Embargo

It is expected that Democratic opposition to the dye provisions of the tariff bill will get a great deal of Republican support. Senator George H. Moses of New Hampshire, Senator La Follette of Wisconsin and possibly Senator Lenroot of that state and Senator Norris of Nebraska may line up against the Republican program of protection for the dye industry. Senator Smoot of Utah is opposed to the embargo.

In the event that Senator Frelinghuysen of New Jersey, who is leading the proponents of the embargo plan, fails to "sell his idea" to the Senate it is probable that this type of protection will be dead for all time. High rates, however, will be provided and little or no opposition will be raised to protection by tariff rates.

Protests on Potash Rates

Senator Heflin of Alabama opposed the tariff on arsenic potash and fertilizer on the ground that it would be a burden to the farmers. Other protests on fertilizer rates are being registered by a committee of the National Fertilizer Association, which, on a platform of "free plant food," is in Washington favoring the free importation of potash, ammonium sulphate and nitrogenous waste of leather and tanning factories. The committee consists of Horace Bowker of New York, W. D. Huntington of Baltimore, F. H. Whipple of Hartford and J. Russell Porter of Atlanta, president of the Southern Fertilizer Association.

The Southern Fertilizer Association, through its president J. Russell Porter, has entered a protest against the potash tariff in a telegram to the House Ways and Means Committee.

"The Southern Fertilizer Association is strongly against a potash tariff," says the protest. "The burden of such a tariff will fall heaviest upon the Southern cotton farmer, and anyone at all familiar with the condition of the cotton farmer knows he is not able to bear it. Not only has the Southern farmer suffered heavily in consequence of the reverses of the deflation period, but on top of that has come the greatest disaster from the boll weevil ravages that the South has ever experienced.

"The cotton farmer is heavily in debt. His rehabilitation largely depends on fertilizers, and every cent added to the cost of fertilizers by the Fordney tariff bill will delay the time and increase the difficulties of his recovery.

"According to the provisions of the Fordney tariff bill, the cotton farmer must pay $25 more per ton on his sulphate or muriate of potash than he would pay if there were no tariff. It means just that much handicap to the cotton farmer in fighting his way back to prosperity.

"The tobacco farmer and truckers, though not in as deplorable a condition as the cotton farmer, would feel the tariff keenly, because these crops require large amounts of potash."

Paint and Pigment Schedules Passed

The Senate adopted the duty of 28 cents a pound on vermilion reds containing quicksilver, rejecting a motion of Senator Simmons of North Carolina to reduce it to 15 per cent ad valorem, by a vote of 18 to 31.

The duty of 30 per cent on paints, colors and pigments was adopted by the Senate, which on motion of Senator Smoot, for the Finance Committee, struck out the provision that any of these articles composed in chief value of coal-tar dyes or colors shall be classified under the coal-tar products schedule at 60 per cent ad valorem and 7 cents a pound.

On motion of Senator Smoot the Senate reduced the duty on strontium from 50 to 25 per cent ad valorem on the ground that the product is virtually controlled in this country by one concern.

The Senate then voted on various lead pigment duties, defeating by 21 to 47 an amendment of Senator King reducing the litharge duty from 2½ to 1½ cents a pound, and then adopting the 2½-cent duty.

Senator Jones of New Mexico argued that there was no justification for a duty on lead pigments, except the compensatory duty for the lead ore duty. An amendment by him to reduce the red lead duty from 2¾ to 1½ cents a pound was defeated, and the 2¾-cent duty adopted. An amendment by Senator Jones reducing the white lead duty from 2½ to 1½ cents a pound was also defeated 19 to 47.

On motion of Chairman McCumber, the Senate reduced the duties on chrome colors in paragraph 67 from 30 to 25 per cent ad valorem, defeating an amendment by Senator King to reduce them to 20 per cent, by a vote of 20 to 46. The duty on iron oxide and iron hydroxide pigments was reduced from 25 to 20 per cent ad valorem. By a vote of 21 to 42 a motion by Senator Underwood of Alabama to reduce the duty to 10 per cent was rejected.

Following extended debate in which the rates were attacked by Senator Jones of New Mexico, the Senate adopted the zinc oxide rates. The rates adopted are 1¾ cents per pound on zinc oxide and leaded zinc ores containing not more than 25 per cent of lead; ground or mixed with oil 2¼ cents per pound; lithopone 1¾ cents a pound.

On motion of Senator Smoot, the duty on thorium nitrate and oxide was reduced from 45 to 40 per cent. The duty on tin compounds was fixed at 25 per cent ad valorem, the Senate rejecting by a vote of 14 to 39 a motion of Senator Jones of New Mexico to reduce it to 10 per cent. The antimony salts duties as recommended by the committee were also adopted.

Army Engineers Urge Hydro-Electric Development of Tennessee River

The mineral resources and power possibilities of the Tennessee River and its tributaries in North Carolina, Tennessee, Alabama and Kentucky are the subject of exhaustive reports of army engineers transmitted to Congress. Reference is made to possible power developments on the river from Chattanooga to Riverton; and at Coulter Shoals, 40 miles below Knoxville. Recommendation is made that a more detailed survey be authorized looking to development of the rivers for navigation and power purposes.

The reports show that a large amount of hydro-electric power is now wasted annually in the upper section of the Tennessee River. It is stated that at Coulter Shoals a minimum 24-hour capacity of 14,000 hp. can be developed. Its transmission would be principally to Knoxville, where there is said to be a demand for power in excess of the supply. It is stated that for 90 per cent of the time in an average year 18,400 hp. would be available, while for 57 per cent of the time from 40,000 to 44,000 hp. may be developed. The initial cost of the project at Coulter Shoals is estimated at $6,346,500 and $257,300 annually for operation if built by the government. If built by private enterprise, the initial cost would be increased by $400,000.

Association of Chemical Equipment Manufacturers Announces Committee on Exposition Plans

A committee has been appointed by Dr. C. H. Kimberly, acting chairman, to work out plans for the future exposition exhibits of the Association of Chemical Process Equipment Manufacturers. The association was organized at a meeting in New York on May 11.[1]

The personnel of the committee is as follows: W. W. Smith of the Duriron Co., chairman; A. H. Stevens, of the Bethlehem Foundry & Machine Co.; H. T. Matthew, of the Quigley Furnace Specialty Co.; R. C. Campbell, of the United Filters Co. and C. L. Bryden, of the Vallez Filters Co.

[1]See Chem. & Met., vol. 26, No. 20, May 17, 1922.

Tariff Commission Issues Preliminary Summary of Census of Dyes and Coal-Tar Chemicals

A preliminary summary of Census of Dyes and Coal-Tar Chemicals, 1921, has been issued by the Tariff Commission on the request of Senator McCumber, chairman of the Finance Committee. This summary represents a special investigation made by the Tariff Commission as to the production and sales of dyes and other coal-tar chemicals in the United States. The final report will appear later under the title "Census of Dyes and Organic Chemicals, 1921."

The preliminary survey is based upon the production of 200 firms. It contains a brief summary of important developments in the output of dyes and coal-tar chemicals during 1921. Detailed tables are given showing the production of crudes, dyes and intermediates, and other coal-tar chemicals in 1921. In addition these tables contain, for the first time, the quantity and value of the sales of each product. Figures for each product are given in all cases where publication does not reveal the operations of individual manufacturers. Prices of a selected list of dyes from 1917 to 1921 are tabulated, with the invoice values of the same dyes imported in 1914. Comparison tables showing the quantity of production in 1920 and 1921 are given; also a comparison of the production of dyes classified according to method of application.

A detailed census of dyes imported for consumption in the United States during the calendar year 1921 is contained in the report. This tabulation shows the quantity and value of imports of individual dyes and the percentage of the quantity of each dye by countries or origin. A list of manufacturers whose production during 1921 was reported to the Tariff Commission is also included.

Affiliated Technical Societies of Detroit Hear Tour on Atmospheric Nitrogen

At a meeting of the Affiliated Technical Societies of Detroit, Mich., in that city on May 19, R. S. Tour, professor of chemical engineering at the University of Cincinnati, spoke on the fixation of atmospheric nitrogen.

The importance and necessity of nitrogen production was first mentioned in its relation to nitrogen fixation and the three commercial processes were described in a general way and their relative advantages and disadvantages stated. With the aid of lantern slides, the applications of the cyanamide and Haber processes at the United States nitrate plants were pointed out. The conditions under which these plants were built and their relation to the power project at Muscle Shoals were also considered. Finally, the proposals now before Congress for the private operation of the Muscle Shoals project were mentioned and their important points described. The address was followed by two reels of films showing Nitrate Plant No. 2 in construction and operation.

Badische Reports Increased Earnings

According to the *Boersen Courier* the Badische Anilin- und Soda-Fabrik realized in 1921 gross earnings of 404,733,311 marks, against 194,185,659 for the previous year. The net profit stands at 165,261,933 marks, as compared with 65,184,493 for 1920, and the dividend on the ordinary shares is 30 per cent, against 20 per cent last year, but owing to the increase of capital the amount distributed this year to ordinary shareholders is 120,000,000, compared with 36,000,000 last year. The report states that the Oppau ammonia works resumed operations in December and has been working at full capacity since February.

Charge Illegal Dye Sales Methods

The Federal Trade Commission has issued formal complaint against Dudley G. Gessler, engaged in selling dye and dyestuffs, in Philadelphia, Pa. The respondent has thirty days in which to answer, after which the case will be tried on its merits.

Respondent is charged with giving cash commissions or gratuities in substantial amounts to textile mill operators and supervising officials of customers to secure purchase for respondent's commodities over and to the exclusion of respondent's competitors' commodities.

Synthetic Chemical Industry Championed in House as Giant of Utility

A plea for support instead of criticism of the synthetic chemical industry was made by Representative Layton of Delaware in a speech before the House in which he characterized the synthetic chemical and the electrical industries as twin giants of modern power and usefulness.

Mr. Layton stated that while electricity enjoys the approbation of the public, the synthetic chemical industry is surrounded by ignorant prejudice which retards its progress and may if continued extinguish its development. He charged that the cry against those engaged in the national development of the synthetic chemical industry came from demagogue, German interests and the selfishness of the textile industry. The Congressman recalled the former public aversion to the steel, oil and copper interests, but said they were now looked on with pride as being part of our national strength and greatness.

"But when now the question of dyes comes up, involving the potentiality of our wage," he continued, "a howl of protest is raised against those engaged in manufacturing this and other products of coal tar as if some enormity were being perpetrated or perfected against the welfare of the people, notwithstanding the fact that synthetic chemistry and its results are paramount to any other scientific pursuit with characteristics of a fundamental necessity in peace and war. This is an age of chemistry. The dreams of the ancient alchemists have come true. The chemical laboratory possesses a greater productive power for health, agriculture, national defense, for use in textiles, for bodily ailments and for a multitude of other things than we find in all the electrical, steel or other establishments of the land."

Mr. Layton emphasized the great importance of fostering protection and establishment upon sure and impregnable basis of the industry founded upon science. It would be stupidly criminal for Congress to be influenced by forces that seek to destroy the industry, he asserted. He referred to Senator King of Utah as the chief champion of the interests of the German dye manufacturer in opposing the dye industry, and closed by advocating protection for the American industry.

Sodium Nitrate Awards

Seventy-nine bids were received by the Director of Sales for the 16,450 short tons of sodium nitrate sold on May 17. The average price received was $38.44. The successful bidders were as follows:

Trojan Powder Co.	Allentown, Pa.	200 tons	$42 20
Hubbard Fertilizer Works	Baltimore, Md.	100 tons	42 00
Senior Powder Co.	Cincinnati, Ohio	100 tons	41 40
Trojan Powder Co.	Allentown, Pa.	200 tons	41 20
Senior Powder Co.	Cincinnati, Ohio	100 tons	41 20
G. F. Taylor, Inc.	New York City	200 tons	41 00
Senior Powder Co.	Cincinnati, Ohio	100 tons	40 70
King Powder Co.	Cincinnati, Ohio	500 tons	40 50
Senior Powder Co.	Cincinnati, Ohio	100 tons	40 30
E. I. du Pont de Nemours	Wilmington, Del.	2,000 tons	40 30
Trojan Powder Co.	Allentown, Pa.	200 tons	40 20
Grasselli Chemical Co.	Cleveland, Ohio	1,000 tons	40.00
International Agricultural Corp.	New York City	165 tons	40.00
Granton Chemical Co.	New York City	375 tons	40.00
G. F. Taylor, Inc.	New York City	200 tons	40 00
Farmers Fertilizer Works	Elizabethtown, Pa.	100 tons	40.00
York Chemical Works	York, Pa.	100 tons	40.00
Trojan Powder Co.	Allentown, Pa.	200 tons	39 20
Union Explosives Co.	Clarksburg, W. Va.	250 tons	39.00
G. F. Taylor, Inc.	New York City	200 tons	39.00
Calco Chemical Co.	Bound Brook, N. J.	400 tons	38.50
Trojan Powder Co.	Allentown, Pa.	200 tons	38.20
Merrimac Chemical Co.	Boston, Mass.	150 tons	38.20
Wessel-Duval & Co.	New York City	4,000 tons	38.10
G. F. Taylor, Inc.	New York City	200 tons	38.00
Hubbard Fertilizer Works	Baltimore, Md.	100 tons	38 00
York Chemical Works	York, Pa.	100 tons	38.00
Atlas Powder Co.	Wilmington, Del.	5,000 tons	38.00

Power Company Supplements Shoals Offer

An offer to the War Department to purchase the Gorgas power plant and the government's interest in the railroad and transmission line from Gorgas to Muscle Shoals for $2,500,000 has been made by the Alabama Power Co. The offer has been submitted to the Senate Agriculture Committee by the War Department, this committee having under consideration the various lease offers.

Committee on Agriculture Investigates Charges of Fertilizer Monopoly

Charges which have been made in both houses of Congress of an alleged fertilizer trust are being investigated by the Senate Committee on Agriculture in connection with its consideration of the lease offers for Muscle Shoals. Secretary of Agriculture Wallace will be among those heard by the committee in an effort to get at the truth.

The charges that a "fertilizer trust" controls prices, fixing them so high that the farmers are unable to buy in quantities sufficient to meet their needs, were declared to be largely without substance by Francis L. Hawes, of the Federal Trade Commission.

Mr. Hawes told of the investigation of the fertilizer industry concluded in 1915 by the Federal Trade Commission, and declared that so far as the commission had learned since that time there was "no combination in restraint of trade" in the fertilizer business. Supply and demand, he said, were the factors regulating the industry at the present time. The committee, however, decided to look into the charges further.

Dedication of State Ceramics Building Arranged by Ceramic and Clay Workers' Societies

The New Jersey Clay Workers' Association and Eastern Section of the American Ceramic Society is perfecting arrangements for the dedication of the new state ceramics building at Rutgers College, State University of New Jersey, New Brunswick, on June 13, to be carried out during the regular annual commencement period at the institution. The building is now nearing completion, and represents an aggregate investment of close to $125,000, including donations made by companies in the industry in the state and vicinity. Brief addresses will be made by a few prominent speakers, including R. H. Minton, president of the Clay Workers' Association.

On the day following, June 14, the association will hold its regular mid-year meeting at the Country Club at Trenton, N. J. The business session will be limited to the afternoon, the morning being given over to sports and sightseeing, with possible visits to local potteries.

Petroleum Testing Methods Published

The long-promised report on "Methods for Testing Petroleum Products" as adopted by the Government Interdepartmental Petroleum Specifications Committee, is now available as Technical Paper 298 of the Bureau of Mines. These methods are formulated in what is virtually a handbook for inspecting laboratories. The use of the methods is compulsory under government purchases. The specifications required for such government purchases are included in another technical paper of the bureau also issued recently. It is Technical Paper 305 of the Bureau of Mines.

It is being urged that the standard testing procedures and the standard specifications thus recommended by the government be widely adopted in the interest of uniformity of petroleum marketing and tests. Copies of each paper can be obtained on application to the Bureau of Mines.

Chemical and Oil Company Organizations

During the month of April twenty companies were organized with a capital of $50,000 or larger to manufacture chemicals, chemical byproducts, drugs, etc., with aggregate capitalization of $20,055,000. This compares with a total of twenty-five such concerns formed in March, with combined indicated capital of $12,625,000. In the corresponding month of April of a year ago the aggregate capitalization of new companies formed was $9,390,000.

In this same month, April, 1922, ninety-five oil companies were organized, with an indicated gross capitalization of $154,590,000, as compared with an aggregate of seventy-nine oil companies, with capital of $50,000 or larger, formed in the preceding month, with combined capital of $156,571,000. In the same month of April a year ago 110 such companies were chartered, with a gross indicated capital of $227,470,000.

Personal

William Hutton Blauvelt has resigned his position with the Semet-Solvay Co., of Syracuse, N. Y., and has opened an office as consulting engineer in the Equitable Building, 120 Broadway, New York City, where he will give special attention to the carbonization of fuels and allied subjects. Mr. Blauvelt has been connected for many years with the Semet-Solvay and Solvay Process companies, and has taken a prominent part in the development of the byproduct coke industry in America. On account of his broad experience in the carbonization of coal, production of gas for domestic and industrial purposes, the recovery of byproducts and the general utilization of fuels, he is a recognized authority on these subjects. The first important installation of byproduct recovery gas producers, of the Mond type, was brought to this country and put into operation under his direction during the earlier years of his association with the Solvay companies.

F. F. Chapman of E. I. du Pont de Nemours & Co. is on a prolonged tour of the Western acid plants of the company.

Bjarne Colbjornsen, chemical engineer of the Stockholm Superphosphate Works, is in this country, making a survey of American fertilizer manufacturing practice.

Prof. A. C. H. Fasig, head of the department of applied sciences of Muhlenberg (Pa.) College, addressed the Kiwanis Club, Allentown, Pa., at its regular weekly dinner meeting at the Hotel Allen, May 18, on the subject "The Growth of Chemistry in the United States."

Francis J. Hall, vice-president of the Central Iron & Steel Co., Harrisburg, Pa., and connected with the company for the past 20 years, has resigned, effective May 31.

John R. Johnson, who will receive his doctor's degree in June from the University of Illinois, has been awarded one of the Field scholarships to France. He will continue his research at the Sorbonne.

Hugo C. Larson, of the University of Illinois, has received a fellowship from the Scandinavian-American Foundation and will sail in June for Stockholm, where he will work in the Royal Technical Institute on the metallurgy of special steels.

F. J. Metzger was elected vice-president of the Air Reduction Co., Inc., in charge of research and development, at a meeting of the board on May 24.

Frank R. Miller has left the American Agricultural Chemical Co. after 38 years of service, to open an office as an "advertising engineer" in the Widener Building, Philadelphia, Pa.

H. Stirling Snell has just returned from a trip of inspection through some of the principal French chemical manufactories in the interest of William Heap & Sons, of Grand Haven, Mich., with which concern he is connected.

Charles R. Spare has been elected president of the American Manganese Bronze Co., Philadelphia, Pa., with plant in the Holmesburg Junction section. He organized the company about 15 years ago and is the inventor of the bronze manufactured by the company.

Prof. Haakon Styri, director of research, SKF Laboratories, Philadelphia, discussed before the Washington Chapter of the American Society for Steel Treating on May 22 the subject "Preparation and Heat-Treatment of Ball-Bearing Steel."

Obituary

Edward G. Locke, founder of the Locke Glazed Paper Co., Philadelphia, Pa., died at his home at Camden, N. J., on May 16, from paralysis. He was 65 years of age. Mr. Locke is survived by his wife and a daughter.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Our Service Department

A great many things come to an editor's desk and no small proportion of them are questions. Subscribers, advertisers and casual readers are constantly writing in for information and the editorial department of a technical magazine is looked upon as a depository replete with miscellaneous knowledge of practically every field of human endeavor. To some small extent, perhaps, this is justifiable, for in general the editor's experience is remarkably catholic and a wide range of informational sources is usually available to him.

CHEM. & MET.'S editorial staff is no exception to this rule and certainly if we are to judge from some of the appreciative letters which we have recently received from our readers, the practice has come to be regarded as a valuable part of the magazine's service to industry. CHEM. & MET. has gradually developed within its organization an informational bureau equipped to supply data on practically every phase of the chemical, metallurgical and allied industries. This service is offered to its readers with the single reservation that it is in no sense competitive with the admirable work of the professional consultant. In fact we consider it a part of our service to recommend to our inquirers the consulting chemists and engineers who are best qualified to handle the research problems that lie beyond the natural limitations of a gratuitous informational bureau. Technical problems concerning processes, producing operations and equipment are so closely related to editorial matter that they have always received special attention. Furthermore, our research department stands ready to co-operate in locating new sources and uses for materials and equipment.

Naturally the market editors receive a goodly share of these queries, for their field touches on the products of all our industries. In these letters from our readers it is the commercial and economic information about particular commodities that is most often sought. Latest statistics on production, consumption, imports and exports are in demand and in most instances they can be supplied without delay. Others of our readers are desirous of following the trend of prices over some definite period or in greater detail than is afforded by our weighted index number. And, too, we are often asked to review conditions affecting the market for an individual chemical or metallurgical product. Such factors as tariff changes, embargoes and strikes have a prevailing influence on market conditions, and it is our business to keep in touch with these developments.

Our service department has been designed to serve our readers and all are invited to make use of it. Pertinent inquiries will receive careful, intensive study and every effort will be made to supply reliable information bearing on the problems of the chemical and allied industries.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	157.72
Last week	160.49
May, 1917	222
May, 1920	279
April, 1918 (high)	286
April, 1921 (low)	140

The sudden recession of the index number during the past week has resulted from the lower prices quoted for several of the most important commodities on which the index is based. Thus the decline of ammonium sulphate, caustic soda and cottonseed and linseed oil was sufficient to cause a drop of almost 3 points. The fall in the case of linseed oil amounted to 4 cents on the gallon.

The Ten Per Cent Reduction in Freight Rates

Excessive transportation charges are generally regarded as one of the most important factors affecting costs in the chemical and allied industries. These are the industries that furnish most of the basic materials of commerce, and no small share of the delivered cost of their products is directly attributable to the freight rates. Particularly is this true in the case of the heavy chemicals and other bulky materials of comparatively low unit costs.

The general rate reduction of 10 per cent, announced by the Interstate Commerce Commission on May 24, is of more than usual significance, therefore, to the industries that make materials. This is evidenced by the fact that in extended investigation, which began last December and concluded March 15, the commission paid particular attention to such basic commodities as coal, iron and steel, cement, fertilizers, petroleum, paper and pulp and to miscellaneous chemical products such as the alkalis, creosote oil, explosives, glass, insecticides, naval stores, soda ash, etc.

The Commission's Findings

The commission found that on and after July 1, 1922, freight rates would be unreasonable to the extent that they may exceed the rates in effect Aug. 25, 1920, by specified percentages in the various rate groups of the country, so applied to make reductions in each group equivalent to 10 per cent. These percentages are as follows:

In the Eastern group, also between points in Illinois territory and between Illinois territory and the Eastern group, 26 per cent instead of the 40 per cent authorized in the last decisions.

In the Western group, and between the Western group and Illinois territory, 21.5 per cent instead of the 35 per cent previously authorized.

In the Southern and mountain-Pacific groups, 12.5 per cent instead of the 25 per cent previously authorized.

On interterritorial traffic, except as otherwise provided, 20 per cent instead of the 33⅓ per cent previously authorized.

These rates, in the opinion of the commission, will enable the railroads to earn a net return of 5.75 per cent upon the aggregate value of railway properties. This is a reduction of one-fourth of 1 per cent in the fair return authorized March 1, 1920. It is also pointed out that the 10 per cent reduction does not apply in the case of reductions which have been made since August, 1920, except in cases where reductions have been made for the purpose of equalizing rates and correcting inconsistencies.

Freight Problems in the Process Industries

The commission's report, which bears the title "Reduced Rates, 1922," contains a number of interesting references to the freight problems of the chemically controlled industries. Under the heading "Cottonseed Products, Vegetable Oils and Soap," the report makes the following comment:

There are about 750 cottonseed-oil mills in the cotton-growing territory of the South. They represent an investment of about 250 million dollars and crush 85 per cent of the cotton seed produced. The products are cottonseed oil, meal, hulls and linters. In 1921 this industry brought its costs down materially below those of 1920. About 500 of the mills were operated in the season 1921-22, 300 of them continuously. The failure to operate more nearly to capacity is attributed in part to high freight rates.

Soap moves for the most part in carlots from factories to distributing points, but there is also a considerable less-than-carload movement from factories. From dis-

tributing points the movement is in less than carloads. The principal raw materials used are fats, greases and oils. Caustic soda, soda ash, lime and borax are also largely used. The aggregate inbound and outbound tonnage of materials and product was estimated at 3,000,000 tons annually, much of it moving for considerable distances. Delivered prices of soap were said to be about 33⅓ per cent over those of 1914. The soap manufacturers asked that as soon as a reduction in rates is possible it be made horizontally in all rates.

The paper manufacturers asked for rate reductions not only on their finished product but on their raw materials such as woodpulp, coal, clay, sulphur, resin and tallow. Between 3 and 4 tons of these materials are required to produce 1 ton of newsprint. The principal contention of the papermakers was that the rates on paper from New England were relatively lower than those in effect from Western mills. The New England shippers urged the commission "to prescribe rates on newsprint paper not exceeding 80 per cent of the rates on book, printing and wrapping paper, with sixth-class rates as maxima, and further that reductions should be made from New England to Chicago and Western points, even though reductions were not made from the Western mills. They also contended that, if reductions are to be general, the rates from New England to points in the Eastern group should be lowered to a greater extent than rates from Western mills."

The commission declared, however, that the evidence does not warrant fixation of the proper rate relationship between these competing mills.

The report points out that the fertilizer industry is most seriously concerned with transportation charges for two reasons: (1) The manufacturer pays both the freight on his raw materials and the outbound charges on the finished product. (2) The price of fertilizer is very closely approaching its 1914 price. This is recognized by the commission, which reports on the situation as follows:

> The extent to which fertilizer is used is determined to a considerable degree by the farmer's ability to obtain credit. This is confirmed by the carriers. Local dealers or distributors have been accustomed at the beginning of the planting season to extend such credit to mature with the crops, in turn depending upon the fertilizer manufacturers for credit. Some of these manufacturers said that since the price to the farmer is practically upon a pre-war level, rate reductions must be made, and the benefit retained by them in order to enable them to continue the customary extension of credit, thereby indirectly benefiting the farmer. Others said that a reduction will immediately inure to the purchaser.
>
> The fertilizer for use in production of this year's crops has already moved, but the annual movement of raw materials into the fertilizer plants does not begin until May. Fertilizer manufacturers asked that reductions ranging from 20 to 25 per cent be made on fertilizer materials and that on fertilizer we prescribe for the southern group a distance scale of rates suggested by them.

The New York Market

New York, May 29, 1922.

Activity in the chemical market during the past week was limited to a few special items and a feature among these has been the recent strength of the prussiates. Both the soda and the potash salts have recorded new high levels for the year, with the former showing pronounced advance because of the scarcity of spot material. Caustic soda remained very firm for nearby shipments of standard brands. The export demand continues in good proportions from continental Europe, Italy and the Far East. British and French prices remain considerably above American prices and this condition is causing a demand for American goods. Soda ash continues along its former lines, with demand only moderate for domestic and export consumption. Permanganate of potash was a shade easier due to competition. Arsenic is showing the effect of renewed interest and the market was somewhat firmer. Copper sulphate continues very strong, with a steady demand for domestic consumption. There has been very little business done in the rest of the list and the general buying movement was quite irregular.

General Chemicals

Arsenic—Some improvement is recorded in this item from consuming quarters and sellers are asking 7¼@7½c. per lb. for spot and nearby shipments of the white powdered. Supplies are not very heavy and the market is set for an advance.

Barium Chloride—Dealers of spot material report a pronounced scarcity. Producers, however, are offering material at $95 per ton f.o.b. works. Quotations among resale dealers range around $100@$105 per ton. June delivery from abroad is held at $95 per ton.

Bleaching Powder—Domestic factors quote large drums at $1.60 per 100 lb., f.o.b. works. Imported goods remain unchanged at $1.65 ex-dock. The demand is only moderate.

Caustic Potash—Small-lot sales have been made around 6c. per lb. for the imported 88-92 per cent, but a conspicuous absence of round-lot trading was noted. Any additional inquiries will have a strengthening effect on spot prices.

Caustic Soda—Foreign inquiries covering a wide range continue to reach this market and the undertone is quite firm. Domestic shipments of standard brands are quoted at $3.85@$3.90 per 100 lb. f.o.b. New York. Large producers report a steady call for contract shipments.

Chlorate of Potash—Domestic makers quote 8c. per lb. for prompt shipment. Odd lots of imported material are on the market at 6¾@7c. per lb. The inquiry has shown no unusual activity during the past week.

Chlorate of Soda—Sales of spot material are reported by dealers, but only for small quantities at 6½c. per lb. Large lots can be shaded down to 6¼c. per lb. Leading producers quote the market at 6¾c. f.o.b. works. A moderate consuming inquiry is recorded.

Prussiate of Soda—The consuming industry has become more interested in this item during the past week, through reduced spot offerings and the steadily advancing prices. The tone of the market late in the week became exceptionally buoyant and several advances were recorded. Holders were asking 25c. per lb., with only a few odd tons available.

Sal Ammoniac—A few lots of imported white granular were on the market at 7c. per lb. Domestic goods were quoted at 8c. per lb. Gray offerings were not very liberal and most sellers were holding prices at 8c. per lb.

Waxes

Beeswax—The feature in the market was the strength in African Crude, which sold as high as 19½c. per lb. Stocks in all grades are rather light.

Carnauba Wax—Demand for this product was not very active, but prices held steady at primary centers. No. 3 North Country was offered at 16c. per lb. No. 2 North Country held around 25c. per lb.

Japan Wax—There were offerings on spot at 16½c. per lb., with nearby goods quoted at 16c. and futures at 15½c. per lb. The market was somewhat quiet and the general tone was barely steady.

Montan Wax—Supplies were very plentiful on spot and the market was irregular, ranging from 4c.@4½c. per lb.

Paraffin Wax — The domestic demand is up to expectations, but the export inquiry is very dormant and trading is rather quiet. Match wax is moving moderately, with leading dealers quoting 4¼@4½c. per lb. Crude scale, 122-124 deg. melting point, was offered at 2¼c. per lb. Fully refined, 123-125 deg. melting point, sold under 3c. per lb. during the week.

Naval Stores

Turpentine (Spirits) — While trading in general was rather quiet toward the latter part of the week, the advance in prices was sustained and the market closed at 95c. per gal, ex-yard. Supplies on spot were reported limited.

Rosins—Trading in the different grades was active during the past week and with the Southern market higher, prices in the local market advanced from 10@25c. per barrel. The market during the latter part of the week was quiet, but prices ruled steady.

The St. Louis Market

ST. LOUIS, MO., May 23, 1922.

There have been no changes of importance in the industrial chemical market in this locality since our last report. Business continues to increase and prices generally are very firm.

ALKALIS

The *caustic soda* market remains firm and fairly active, the demand for small lots being especially good. Prices have not changed any since our last report, but a gentle rise would not be altogether unexpected. *Soda ash* is remaining uniform both in price and quantity, no variations being felt either way in this market. *Sodium bicarbonate* has become somewhat stabilized since our last report, with no decline noted recently. *Sal soda* continues to move in its regular channels and at uniform prices as of our last report.

GENERAL AND SPECIAL CHEMICALS

Heavy mineral acids continue to move in a fair way. However, a much larger volume of business could be transacted if it were not for the fact that the steel mills are being restrained in their operations, due to the coal situation. One manufacturer reports a good demand from the fertilizer trade. *Citric acid* is still in good demand with no change in price. *Acid tartaric* and *cream of tartar* are beginning to show signs of improvement, and orders of larger volume are now passing. The market for *white arsenic powdered* has shown some slight improvement. Prices generally are firm and quoted at 6½@7c. f.o.b. New York. *Carbon bisulphide*, being a seasonable article, is now moving very freely. *Glycerine* continues weak and although the regular market quotation is 15c. in drums, a good-sized substantial contract was recently placed at less than 14½c. *Sodium fluoride* is now in better demand, with prices firm. *Sulphur* continues in stiff demand and prices need not be expected to drop. The present time is proper for placing large orders, since there is no indication of a decline. The prices quoted in our last report for *zinc sulphate* remain unchanged. However, an advance is anticipated owing to the increase in price for *zinc spelter*.

VEGETABLE OILS AND NAVAL STORES

Linseed oil has not changed since our last report and continues firm at $1.07 basis raw oil. It is rather unusual that the market on linseed oil should not fluctuate in two weeks, but the lack of contract inquiries probably accounts for this. *Turpentine* reached the remarkable height of $1.04 a few days ago, but is now back to $1. With the *rosin* market regaining its natural health, turpentine bids fair to hold up. *Castor oil* is unchanged. Prices firm and demand good.

PAINT MATERIALS

The recent sunshine has worked a wonderful improvement both in demand for material and in the attitude of the grinders. No price changes have been noted, but a fair amount of carload business on dry earth colors has been done recently, the purchasers seeking to get covered before the expected import duty goes into effect.

The Iron and Steel Market

PITTSBURGH, May 26, 1922.

Except for decided activity in connection with three important lines of steel consumption, the turnover in steel products is now light, much lighter than in March and April. The mills are well sold up for a couple of months or more, and buyers, with some exceptions, are well covered. The relation is such that the sellers have the advantage.

The three lines of steel consumption in which active buying at the present time is represented are the building of freight cars and motor vehicles and the erection of skeleton steel work. Freight car orders, having averaged, roughly speaking, about 15,000 cars a month since the first of the year, are still in evidence, even more strongly than in the first 2 or 3 months of the year. The buying is at about the average pace that obtained in the 10 years 1904 to 1913. The proportion of steel production passing to the railroads is, however, greatly reduced, for there is less steel called for by railroads in lines outside of freight cars, and the steel-making capacity is greatly increased.

Production of passenger automobiles this month will probably exceed 200,000 cars, an almost complete report for April having shown 196,412 cars, apart from 21,944 trucks. With steel required for accessories, equipment, etc., the automobile industry at large is probably consuming finished rolled steel at the present time at a rate of nearly if not quite 150,000 gross tons a month. Production of finished rolled steel at a rate of 2,300,000 or 2,400,000 gross tons a month.

In the past 2 months placing of fabricated steel contracts has been approximately equal to the fabricating shop capacity, while contracts in the first quarter of the year represented only a trifle over half the capacity, and the average for the year 1921 was 35 per cent.

STEEL PRICES STRONG

With steel production at only about 70 per cent of the full capacity, a market has been produced as strong as obtained before the war only when the mills were operating at 90 to 100 per cent. The coal strike, apparently, makes the difference.

Bars, shapes and plates are quotable at 1.60c. as the minimum of the regular market, and are by no means easy to buy at that price. Several mills are quoting $2 to $3 a ton more, and are probably booking some business, when prompt delivery is requisite. Particularly attractive orders for plates and shapes may possibly go at concessions, especially if, as in the case of the average freight car order, the negotiations were started long ago.

Hoops are being quoted at 2.25c. It is not long since that the market firmed up to 2c. Apparently the mills have larger delivery obligation than they thought they were taking when they were so eager to sell early in the year. Sheets and tin plates are very stiff at regular prices, while in sheets not a few mills are asking $5@$7 a ton extra.

The higher prices now ruling for steel do not increase profits. The familiar experience of its requiring several months of activity for the mills to dispose of low priced business is being repeated, hence there is particular interest in the subject of steel demand next Autumn. A continuance of present pressure for steel will result in reasonable profits. There is easily enough momentum to carry the mills through the summer, normally a dull period in the market.

PRODUCTION HEAVY

Steel ingot production is running at somewhat over 37,000,000 gross tons a year. Output last December was at a rate of 20,000,000 tons, the rate rising rapidly in 3 months, to about 35,000,000 tons April 1. Since then there has been a slight increase, despite the coal strike.

LOWER COKE PRICES

Connellsville coke, which advanced sharply about 10 days ago, had an equal drop early this week, and is now quotable at $3.25@$3.50 for steam grade. Dealers attribute the drop to Secretary Hoover's interest in coal prices, not that producers voluntarily reduced their asking prices, but that some Eastern buyers, expecting lower prices, withdrew from the market, and the relation between demand and offerings effected the change.

Connellsville coke, on the other hand, has advanced nearly a dollar a ton in the week. Offerings have been very limited and at times there has been practically no inquiry, but a few days ago buying orders began to appear, in connection with the possible resumption of two steel works furnaces. The makers involved appear to be getting such premiums for their steel as to be able to pay rather fancy prices for coke, especially since furnace grade is now $7@$7.50.

The pig iron market remains stagnant, inquiry being almost absent. Prices are practically nominal, at $26 for bessemer, $25 for basic and $24 for foundry, f.o.b. valley furnaces.

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.15 — .16
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.50 — .55
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.50 — .55
Beta-naphthol, tech	lb.	.25 — .27
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.53 — .55
Cresylic acid, 95-97%, dark, in drums	gal.	.48 — .50
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.65 — .70
Dimethylaniline	lb.	.36 — .38
Dinitrobenzene	lb.	.22 — .25
Dinitroclorbenzene	lb.	.22 — .24
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .65
H-acid	lb.	.85 — 1.00
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.09 — .11
Monoethylaniline	lb.	1.05 — 1.25
Naphthalene crushed, in bbls.	lb.	.06 — .06¼
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.08 — .08
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17
Ortho-amidophenol	lb.	2.40 — 2.50
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.70 — .75

Ortho-nitro-toluene	lb.	$0.12 —	$0.15
Ortho-toluidine	lb.	.14 —	.18
Para-amidophenol, base	lb.	1.25 —	1.30
Para-amidophenol, HCl	lb.	1.30 —	1.35
Para-dichlorbenzene	lb.	.13 —	16
Paranitroaniline	lb.	.75 —	.77
Para-nitrotoluene	lb.	.60 —	.70
Para-phenylenediamine	lb.	1.55 —	1.60
Para-toluidine	lb.	1.00 —	1.10
Phthalic anhydride	lb.	.35 —	.38
Phenol, U. S. P., drums	lb.	.14 —	15
Pyridine	gal.	1.75 —	2.75
Resorcinol, technical	lb.	1.30 —	1 35
Resorcinol, pure	lb.	1.75 —	1.80
Salicylic acid, tech., in bbls	lb.	.25 —	.25½
Salicylic acid, U. S. P	lb.	.26 —	.26½
Solvent naphtha, water-white, in drums, 100 gal	gal.	.25 —	.28
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.10 —	.12
Sulphanilic acid, crude	lb.	.24 —	.26
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	.33 —	.35
Xylene, commercial, in tank cars	gal.	.30 —	....

Waxes

Prices based on original packages in large quantities.

Bayberry Wax	lb.	$0 20 —	$0.21
Beeswax, refined, dark	lb.	.26 —	.28
Beeswax, refined, light	lb.	.30 —	.32
Beeswax, white pure	lb.	.35 —	.40
Candellila, wax	lb.	25 —	.26
Carnauba, No. 1	lb.	.45 —	.46
Carnauba No. 2, North Country	lb	.25 —	.25½
Carnauba, No. 3, North Country	lb.	.16 —	.16½
Japan	lb.	.16½ —	.17
Montan, crude	lb.	.04 —	.04½
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.04¼ —	....
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.02⅜ —	....
Paraffine waxes, refined, 118-120 m.p.	lb.	.02 —	.03
Paraffine waxes, refined, 125 m.p.	lb.	.03 —	.03½
Paraffine waxes, refined, 128-130 m.p.	lb.	.04 —	.04½
Paraffine waxes, refined, 133-135 m.p.	lb.	.04¼ —	.04¾
Paraffine waxes, refined, 135-137 m.p.	lb.	.05 —	.05½
Stearic acid, single pressed	lb.	.09 —	.09¼
Stearic acid, double pressed	lb.	.09½ —	.09¾
Stearic acid, triple pressed	lb.	.10½ —	.10¾

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl	280 lb.	$5.40 —	$5.55

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

BATESVILLE—The American Manganese Co. has preliminary plans under way for the construction of new mills for considerably increased output. The company has an extensive tract of manganese ore in the Batesville-Cushman district and is arranging for extensive development. To provide funds for expansion, a bond issue of $250,000 is being sold. Norman E. Brokaw is president.

EL DORADO—The El Dorado Oil & Pipe Line Co. has work under way on the rebuilding of its oil refinery, recently destroyed by fire, and will install considerable new machinery. It is expected to have the plant ready for service at an early date.

California

SAN PABLO—The San Pablo Pottery Co. will build two new kilns at its plant and make other extensions.

OAKLAND—The Westgate Metal Products Co., recently organized with a capital of $2,500,000, to manufacture iron, steel and other metal castings, has tentative plans under consideration for the erection of a new plant. A. T. Burch, 78 El Camino St., heads the company.

Connecticut

HAMDEN—The Kiss Brothers Co., Meriden, manufacturer of pottery products, has acquired the local plant of the Joseph Dixon Crucible Co., and will remodel for a new pottery. Clay properties in this section have also been secured. The company will install necessary equipment and occupy the plant at an early date.

Delaware

WILMINGTON—The Wilmington Sugar Refining Co. has awarded contracts for additional buildings at its new local refining plant, now in course of erection, comprising a 4-story melting and washing building, 60x90 ft., and 1-story power plant, 95x150 ft., to be located at Christiana Ave. and B St. Harding & Craig, Buffalo, N. Y., are contractors. W. J. Wayte, Inc., 125 East 46th St., New York, N. Y., is engineer.

WILMINGTON—James J. O'Neill, manufacturer of leather, has acquired property now occupied under lease on Commerce St., near Dock St., heretofore held by E. Paul du Pont, for a consideration of $55,000, as a permanent site for his leather tannery. Improvements, it is said, will be made in a number of buildings.

Florida

BRADENTOWN—J. H. Humphries is planning for the establishment of a new plant on local site for the manufacture of commercial fertilizer products.

Georgia

ATLANTA—The Standard Sanitary Mfg. Co., 295 Peachtree St., manufacturer of sanitary earthenware products, has preliminary plans under way for the erection of an addition.

RUTLEDGE—The Rutledge Oil Co. is planning for the rebuilding of the portion of its mill, recently destroyed by fire with loss estimated at close to $150,000, including equipment. The company is operated by Stanton & Wofford, Social Circle, Ga.

Illinois

CHICAGO—The Chicago Pottery Co., 1924 Clybourn Av., has completed plans for the erection of a 2-story addition, 113x190 ft., and will commence erection at an early date. L. E. Russell, 25 North Dearborn St., is architect.

LEMONT—The Illinois Pure Aluminum Co. has awarded a contract to E. W. Sproul, Pershing Road and Robey St., Chicago, for the erection of a 1-story addition, to cost about $35,000. Frank D. Chase, Inc., 645 North Michigan Ave., Chicago, is engineer.

Kansas

TOPEKA—The Sunflower Oil & Refining Co. is reported to be planning for the rebuilding of the portion of its plant recently destroyed by fire with loss of about $40,000.

Louisiana

CEDAR GROVE—The Gulf States Chemical Co., a subsidiary of the National Window Glass Co., is planning for the early operation of its new local plant, now nearing completion, for the manufacture of insect powders and kindred chemical specialties. D. N. Skinner is secretary.

Maryland

BALTIMORE—Ernest E. Stanley, Calvert Bldg., is organizing a new company for the establishment of a plant for the manufacture of chemical products. A building has been leased at Biddle St. and Madison Ave., for the proposed new works.

BALTIMORE—The Argol Sulphite Co., has plans nearing completion for the erection of a new 1-story plant, 40x100 ft., at Curtis Av. and Birch St., and will break ground at an early date.

BALTIMORE—The Edward Richardson Brass Co., 318 North Holliday St., has acquired through its president, Edward Richardson, the former plant of the Zirconium Co. of America, Monument and 11th Sts., recently offered at public auction. The works comprise a group of buildings, with power house, machine shop, etc., and will be used by the new owner. The purchase price is said to be $38,500.

Massachusetts

DANVERS—The Danvers Welt & Leather Co. is considering tentative plans for the rebuilding of the portion of its plant recently destroyed by fire with loss estimated at about $40,000, including equipment and stock.

Michigan

SAGINAW—The Aero Cushion Inner Tire & Rubber Co., 907 Ford Bldg., has plans nearing completion for the erection of a new 1-story plant for the manufacture of tires and other rubber products, 80x200 ft., estimated to cost about $75,000, including equipment. J. J. O'Shaughnessy is general manager.

DETROIT—The Detroit Soda Products Co., 9077 West Jefferson St., has awarded a general contract to the Bennage-McKinstrie Co., 1460 Baldwin Ave., for the erection of a 2-story plant addition, 60x80 ft. L. B. Alger is president.

Montana

COLUMBIA FALLS—The Cyanide Gold Mining Co. has preliminary plans in preparation for the erection of a new mill and cyanide plant, with capacity of about 150 tons a day. It is proposed to commence work at an early date and have the plant ready for service before the close of the year. James La Fountain and T. J. Hollinger head the company.

New Jersey

PERTH AMBOY—The Novo Laboratories, Inc., 651 Catherine St., will commence the immediate erection of a 1-story plant addition for grinding, mixing, etc., to cost about $25,000. Contract for the building and certain machinery has been awarded. The structure will provide about 2,500 sq.ft. of floor space.

TRENTON—The Clay Products & Mining Corp., recently organized, is arranging to take over the property of the Southern Refractories & Kaolin Co., Fort Payne, Ala. A number of improvements will be made, with extensions for increased production. The company is capitalized at $1,500,000, and is headed by Richard M. J. Smith and W. P. Cubberly; it is represented by Samuel C. Kulp, 150 East State St., Trenton.

GARWOOD—Three 1-story foundry buildings will be erected by the National Boiler Co., South Ave., estimated to cost in excess of $30,000. Hooper & Co., 116 Market St., Newark, are architects.

MENDHAM—Leo Robinson, borough clerk, will take bids until 8 p.m., June 12, for the construction of a filter plant and appurtenances at the waterworks.

New York

BUFFALO—The Buffalo Smelting Co. has acquired property, 276x301 ft., on Tonawanda St., as a site for the erection of a new plant for the smelting and refining of copper, brass and other metals. It will consist of a main building, 50x90 ft., and smaller adjoining structures. George Giessen is president.

ALSEN—The Hudson Valley Portland Cement Corp. has work under way on the third unit of its finishing mill, and plans to have the structure equipped and ready for service at an early date. It is proposed to develop an annual output of 1,140,000 bbl. at the plant. To provide for expansion, additional working capital, etc., the company has arranged for a bond issue of $1,000,000.

PORT JERVIS—Swinton & Co., 47 Main St., will build a new 1-story foundry at their stove works, 72x150 ft., to cost about $40,000, including equipment. Work will be commenced at once. Robert Livingston, 2 Rector St., New York, is engineer. J. D. Swinton is head.

North Carolina

ASHEVILLE—The Felstone Co., 326 Haywood Bldg. recently organized with a capital of $100,000, to manufacture concrete and cement products, has plans under way for the erection of a new 1-story plant, 54x100 ft., on site selected near Biltmore, N. C. It will cost close to $30,000, including equipment. W. L. Gravatt, Jr., is secretary.

OLD FORT—The Old Fort Pottery Works, Inc., recently organized, has preliminary plans in preparation for the erection of a new local plant for the manufacture of earthenware specialties. J. A. Lowery and J. H. Young head the company.

Ohio

CINCINNATI—The Triangle Paper Co., 943 West 6th St., plans for the rebuilding of the portion of its plant destroyed by fire, May 8, with loss estimated at about $30,000.

Oklahoma

IDABEL — The City Council has plans under way for the construction of a new filtration plant, in connection with a new pumping plant at the waterworks, to cost about $150,000. The Benham Engineering Co., Gumbel Bldg., Kansas City, Mo., is engineer.

Oregon

SALEM—The Oregon Pulp & Paper Co. is planning for extensions and improvements in its plant to cost about $55,000. C. F. Beyerl is general manager.

Pennsylvania

PHILADELPHIA—The H. H. Barton & Son Co., 109 South 3rd St., manufacturer of sandpaper and kindred specialties, will soon take bids for the erection of a 2-story plant addition. 40x100 ft. Tilden & Register, 1525 Locust St., are architects. Charles B. Barton is president.

MARCUS HOOK—Fire, May 16, destroyed a portion of the grease-manufacturing plant at the refinery of the Sun Oil Co., Finance Bldg., Philadelphia, with loss estimated at about $60,000, including equipment and stock.

EAST STROUDSBURG—The Scott-Warman Glass Co., manufacturer of bottles, will commence the immediate rebuilding of its plant, partially destroyed by fire last January, with loss approximating $150,000. The new structure will cost close to a like amount.

South Carolina

GREENVILLE—The Gray & Son Glass Co., Falls Creek, Pa., manufacturer of rough and ribbed glass, is considering the erection of a new branch plant at Greenville. George R. Gray is president.

Tennessee

NASHVILLE—The Hermitage Portland Cement Co., Chattanooga, has acquired a portion of the Old Hickory plant of the government and is reported to be planning for the construction of a large cement mill on

the site. Present structures will be remodeled and a number of new buildings erected. It is proposed to develop a daily capacity of 2,000 bbl. The new mill will cost in excess of $1,000,000, with machinery. John C. Vance is president.

Texas

CLARKSVILLE—The Texas Petroleum Co., Fort Worth, W. W. Fisher, president, has plans nearing completion for the construction of a new local refinery of two-unit type, with initial capacity of about 500 bbl. a day.

LAREDO—The Texas-Mexican Oil & Refining Co., Milno Bank Bldg., recently organized with a capital of $150,000, will soon commence the construction of the first unit of its proposed plant on local site, with output of 500 bbl. a day, estimated to cost about $90,000, including equipment. J. N. Galbraith is president.

Washington

HILLYARD—The Western Materials Co., Valley, Wash., operating local magnesite properties, is planning for the erection of a new plant at Hillyard for the manufacture of magnesite cement, estimated to cost about $35,000. Negotiations are under way for a site.

New Companies

THE CARRIER CHEMICAL CO., Nitro, W. Va., has been incorporated with a capital of $150,000, to manufacture chemicals and chemical byproducts. The incorporators are C. F. Carrier, Jr., Archibald Krieg and M. T. Davis, Jr., all of Charleston, W. Va.

THE CROW CHEMICAL CO., Irvington, Newark, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are Joseph Walsh and Walter Runge, 17 Stengel Ave., Irvington.

THE GRAND RAPIDS BYPRODUCTS CO., Grand Rapids, Mich., has been incorporated with a capital of $50,000, to manufacture soaps, glue, fertilizer products, etc. The incorporators are William D. Batt, Peter D. Mohrhardt and Victor J. Mollers, all of Grand Rapids.

THE BOSTON PRINTING INK CO., Boston, Mass., has been incorporated with a capital of $50,000, to manufacture inks and kindred products. Zenas R. Taylor is president; and Daniel S. Schneider, 769 Morton St., Mattapan, Mass., is treasurer.

THE EQUITY PETROLEUM CORP., Wilmington, Del., has been incorporated under state laws, with capital of $10,000,000, to manufacture petroleum products. The company is represented by the Delaware Charter Co., Ford Bldg., Wilmington.

THE CAPITOL PRODUCTS CORP., Albany, N. Y., has been incorporated with a capital of $10,000, to manufacture paints, oils, etc. The incorporators are E. H. Brown, P. J. McLure and R. B. Streeter. The company is represented by M. H. Messimer, Albany.

THE STATE PAPER CO., Zanesville, O., has been incorporated with a capital of $100,000, to manufacture paper products. The incorporators are N. B. and William W. Hanlon, Zanesville.

THE U. S. DRYER & MACHINERY CO., York, Pa., has been incorporated with a capital of $150,000, to manufacture double shell driers of the rotary type. William J. Kuntz is general manager.

THE GILL CHEMICAL CO., Newark, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are L. S. Kochler, K. L. and Louis E. Graf, 439 Riverside Ave., Newark.

THE HAYS CORP., Seattle, Wash., has been incorporated with a capital of $5,000, to manufacture rubber products. The company is headed by Winfield R. Smith, Alaska Bldg., Seattle.

THE STANDARD FOUNDRY & MFG. CO., Kansas City, Mo., has been incorporated with a capital of $250,000, to manufacture iron and steel and other metal castings. The incorporators are W. H. Simpson, J. B. Harden and H. H. Akers, all of Kansas City.

PULVER & WALDMAN, INC., New York, has been incorporated with a capital of $5,000, to manufacture chinaware specialties. The incorporators are F. and S. Pulver and L. Walman. The company is represented by Max Gelles, 1140 Broadway, New York.

THE DECAMP CONSOLIDATED GLASS CASKET CO., Blackwell, Okla., has been incorporated under Delaware laws, with a capital of $25,000,000, to manufacture glass products. The incorporators are James W. DeCamp, Blackwell; F. H. Butehorn, New York; and Hilbert B. Mattheson, Orange, N. J. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del.

THE ROBINHOOD FELDSPAR CO., Robinhood, Me., has been chartered under state laws, to operate a plant for the production of commercial feldspar. Paul Nash is president, and S. M. Neff, treasurer, both of Robinhood.

THE VARCOTE CO., 40 East Kinzie St., Chicago, Ill., has been incorporated with a capital of $5,000, to manufacture paints, stains, varnishes, etc. The incorporators are W. J. Rankin, B. Z. Hazlett and George H. Johnston.

THE RED CROSS CHEMICAL CO., Fall River, Mass., has filed notice of organization to manufacture chemical products. Martini Barrette, 91 Oak Grove Ave., Fall River, heads the company.

THE FI-BESTOS CO., New York, N. Y., has been incorporated under Delaware laws, with capital of $100,000, to manufacture asbestos products. The incorporators are Joseph Sandler, David T. Lotwin and Nathan Frankel, New York. The company is represented by Boyce & Magee, Dover, Del.

THE ESSENTIAL OIL CO. OF AMERICA, Tavares, Fla., has been incorporated with a capital of $25,000, to manufacture essential oils. E. S. Burleigh is president; S. C. Colley, vice-president; and B. W. Hunt, secretary, all of Tavares.

THE AMERICAN RUBBER & BRASS CO., 203 West Lake St., Chicago, Ill., has been incorporated with a capital of $20,000, to manufacture brass specialties, rubber goods, etc. The incorporators are E. A. and Charles L. Brower, and Arthur J. Cordell.

THE EMLET-WINEBRENNER CO., Hanover, Pa., has been incorporated with a capital of $30,000, to manufacture chemicals, chemical byproducts, drugs, etc. John M. Emlet, Hanover, is treasurer.

THE NULOID CORP., Wilmington, Del., has been incorporated under state laws, with a capital of $10,500,000, to manufacture celluloid and other composition products. The company is represented by the Corporation Service Co., Equitable Bldg., Wilmington.

THE H. P. CHANDLEE SONS CO., 112-14 West Lombard St., Baltimore, Md., has been incorporated with a capital of $200,000, to manufacture chinaware, glass products, etc. The incorporators are George M. and Theodore M. Chandlee, and Jesse Englar.

THE ANACOCO OIL & REFINING CO., Lake Charles, La., has been incorporated with a capital of $200,000, to manufacture refined petroleum products. The incorporators are B. T. Head, Lake Charles; and T. R. Sutherland, Shreveport, La.

THE ELLA SINGER CO., Atlantic City, N. J., has been incorporated with a capital of $125,000, to manufacture chemicals and chemical byproducts. The incorporators are A. C. Chism, William J. Riley and Ella Singer, 143 South Virginia Ave., Atlantic City.

THE CHEMICAL PRODUCTS CO., INC., 837 Equitable Bldg., Baltimore, Md., has been incorporated with a capital of $10,000, to manufacture chemicals and byproducts. The incorporators are Edward C. Hamilton, B. G. Hamilton and Byron R. Webb.

VERNON BROTHERS & CO., Pittsburgh, Pa., are being organized under state laws by Lester B. Vernon and W. R. Cole, to operate a metal smelting and refining plant. Application for a state charter will be made on June 6. The company is represented by George B. Berger, 1737 Oliver Bldg., Pittsburgh.

THE DUNN CONSOLIDATED OIL CORP., Wilmington, Del., has been incorporated under state laws with capital of $6,000,000, to manufacture refined petroleum products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE DONOVAN PACKING & RUBBER CO., Philadelphia, Pa., has been incorporated with a capital of $6,000, to manufacture rubber specialties. S. J. Donovan, 211 Bainbridge St., Philadelphia, is treasurer.

THE TWIN FALLS BINDER BOARD MILLS, INC., Scotch Plains, N. J., has been incorporated with a capital of $10,000, to manufacture paper composition products. The incorporators are David Robinson, Harry S. Sherman and Max Rosenthal, Scotch Plains.

THE OLSTEIN CO., New York, N. Y., has been incorporated with a capital of $5,000, to manufacture oils, paints, etc. The incorporators are R. and S. Olstein, and M. W. Goodman. The company is represented by Levinson & Felnsod, 277 Broadway, New York.

THE INTERNATIONAL CARBON CORP., Wilmington, Del., has been incorporated under state laws with a capital of $32,500,000, to manufacture carbon products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE SMITH ALSOP-BLOOMINGTON PAINT CO., 110 East Front St., Bloomington, Ill., has been incorporated with a capital of $20,000, to manufacture paints, varnishes, oils, etc. The incorporators are Darrel W. Thompson, Guy W. Frederick and Edward A. White.

THE OWENS PETROLEUM CO., Cameron, Tex., has been incorporated with a capital of $30,000, to manufacture petroleum products. The incorporators are E. L. and J. R. Mays, and J. S. Owens, all of Cameron.

THE WILCOX-WALTER-FURLONG PAPER CO., Philadelphia, Pa., has been incorporated with a capital of $75,000, to manufacture paper products. E. T. Walter, Jr., 4701 Wayne Ave., Philadelphia, is treasurer.

THE TUC TOR METAL CORP., New York, N. Y., has been incorporated with a capital of $200,000, to manufacture metals and metal alloys. The incorporators are E. H. Foster, H. E. Brown and W. M. Smith. The company is represented by Van Vorst, Marshall & Smith, 25 Broad St., New York.

THE NATIONAL FLOOR TILE CO., Mobile, Ala., has been chartered with a capital of $144,000, to manufacture ceramic floor and wall tile. The company is headed by W. D. Dellingrath, Mobile.

THE EXCELSIOR PAPER CO., Room 911, 11 South LaSalle St., Chicago, Ill., has been incorporated with a capital of $150,000, to manufacture paper products. The incorporators are L. D. Green, David Alexander and S. Rubin.

THE PENNSYLVANIA OIL CORP., Pittsburgh, Pa., has been incorporated under Delaware laws, with a capital of $100,000, to manufacture petroleum products. The incorporators are George J. Young, C. E. Arnold and William Devlin. The company is represented by the Capital Trust Co. of Delaware, Dover, Del.

THE TIDEWATER FOUNDRIES CORP., Jersey City, N. J., has been incorporated with a capital of $10,000, to manufacture iron, steel and other metal castings. The incorporators are E. Mead Whipple, Franklin L. Whitney and Purley C. Butterfield, 170 1st St., Jersey City.

THE PITTSBURGH ABRASIVE CORP., Pittsburgh, Pa., has been incorporated under Delaware laws with capital of $600,000, to manufacture abrasive products. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington, Del.

THE HARBOR OIL CORP., Eldorado, Ark., has been incorporated under Delaware laws with capital of $1,000,000, to manufacture petroleum products. The incorporators are S. Williams, L. T. Langston and O. J. Lockhart. The company is represented by the Delaware Registration Trust Co., 900 Market St., Wilmington, Del.

THE TRINITY PRODUCTS CORP., New York, N. Y., has been incorporated with a capital of $10,000, to manufacture stainless steel. The incorporators are R. F. Heiles, J. Pfaff and M. T. Quinn. The company is represented by C. M. Davis, 2 Rector St.

Capital Increases, etc.

THE NATIONAL ROSIN, OIL & SIZE CO., 155 North Clark St., Chicago, Ill., has filed notice of increase in capital from $50,000 to $100,000.

JOHN W. MASURY & SON, 50 Jay St., Brooklyn, N. Y., manufacturers of paint, etc., have filed notice of increase in capital from $150,000 to $250,000.

THE VIRGINIA-CAROLINA CHEMICAL CO., Richmond, Va., has disposed of a bond issue of $22,500,000, a portion of the proceeds to be used for expansion, additions to working capital, etc. C. G. Wilson is president.

THE CLAY BRICK CO., Grand Rapids, Mich., has filed notice of dissolution under state laws.

THE GORDON PETROLEUM CO., Eastland, Tex., has filed notice of increase in capital from $75,000 to $120,000.

THE SHOPE CONCRETE BRICK CO., Las Cruces, N. M., has filed notice of organization to operate in Texas, with capital of $30,000, and headquarters at El Paso. The company is represented by J. M. Ireland, El Paso.

THE AETNA POWDER CO., Gary, Ind., has filed notice of dissolution under state laws.

THE COLUMBIA SUGAR CO., Bay City, Mich., operating branch refineries at Mount Pleasant, Mich., and Paulding, O., is disposing of a bond issue of $1,750,000, the proceeds to be used for expansion, general operations, etc. John C. Ross is president.

THE GIBSON OIL CO., Vincennes, Ind., has

filed notice of increase in capital from $250,000 to $500,000.

THE JACK DALTON OIL CO., Mineral Wells, Tex., has filed notice of increase in capital to $1,000,000 for expansion.

THE CLARK PAPER CO., 541 Ridge St., Newark, N. J., has filed notice of dissolution under state laws.

THE COPLAY CEMENT MFG. CO., Coplay, Pa., has called a special meeting of stockholders on June 15, to vote on an increase in capital from $500,000 to $1,250,000.

THE W. R. HOLLINGSHEAD CHEMICAL CO., Utica, N. Y., has filed an involuntary petition in bankruptcy, with liabilities stated at $80,000.

THE MATHIESON ALKALI WORKS, 25 West 43rd St., New York, N. Y., with plant at Providence, R. I., has acquired the plant and business of the Commonwealth Chemical Corp., Newark, N. Y., and will merge the property with its organization.

The plant and property of the STRONGCORD TIRE & RUBBER CO., Oak Hill Road, Evansville, Ind., will be sold by Henry B. Walker, receiver.

THE JOHN B. LOVE CHEMICAL CO., Wilmington, Del., has been incorporated under state laws with a capital of $250,000, to manufacture chemicals and chemical byproducts. The company is represented by the Delaware Charter Co., 904 Market St., Wilmington.

Industrial Developments

GLASS—The Graham Glass Co., manufacturer of bottles and hollowware, is arranging for the immediate resumption of production at its plant at Loogootee, Ind., following a shutdown for more than a year past. Employment will be given to more than 150 operatives.

The Potomac Glass Co., Cumberland, Md., started operations, May 22, in the new addition to its local blown-glass works, giving employment to about 200 workers as well as a number of apprentices, making a total of over 450 operatives at the entire plant. The addition represents an investment of $125,000. A new etching plant is being completed and will be placed in service at an early date. The plant is now running full.

Blown-glass plants at Millville, N. J., and vicinity are contemplating an increase in working hours from 8 to 9 hours a day.

LEATHER—The American Hide & Leather Co. has adopted full-time operations at its Sheboygan, Wis., tanning plant, working on heavy upper leather. The Ballston Spa, N. Y., tannery of the company is running at 100 per cent on patent leather and colored side leathers. At Chicago, Ill., operations have been increased at the local tannery to about 80 per cent of capacity for side and calf leathers. The Lowell, Mass., works are now operating at about 50 per cent of normal, recently resuming operations after a shut down.

The Central Leather Co., New York, N. Y., is increasing operations at its plants.

The Foucar Leather Co., Woburn, Mass., is advancing production from 1,000 to 1,400 sides of patent leather daily.

RUBBER—The B. F. Goodrich Co., Akron, O., has advanced production about 25 per cent since the first of May, increasing the operating schedule to a full 5-day week. Additional men will be employed.

The Seiberling Tire & Rubber Co. is increasing operations at its plants at New Castle, Pa., and Barberton, Ohio.

PAPER—The Riordan Co. is increasing operations at its pulp mill at Ticonderoga, N. Y., while the lumber mill of the company at Calumet, Mich., is running full under day and night shifts. The Kipawa paper mill of the company has increased production and is now operating on a basis of 150 tons a day, or close to capacity. The Hawkesbury mill is running on a basis of 100 tons a day, against a full capacity rating of 125 tons.

The Tonawanda Board & Paper Co., North Tonawanda, N. Y., is planning for the early resumption of operations, following a shut down for about a year past.

IRON AND STEEL—The Carnegie Steel Co. has resumed operations at its Farrell Works, Sharon, Pa., with blast furnace and thirteen open-hearth mills, following a shutdown from March, 1921. The last units of the plant at Mingo, O., have been placed in operation, making all mills of the company on the producing list with the exception of those at Columbus and Bellaire, O. The plants are developing 80 per cent of the productive capacity of the company for the first time in more than a year.

The Woodstock Operating Corp., Anniston, Ala., has blown in its blast furnace at La Follette, Tenn., following a shutdown for nearly two years. The company is reported to be arranging for the early resumption of production at its furnace at Anniston.

The American Rolling Mill Co., Middletown, O., is arranging for the early operation of two additional sheet mills at its plant, making twenty-nine such mills on the producing list, as compared with seventeen mills just before the depression in 1921. About 300 men have been added to the working force during the past three weeks.

The Struthers Furnace Co., Youngstown, O., will blow in its 500-ton blast furnace about the middle of June, following a suspension for 18 months past. The unit is being prepared for lighting.

The Eastern Steel Co. has resumed operations at its open-hearth plant at Pottsville, Pa., after a shutdown for 18 months. It is expected to be running full, giving employment to a normal working force at an early date.

The Shenango Furnace Co., Sharpsville, Pa., has blown in another blast furnace at its local plant.

The United States Steel Corp. has blown in another blast furnace at its Gary, Ind., plant, making eighteen out of twenty-seven furnaces now on the producing list. It is expected to place additional units in service at an early date.

The Midvale Steel & Ordnance Co. is arranging to blow in a second stack at its Coatesville, Pa., works early in June.

The Sloss-Sheffield Steel & Iron Co. has blown in its second blast furnace at North Birmingham, Ala., following a suspension for a number of months. The company plans to blow in its Birmingham city furnace early in June.

The Sharon Steel Hoop Co., Sharon, Pa., has resumed operations at all finishing mills at the local plant.

MISCELLANEOUS—The Davison Chemical Co., Baltimore, Md., is increasing production at its local plant in the sulphuric acid and other departments.

With practically all cement mills in the Lehigh Valley district of Pennsylvania running at capacity, the highest shipment for the year of 50,000 bbl. in one day was recorded on May 19. A large part of the distribution came from the plant of the Lehigh Portland Cement Co., Allentown.

Manufacturers' Catalogs

ADAM HILGER, LTD., 75A Camden Road, London, N. W. 1, England, calls attention to a bulletin illustrating and describing the Hilger chemical spectrometer designed for chemical analysis.

THE SUPERHEATER CO., New York, has just received from the press Bulletin T1, on superheaters for stationary power plants. This bulletin explains in detail the latest features of the Elesco superheater.

THE PACIFIC FOUNDRY CO., San Francisco, Cal., has published a bulletin on Corrosiron which covers the use of this acid-resisting metal for drain pipe and fittings.

THE TABER PUMP CO., Buffalo, N. Y., in Bull. 131 gives some helpful hints on the application of rotary pumps, also a friction table and conversion scale. This bulletin should be an aid to industrial plants interested in rotary pumps.

THE GRIEBEL INSTRUMENT CO., Carbondale, Pa., has issued an attractive catalog, No. 21, listing glassware for laboratory and scientific purposes.

W. S. ROCKWELL CO., New York, calls attention to Bull. 242, on the influence of method of heating and handling on quality and cost of heat-treated products. This bulletin is a supplement to the series of educational papers previously issued and is intended to illustrate the variety of methods of applying the principles of proper heating and handling to different manufacturing requirements and shop conditions. Another bulletin recently issued is No. 243, on stationary and tilting crucible melting furnaces.

THE SANDVIK STEEL, INC., New York City, has issued a 26-page booklet on steel belting. It contains information as to how the steel belt is applied to solving conveying problems, its efficiency, economy, etc. Anyone interested can obtain a copy of this booklet, No. 18-T, by writing to Sandvik Steel, Inc., 233 Broadway, New York City.

THE HARBISON-WALKER REFRACTORIES CO., Pittsburgh, Pa., has issued a leaflet on Thermolith, the all-temperature fire cement.

THE REPEL-ARC FURNACE CO., Indianapolis, Ind., in Bull. 301 gives facts about the Repel-arc furnace.

THE GRISCOM-RUSSELL CO., New York, has published Bull. 904, on the multiwhirl cooler.

THE SPENCER LENS CO., Buffalo, N. Y., has issued a bulletin on a selection of Spencer products for commercial and industrial laboratories. This list has been selected from the company's larger catalog and with special consideration of workers in industrial and chemical laboratories.

THE CUTTER CO., Philadelphia, Pa., has issued a booklet illustrating and describing I-T-E circuit breakers as applied to the protection of electrical and associated machinery in central stations.

THE ESTERLINE-ANGUS CO., Indianapolis, Ind., in Bull. 422, on "Getting Business With Graphics," discusses the possibilities of the use of graphic records in the sale of technical products.

HERMAN A. HOLZ of New York has issued a four-page folder on "Important Progress in the Calorimetry of Gases."

THE INDUSTRIAL AIR ENGINEERING CO., Elyria, O., in an 8-page booklet illustrates and describes the Industrial Air Purifier and Dust Collector.

THE ROLLER-SMITH CO., New York, has issued two new bulletins. No. 820 illustrates and describes PV ammeters and voltmeters and COD indicators and Bull. 560 illustrates and describes inclosed circuit breakers.

CENTURY WOOD PRESERVING CO., Pittsburgh, Pa., has issued a new bulletin on "Adzing and Boring Cross-Ties."

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold a joint meeting with the Pacific Division of the Association, on the occasion of the annual meeting of the latter, in Salt Lake City, June 22 to 24.

AMERICAN ASSOCIATION OF ENGINEERS will hold its eighth annual convention at Salt Lake City, Utah, June 4-6.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Pittsburgh, Pa., Sept. 5 to 9.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 21, 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, Canada, June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its nineteenth annual meet- at Bigwin Inn, Bigwin Island, in the Lake of Bays district, Ontario, Canada, on June 21, 22 and 23.

AMERICAN OIL CHEMISTS' SOCIETY will hold its annual meeting at the Grunewald Hotel, New Orleans, La., June 5 and 6.

AMERICAN PULP AND PAPER MILL SUPERINTENDENTS ASSOCIATION will meet in Kalamazoo, Mich., June 1, 2 and 3.

AMERICAN SOCIETY FOR STEEL TREATING will hold its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

ANNUAL SAFETY CONGRESS OF THE NATIONAL SAFETY COUNCIL will be held in Detroit, Mich., Aug. 28-Sept. 2.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NATIONAL FERTILIZER ASSOCIATION will hold its twenty-ninth annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 12.

NATIONAL LIME ASSOCIATION will hold its annual convention June 14-16 at the Hotel Statler, Cleveland, O.

NEW JERSEY CHEMICAL SOCIETY will meet at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

The following meeting is scheduled to be held in Rumford Hall, the Chemists' Club, New York: June 9—American Chemical Society, regular meeting.

The Railroad Wage Decision

THE wage decision announced May 29 by the Railroad Labor Board, signed by the three railroad members and the three public members of the board, states that the new wages will be higher than in other industries for similar work, a margin having been allowed to cover the hazards of employment and other considerations. The dissenting opinion, of the three labor representatives on the board, says that the wages decreed are insufficient to sustain life on the basis of American standards.

Here is a big issue and at the same time a very simple one. It cannot be claimed that the wage rates prescribed are relatively low, for the board had ample basis of fact to warrant the statement that railroad wages will be higher than other wages. The contention of the minority, then, is in essence that all wages in the United States are too low to sustain life on the basis of "American standards."

Now the use for wages is to spend them for commodities and services. The commodities and services must be available or they cannot be bought. Imagine a small island inhabited by a single native possessed of a certain amount of food. Two men are shipwrecked on the island, each with $1,000 in his pocket, and the native is quite willing to sell all the food he has. Each of the shipwrecked men, other things being equal, will get half. If before they started to bargain you had given each man $1,000 more money they would not have got any more food. There would simply be $4,000 passed over instead of $2,000. The food would not be Americanized by that means.

Estimates of the national income of the United States made respectively by counting up individual incomes and by counting up the value of the production substantially agree. The income buys what is offered for sale. If we want more we must produce more. We cannot increase the quantity of material and the amount of service by bidding more dollars.

To carry on industry at all in these days the workers must have tools and direction. The railroad workers could accomplish nothing without cars, locomotives and track, or without managers to direct their work. These things, tools and management, have to be paid for. Approximately speaking, between 20 and 30 per cent of the total national income goes for these purposes, workers for wages and salaries getting the other 70 or 80 per cent. And there is strong reason for holding that the workers are better off when the share for tools and management is 30 per cent than when it is 20 per cent.

There is, then, only one way to bring about a higher standard of living generally, and that is to increase production, by men working harder and more efficiently and with better tools.

Artificial Industrial Conditions In Europe and Germany

HISTORY portrays LOUIS XV as a conspicuous example of the indifference of a monarch to the welfare of the masses and the consequences of his own extravagance. When his advisers remonstrated with him, he is reported to have said, "After me the deluge." The expression typifies the attitude of the then ruling class.

Something of the same spirit is to be observed today among industrial leaders in Europe. In Belgium and France a few powerful leaders and their entourage feed the people with the doctrine that everything will be all right when Germany pays the reparations, but in the meantime the people are burdened with taxes and privations. In Italy speculators in depreciated money exploit the means of production to their own profit. In Switzerland another group buys at depreciated foreign value and sells at home at Swiss currency value with resulting profit to themselves and damage to Swiss production. In Germany industrial and economic conditions are critical to the breaking point. Russia has already disintegrated under the baneful influence of a small but dominant group of leaders. In fact, throughout Europe one can observe artificial industrial and economic conditions created by small groups of leaders whose opinion is dominant for the moment, but whose thinking is unsound. Not only are these things largely responsible for the industrial situation in Europe, but the repercussion of bad business resulting from unsound economics is felt in the United States and affects our own business revival.

In Germany particularly we may observe a curious combination of conditions. Production is at full capacity. There is no unemployment, and yet wages are abnormally low. The bulk of production is exported at prices comparatively lower than for home consumption; but the revenue, instead of finding its way into Germany to ameliorate local conditions, purchase raw materials and repair the wrongs of the war, is invested outside the country as personal insurance of the industrialists against the inevitable ruin that must overtake the unsound business policy at home. It seems inconceivable that industrial leaders can thus selfishly hasten the bankruptcy of their country, but such apparently is the case. After them the deluge!

In order to justify this treatment of the laborer, whereby he gets but a small fraction of the value of his labor, he is fed with the doctrine that exportation is necessary in order to meet the reparations, and that the price must be low in order to meet competition. At the same time the doctrine of hatred for the Allies is being instilled into the worker so that he will the more readily accept the unfair treatment to which he is subjected. The picture is not a happy one, revealing as it does the domination of the country by a compar-

atively small handfuls of industrialists who exploit the people to their own advantage. This domination, we learn, extends also to the press and even affects scientific research, but that is another story. The sad fact is the present domination of one class over a mass of 70,000,000 people.

Another curious phase of the situation seems to be a fear, certainly an unwillingness, on the part of the intellectuals of the country to expose this uneconomic and unfair industrial policy and bring to bear through some medium or other the pressure of opinion that would immediately modify existing conditions. Engineers, scientists, technologists, economists and other trained thinkers in Germany recognize the folly of the present artificial industrial situation, and yet they are evidently without courage to express their opinion or exert their influence. In this country they would have the benefit and co-operation of an independent technical and business press through which to voice their protests.

This leads us to say to the technical press of Germany that it has an unprecedented opportunity for service to its country and the technical industries which have flourished there so highly. If the technical press itself is not also under the domination of German industrial leaders, let it adopt a vigorous editorial policy that will expose the futility of the present industrial system and the disaster to which it must inevitably lead. Let the German intellectuals, whose own independence is threatened by industrial domination, and whose welfare is directly affected by the present situation, express their honest opinions regarding the exportation of German production and the exploitation of the workers by a few leaders who are profiting at the expense of their own national prosperity. If a beginning of this kind could be made, we believe it would grow in volume and influence until it would become a strong factor in rectifying the present uneconomic condition.

A Research and Educational Plan For the Packing Industry

FRANK analysis of the present trend of development in the packing industry, keen appreciation of work being done in other industries to advance the science of efficient and economical production and a sincere desire to have the largest industry in the country keep step with such progressive movements characterize the development plan for the Institute of American Meat Packers prepared by the president, THOMAS E. WILSON. By recent action of the executive committee, the plan has been transmitted to the entire membership for consideration at the next convention.

Since its establishment in 1919 by reorganization of the American Meat Packers' Association, much of the Institute's work has been directed toward the establishment of more cordial relations with the livestock producers on one hand and the retailers and the public on the other. These efforts, as well as others within the industry itself, have been attended with such a measure of success that Mr. WILSON sensed the opportunity for laying out a definite plan of enlarged activity and broader service, to guide and stimulate future growth.

Critical analysis of the methods by which the industry is progressing at present discloses several ways in which the Institute could function for the benefit of the whole industry. Attention was directed particularly to such points in the present system as: Unnecessary duplication of research and development work; the lack of an adequate system for perpetuating and handing down to the next generation in readily available form the results of past experience; lack of organized instruction of employees; no opportunity for executives in one branch of the business to broaden their perspective; no educational feeder of men whose training fits them especially for this industry.

With these points in mind, Mr. WILSON has outlined a plan for the Institute, details of which appear in our news pages of this issue. It contemplates an ambitious program and one which will require detailed study to determine the best method for carrying out each recommendation. For this purpose, Mr. WILSON proposed an Institute plan commission, which has been appointed by the executive committee with instructions to begin functioning at once. In this way no time will have been lost should the proposals of the commission be approved by the convention. This action indicates the presence of a genuine spirit of progressive co-operation in the packing industry, and it is to be hoped that the plan will materialize. It will be a great step forward.

Big Business And the Technical Man

ANOTHER billion dollar merger! Independent steel companies to form a trust which will rival the U. S. Steel Corporation!

So say the newspapers. Adjectives such as immense, colossal, gigantic come to mind. If you have ridden by the properties along the shore of Lake Michigan—a part only of the prodigious scheme—the physical magnitude of the project will begin to dawn on you.

What does such a project do to the technical men in the organization concerned? What of their work, their prospects, their future? A very pertinent comment of STEPHEN LEACOCK may find happy application here. Said he in substance: "A man who has a million dollars may be a good fellow, enjoy golf, play a good game of bridge and tell a good story. A man with five million dollars may still be able to speak graciously to his employees and colleagues, but a man with twenty million is just twenty million." There is something very similar about corporations. A small corporation may be imbued with the kindly spirit of a splendid man. A larger corporation may feel the personality of someone, but to a lesser extent. The larger the corporation becomes the more like a ruthless, inexorable machine it seems. The individual becomes a cog. Whole groups of individuals are lost to view. The great machine grinds on.

Technical men do not suffer as does the untrained man, but it reduces business relationships to its lowest terms. Big business cannot easily ask for loyalty when it reserves the right to eliminate a man or groups of men for mere expediency and not because of individual lack of worth or lack of effort. The problem is large and is ours as well as that of boards of directors. It must be solved by compromise. Loyalty and enthusiasm we give for fair treatment and security. Can big business pay the price? Can billions become human?

The answer is not going to be found in welfare committees, but in a genuine effort in business to regard the individual as a person with ideals and aspirations, with needs and desires and not as a cog—a unit quantity of energy purchased like so much lemon juice while the rind is cast out with the refuse.

Is the Steel Corporation On the Decline?

A MONTH or more ago the United States Steel Corporation held its annual meeting and its twentieth yearly report was presented to stockholders. Judge GARY made, as usual, a felicitous address and any stockholder present had the opportunity to say what he pleased or to ask questions. The meeting proceeded in amity and the chairman of the board, the finance committee, the executives and the directors were justly thanked by the stockholders for their able services and competent administration of the corporation's affairs.

Judge GARY said among other things: "The corporation has made steady, intelligent progress from the time it started. We have fortified our positions, we have become stronger, we have added to our capacity and our wealth. . . . We expect to meet competition, sharp competition. We have no feeling of hostility toward competitors or anyone else. We are going to do our duty as we see it. . . . We are subject to criticism . . . and sometimes it will be unfair. That has no influence upon us except, when we hear or read a criticism which we think is deserved, we try to improve our methods accordingly."

We agree with the stockholders present in believing that the corporation is to be congratulated on its excellent leadership and its frank reports of its conditions—with one reservation. Its leadership is immensely able so far as it leads and its reports are full so far as its property, sales and cash accounts are concerned. The criticism that we make is presented in all good will and from the standpoint of a stockholder of long standing.

Here is the greatest corporation in the world. Its leading occupation is within the field of metallurgy. It produces and sells mainly iron and steel, although its vast dominion includes the production and sale of cement and the operation of gas wells, railways, steamships and a great variety of subsidiary activities. Now in all the report and in the remarks of the chairman and in the comments of the stockholders themselves it would seem as though not only the theory of steel making but the technology itself were but minor features, whereas the number and size of the blast furnaces, the list of mines, quarries, railroads, steamships and above all things of sales, were the features of leading interest. We fail to find any reference to the quality of its products. The statistics have to do principally with tonnage. Of course, it may be said that big tonnage proves quality to be satisfactory, but the blind spot may be found in that very statement! How do we know that the quality of today will be satisfactory tomorrow? Or that the costs of today may not be lowered by research by next year, and with no reference to wages or coal or transportation costs?

In other words, the very heart of the business passes without comment. Steel is the subject of constant research, and improvements in product and in processes are constantly reported by the corporation's competitors. We are familiar with the fact that many of the Steel Corporation's subsidiaries maintain well-equipped research staffs, but whatever they find out is apparently held for internal consumption only, or is directed solely to the solution of operating difficulties appearing under their own special conditions. If any fundamental researches on iron, steel or its alloys is being done, nothing is being said about it. As a matter of fact, we men of today know that to talk of secret research and practice of metallurgy is a delusion.

We do not find on the board of directors or among the leading administrators of the Steel Corporation, as published, a single man of scientific training or of whom it is reasonable to expect that he has the scientific vision. It appears to be operated by the Old American Method under which finance and legal acumen control, while Science punches the time clock and is hired and fired according to the pleasure of the finance committee. We may be wrong in this view, but the report gives the impression. The New American Method is that practiced by the General Electric Company, the Westinghouse Company, the American Telephone & Telegraph Company and a number of other organizations that keep constantly in the forevan of scientific knowledge and understanding because they practice research, welcome theory, resolve it into practice—and then are not ashamed to tell the tale.

With all good will we wish the Steel Corporation would indicate an interest in the scientific side of its great business and change over to the New American Method of administration. It would be a grand thing for this country if it did. We believe it would be following a course of self-preservation as well, for undoubtedly the metallurgical progress of tomorrow is not to come through bigger business or bigger blast furnaces and rolling mills, but through the precise application of science for the production of quality metal.

Judging Coal Prices

HOOVER, with customary courage and vigor, promises to fix on his own personal responsibility a set of fair prices for coal. So long as the present labor disturbance in that industry creates an emergency, he will ask those producers who are able to operate to accept as a fair price no more than the charges which he will name after careful consideration of all factors in the situation. This is a public service of first magnitude. The Secretary quite properly says in this case that a man who is not willing to accept on behalf of the public the burden of large responsibility in time of emergency is not competent for public office. Judged by this measure, and for any other so far as we can observe, no one can gainsay Mr. HOOVER'S full competency as Secretary of Commerce.

But there is another side to the question and another responsibility in the matter which rests upon coal purchasers. Those in the chemical industry who find themselves with unfortunately low coal stock should do their best to avoid competitive bidding in limited markets. It may be that the need for coal will quite justify on a dollar-and-cent basis the payment of exorbitant prices temporarily. But wherever possible the purchaser should avoid any such payments as will tend to undermine the work of the Secretary in fixing fair base prices for bituminous coal.

Whenever it may become necessary to pay a bonus or excess above a "fair price," it is to be hoped that the purchaser will do it under protest. And this protest should not be the only result. Mental note should be made of those producers or dealers who use the emergency situation as an opportunity for large profit. If industry once makes coal profiteering unprofitable, it will promptly disappear. Now is a golden opportunity to accomplish this. A moral standard of action has been set up. The coal user will have full basis for judgment. Let him exercise it.

Readers' Views and Comments

Shipping in Bulk

To the Editor of Chemical & Metallurgical Engineering

SIR:—Your editorial on containers for coconut oil in the April 12 issue is of interest, but I suggest that the objection against the use of oil tankers for this purpose is not an insuperable one. After an experience in coconut plantations and on ships carrying copra in the tropics, I can bear witness to the deteriorated condition in which the dried coconut reaches the oil-expressing plant after a long journey. This we found was due largely to the propagation of what are known as copra bugs—small black beetles; these multiply with amazing rapidity in the humid atmosphere and help to flavor the sickening stench that emanates from the hold of a ship carrying copra in the tropics. It is one of the mysteries of chemistry that an edible and odorless product can be produced from such material, but experience has proved that it can be done with remarkable success.

My point is that if odorless preparations can be made from copra in such a condition, surely it is possible to cleanse tankers so that the degree of contamination of the vegetal oil with petroleum on the return trip would be negligible. The holds of such tankers are, I believe, fitted with steam coils, by which it should be possible to facilitate cleansing. The cost of the operation, in proportion to the enormous saving in freightage and transference, would be insignificant. Much deterioration would be avoided.

One of the heaviest costs in shipping nitrate from Chile is for the jute sacks, which come from India. The nitrate is sacked at the oficina and taken on flat cars to the port. Here it may lie in a warehouse until the individual sacks need be pried apart. Damage also occurs when loading into the lighter, during transference from the lighter to the slings and from the slings to the ship's hold. In many cases the number of intact sacks that have survived the jars and jolts of travel and have escaped being torn apart by the ugly hooks used by the Chilean stevedores is only enough to form four walls to inclose a pile of torn jute and loose nitrate in the center of the hold. Much resacking is done on the lighter and more at the port of arrival, all of which tends to increase greatly the ultimate market price.

It has been maintained that Chilean nitrate cannot be shipped in bulk, on account of its cementing properties. However, it would appear that, if clean and dry, there is no danger of such action. From my experience with this product in Chile I can see no reason why these two conditions could not be obtained at small expense.

To date, in spite of the magnitude of the natural nitrate industry, little attention has been paid to the question of the special freighting of the product. The present methods are not only expensive but unnecessarily wasteful. As soon as Chilean nitrate meets with serious competition with a synthetic product manufactured in the United States it is probable that economies in transportation methods will be adopted that will reduce appreciably the cost of fertilizer to the consumer.

San Francisco, Cal. A. W. ALLEN.

Rapid Determination of Tungsten

To the Editor of Chemical & Metallurgical Engineering

SIR:—The following method for the determination of tungsten should be of interest to chemists who must make preliminary tests on electric furnace heats. For such work time is valuable. With good facilities a tungsten determination by this method can be completed in 35 minutes, and the results are absolutely dependable. It is not applicable for steels containing large amounts of chromium or for high-speed steels, but the writer has been using it very successfully for more than a year on steels containing up to 1.50 per cent carbon and up to 1.50 per cent tungsten. Proceed as follows:

Dissolve 5 grains of drillings in an 8-in. evaporating dish with 90 c.c. of 1:2 nitric acid. After violent action is over, place over a high flame of an Argand burner and boil until action ceases. Add 20 c.c. of potassium permanganate solution (30 grams per liter) and boil for several minutes; add sodium nitrite solution (25 grams per liter) until the manganese dioxide has all been reduced.

At this stage the solution in the dish should be a clear amber color, as all the tungsten will be in solution. If any scale has been weighed up with the steel, it can be seen readily and should be removed, as it will not dissolve later. However, it is better to make sure that the sample contains no oxide, as the result will be vitiated accordingly.

Add a small spoonful of paper pulp and 30 c.c. concentrated hydrochloric acid and continue boiling; then add 100 c.c. of boiling water, next 15 c.c. of cinchonine solution (75 grams per liter of 1:1 HCl) and continue the boiling for 5 minutes. Filter through a 15-cm. Swedish filter No. 0, using suction. Wash thoroughly with a wash made as follows: 900 c.c. water, 35 c.c. concentrated HCl and 15 c.c. cinchonine solution. Use this wash hot. Burn in a weighed platinum crucible and weigh.

The difference in weight calculated in the usual way gives the tungsten, which will be free from silica, and if the operator has been careful it will also be free enough from iron for general technical purposes.

Bridgeville, Pa. FRANK G. ROHM.

The Ignorant Forge Shackles for Progress

To the Editor of Chemical & Metallurgical Engineering

SIR:—Right you are, Brother Parmelee! Whether or not you were directly responsible for the editorial headed "The Ignorant Forge Shackles for Progress," I wish to commend your courage and judgment in printing it.

One of the editors of a Maine newspaper (not our own local) assured me the other day that we need expect no trouble from Bryanism, for the very simple and obvious reason that no thinking man would listen to Bryan; conversely, he (Bryan) and others like him need expect to number among their disciples *only* the unthinking. What a comforting thought for those of us who like to feel that we do, occasionally, think!

At a conference of ministers which I had the pleas-

ure of attending in a lay capacity not long ago, one of the members insistently called attention to this menace to intellectual freedom. The assembly, representing what is usually considered the most liberal and progressive of all the denominations, listened more or less patiently to what he had to say—and turned to other matters of greater importance.

Are we asleep? Do we not realize that the docile sheep are in vast majority; and that once they have been stampeded the independent goats (pardon the implication) may butt and kick and dance and bleat to the limit, and will succeed in nothing but in making a spectacle of themselves?

Do we imagine that the days of Quaker persecution and of the hanging and burning of witches are so far away that they can never come back? Those things happened yesterday, and may happen again tomorrow. My wife's maternal ancestor, Cassandra Southwick, not so very many generations back was cruelly whipped at the cart-tail for refusing to give up her spiritual and intellectual independence at the behest of the fanatics of Salem. It is not pleasant to think that our great-grandchildren may, some time, suffer a like humiliation. Is the picture overdrawn? It is not.

It is for the few—among whom we like to count ourselves—who know how to place a true value upon freedom of thought, to throw off their coats, roll up their shirt-sleeves, and pitch in. *Otium cum dignitate* has been the motto of the scientific thinker too long: let's keep what "dignitate" we may, but throw "otium" into the discard.

FREEMAN F. BURR,
Acting State Geologist.

Augusta, Me.

Italian Chemical Industries

FROM OUR SPECIAL CORRESPONDENT

GENOA, ITALY, May 2, 1922.

IT IS altogether appropriate that the Italian chemical industries behaved somewhat like a turtle during April. The Italian lira was undergoing very severe oscillations in value and consequently the foreign values of the lira fell. Many reasons lie behind this variation, the overcrowding of ports with retarded deliveries of coal and raw material, the general excitement created by the International Conference at Genoa and many others.

TRADE ASSOCIATION IN THE ALCOHOL INDUSTRY

A large and comprehensive trade association was organized recently at Brescia for protecting the interests of the distillers of alcohol from grape residues. It is expected that this organization will be able to effect considerable improvement in conditions.

SULPHUR MARKET SLOW

It is quite natural that the sulphur industry should continue at a low ebb owing to the lower quotations of the lira in America and to special local conditions in addition. Several new firms, however, were incorporated for the exploitation of new or neglected sulphur mines in Sicily, one of them with a capital of 100,000 lire. The production in 1921 of brimstone reached 284,000 tons, that of ground sulphur 28,000 tons and of iron barytes 448,000 tons. This represents about one-half of the pre-war figure. A corporation created for assisting the sales of sulphur was able only to dispose of 105,000 tons during 1921, of which 42 per cent was destined to continental Italy. In order to assist the industry, the government has reduced taxes and arbitrated the wages of workers in sulphur fields and also taken action with regard to disputes between agriculturists and other land owners and the sulphur mines. Railway tariff is also under revision.

SULPHATE OF SODA EXTRACTION

Mines near Bompensiere in Sicily are ready to be worked for sulphate of soda. Mineral deposits in these mines consist principally of glauberite (sulphate of lime intermixed with sulphate of soda). Warm water is used to extract the sulphate of soda in the mine shaft and the concentrated solutions are then pumped to the surface and crystallized out. A similar principle of extraction is used in Austria. It is thus possible to use material much poorer in sulphate of soda contents than would ordinarily pay to extract.

ACIDS AND FERTILIZERS

During the past year a great deal of profit was made by Italian fertilizer work and several new firms have been created in spite of the effort of the Montecatini Works, which is trying to absorb all of the Italian production. A new fertilizer has come into prominence, consisting largely of mineral sulphate with concentrated sulphuric acid and a small quantity of cyanamide. Sales of fertilizers, very light early in the spring, have increased now and have already passed the sales of the corresponding period last year. A new process has been developed by the Prodotti & Concimi Chemical Co. for using the waste vapors from the Gill stoves in making sulphuric acid. These until now have been entirely lost and a considerable reduction in the market price of sulphuric acid is to be hoped for as a result of this interesting experimental work.

MINERAL PRODUCTION

Below are listed a number of products used in chemical industries, and the figures which follow them refer to the tons produced in 1921:

Magnesium sulphate, 350; barytes, 13,500; china clay, 13,500; carbonate of lime powder, 6,500; asbestos, 420; graphite, 7,750; boric acid, 2,500; alunite, 1,170; mercury, 1,070; rock salt, 45,400; gold minerals, 80; silver minerals, 9,000; copper minerals, 22,700; lead minerals, 26,500; iron minerals, 274,000; manganese minerals, 4,700; zinc minerals, 69,000.

Recent cable dispatches indicate that business conditions in Italy are improving. The number of business failures is considerably less in April than it was in March, and unemployment is also encouragingly decreased. Government expenditures during the last half of 1921, as recently announced, represent a cut of 25 per cent over the same period in 1920. All of these things indicate a healthy and recuperating condition.

Artificial Silk Manufacture in Italy

There are five mills in Italy, all in the northern section, manufacturing artificial silk. Their total production is about 8,000 kg. (17,637 lb.). One of these factories, situated in Venetia, employs about 1,000 laborers, of whom 800 are women, and produces about 2,000 kg. of artificial silk. This concern is erecting two new mills, one at Naples, the other at Rome, which are expected to be completed in 1923. Most of the artificial silk manufactured in Italy is uncolored. The Italian industry now exports considerable amounts of artificial silk in addition to supplying the domestic demand. In 1921 the total exports amounted to 588,834 kg., of which 173,876 was sent to the United States.

Regional Meeting of Steel Treaters in Pittsburgh

Standardization of Tool Steel Opposed by Dr. Mathews—Fiber in Steel, as Revealed by Macro-Etching, Essential for Tough Metal—A Machine for Measuring Abrasive Resistance Described —Heat-Treatment of Armor Plate and Impact Testing Also Discussed

THREE months ago local organizations of Steel Treaters near by New York met with their national officers in the first regional meeting. Last week (May 25 and 26) Pittsburgh entertained similarly. And a very successful meeting it was; somewhat more pretentious than its predecessor, it carried technical sessions over two days, and included a rapid excursion through the Edgar Thompson plant of the Carnegie Steel Co. and the extensive Westinghouse works at East Pittsburgh.

Friday evening a banquet was served to about 200 members at the University Club. Dr. John A. Mathews, president of the Crucible Steel Co., was the principal speaker, and as usual drew upon his rich experience and knowledge of the manufacture and properties of fine steels to present some wholesome advice to the younger men.

Recalling that in his brief life he had witnessed, or had participated in, almost every new application of science to the testing and heat-treatment of tool steels, he predicted that the advances of the last 20 years would be surpassed in the next decade. Therefore it was necessary for the ambitious men to keep their minds open to general science, read widely, and build up a mental card index of references to practices in allied industries and sciences. Such references can often be put to use by their owner in the most surprising manner.

Furthermore, he warned against shackling progress by too much standardization. A standard is useful in many ways, but it is tacitly assumed to be the best, not only the best that has come before, but the best that will come after. Once a standard is fixed, every effort is made to suppress variations; yet only through the study of variations can progress be made! While he had every reason to sympathize and co-operate with a progressive works which had fixed upon a certain kind of tool steel for a certain operation, and was determined that those tools be made as nearly alike as possible of exactly the same material, he was opposed to any body of men insisting that the same steel and the same tool should be used for all shops doing that kind of work. Even tool steels were not well enough known to permit such rules being followed, although tool steels had been made since steel was invented, and many manufacturing operations had been agreed upon as best practice long before science had for good reasons approved those same operations.

Fiber in Steel

Prof. F. F. McIntosh of Carnegie Institute of Technology gave an address before the technical session on "Fiber in Steel and Iron." His lecture noted that metallurgists seldom considered fiber of importance. It was therefore a little-studied subject—in fact so little was known about it that there was no precise and accepted nomenclature which could be used to describe the known facts. Yet it would often be impossible to produce tough forgings of intricate shape without careful attention to fiber.

Fiber was often studied with the aid of deep etching reagents, suitable for revealing macrostructure. If such etching developed in a forged piece a well-defined, parallel structure similar to a bundle of very fine wires, which "wires" suffered no abrupt change in directions or foldings back upon themselves, then the piece under overpowering load would be expected to tear apart slowly and exhibit a fibrous fracture, and it was said to possess "fiber." If these conditions were not met, fractures would favor the folds in the macrostructure, often under low loads, they would occur almost instantaneously, as in brittle material, and the fracture would be crystalline. Prof. McIntosh exhibited a series of macro-etchings to support his contention that this fiber could be traced back through all the manufacturing processes into a characteristic dendritic structure in the ingot. It appeared to be absolutely independent of the chemical analysis, as ordinarily performed, and seemed to originate in the way the steel was deoxidized and the conditions during ingot cooling. How the steel making conditions affect dendritic structure is not known with sufficient precision to warrant generalizations, but since selective freezing of iron from melts containing substances of varying solubility is responsible for the cored dendritic structure revealed by deep etching, the same foreign substances—substances which are not iron, even though perfectly normal constituents of commercial steel—are in some way responsible for the production of fiber in the finished piece.

It is important, as E. J. Janitzky, of the Illinois Steel Co., pointed out, to note a line of demarcation between the amount and kind of interdendritic segregates responsible for fiber—if such be accepted as the cause—and that amount or kind which is thought to be responsible for "woody" fractures, so called. Woody fractures are fibrous to the extreme, they occur in steels having extremely low transverse ductility, and are to be avoided altogether. He called attention to a German war specification demanding fibrous structure for crankshafts. It has been contended that an electric furnace which first works up an oxidizing slag, then follows it with a reducing slag, will produce metal with fiber, whereas one which makes up two reducing slags only will produce steels markedly deficient in this elusive property.

W. B. Crowe, of the Carnegie Steel Co., agreed that fiber, laid in a proper direction, was an essential to steel which must pass a ballistic test. He confessed that he was much mystified by the subject, even after many years' study. Two armor plates of the same chemical composition, manufacture and heat-treatment—at least as near as may be in practice—might differ markedly in fiber, even though the one lacking fiber might have superior tensile strength and 65 per cent reduction in area. Furthermore, size of specimen would have much

to do with it. One steel might exhibit fiber in specimens as large as it was possible to break under a press, yet another exhibit fiber only in relatively small pieces. Certainly foreign matter (often called sonims) has much to do with the problem.

Armor plates which fail under the ballistic tests will often be found to contain dirt accumulated along definite, continuous laminations, or on the other hand may be found to be very clean steel. Best results seem to be had when the sonims are uniformly distributed in tiny particles with no continuity of arrangement.

Heat-Treatment of Large Masses of Steel

Continuing on the peculiarities shown in the way large blocks of metal respond to heat-treatment, Mr. Crowe said that the chemical composition had a great deal to do with it. For instance, chromium-vanadium, nickel-chromium and nickel-chromium-molybdenum steels containing 0.45 per cent C in big slabs, 12 in. thick, might be quenched in water from a correct temperature, would exhibit a fine porcelanic fracture for a depth of 3 to 4 in., with the interior semi-porcelanic, and be unmachinable throughout. If these same steels were air-cooled from above Ac_3, they were still unmachinable, and when drawn to give 20 per cent elongation would have quite superior physical properties. On the other hand, similar slabs of a 0.55 plain carbon steel and a 0.40 C chromium-molybdenum steel, when water-quenched from temperatures which in 1-in. test-bars would give the same results as 1-in. test-bars from the other alloys, gave a fine granular fracture at the surface, gradually coarsening to a medium fine grain at the center, and were machinable throughout. In particular, the 0.40 C chromium-molybdenum steel, quenched as a 1-in. bar from 820 deg. C., gave Brinell hardness corresponding to a strength of 300.000 to 325,000 lb. per sq.in. A similar bar cut from a quenched slab gave 140,000 lb. per sq.in. at the surface and 130,000 lb. per sq.in. at the center. If the slab were quenched from 875 deg. C. or 1,050 deg. C., there was no distinguishable difference in fracture, and the uniformity in strength surface to center (as indicated by the Brinell machine) was remarkably constant.

These notes were given as specific instances that laboratory experiments were a poor guide when selecting the temperatures for heat-treatment of large masses. Usually the metallurgist had the opportunity of using one steel which would give the required physical properites after a simple drastic treatment, or another which would require a complex, mild treatment. In general, the former is preferable, if it will produce a high percentage of acceptances, and leaves the unacceptable pieces sound and in shape for a re-treatment. On the other hand, if many pieces are ruined, it would be well to go over to the complex treatment. In any case, uniformity in practice should be the aim.

Quenching by water sprays may be hazardous from many causes, and may be superseded by a different steel quenched in oil, air, or hot water. Laminations and welded blowholes appear to be particularly active causes of quenching cracks; they seem to prevent the uniform conduction of heat through the steel. Sometimes such materials can be handled by quenching to just below color.

It is especially necessary to heat cold slabs very carefully and slowly up to 350 deg. C. in order that they may pass through the brittle range without spontaneous fracture. Complete saturation at high temperatures is quite essential; a good rule for slabs is to allow 1 hour per inch of thickness to heat, and then 40 minutes per inch to soak. Bars take only half this, cubes and balls one-third. This lag in heat, surface to center, is especially vexatious in quenching operations. Often it may be taken care of by quenching from a considerable temperature above the critical; then the lag occurs before the transformation range is reached, and it is then crossed at sufficient speed to produce the hardening effect. This practice may coarsen the grain size, and require an extremely long refining heat just above Ac_3. Recrystallization may be speeded up by reheating 100 to 125 deg. C. higher. If this grain is still too large, the next refining may be 50 deg. C. lower; the crystal grain is thus "stepped down." Ordinarily the piece should be quenched only after the last heat.

Impact Testing

J. M. Lessels, of the Westinghouse company's research staff, read a paper on impact tests, in which he remarked that their laboratory was making satisfactory use of the Izod machine. It appeared to be quite sensitive to changes in quality in the metal, and in hardened alloy steels seemed to vary as some function of the reduction of area. He was careful to emphasize that the Izod test was a measure of notch brittleness, and should not be used to measure the endurance under repeated and alternating stresses.

Much discussion was forthcoming on this paper, mostly from those who were uncertain as to just how to interpret impact tests. Some speakers objected to testing steel in a notched condition, when designers carefully avoid notching their material. Others alluded to the difficulty in getting notches precisely alike, and in eliminating other sources of instrumental error. Attention was called to recent work on Sulphur in Rivet Steel[1] which demonstrated that Charpy and Izod tests would not give consistent results on very uniform steel, and these notched bar tests were totally at variance with impact shear on unnotched specimens. The Stanton repeated impact test was recommended by R. J. Allen, of the Rolls-Royce Co., and was described as a method which in his experience had been successful in picking out steels which in severe service actually gave superior results.

Abrasion Resistance

Preliminary results obtained from a machine designed for the R. D. Nutall Co. to measure abrasion resistance of gear steel was presented by A. M. Cox. It consists of a pair of motor-driven manganese steel rollers 3 in. diameter and 1 in. face set with a little clearance, one geared to run at 300 and the other at 330 r.p.m. In the crotch between these rollers is placed a test roller, 1 in. diameter, which in turn is pressed down by a weighted idler. The effect of the combined rolling and slipping abrasion is noted by weighing the test-piece after a counted number of revolutions. In general, the loss in weight during short runs on a roller varies directly with the number of revolutions. Furthermore, the most abrasive-resisting steel appears to have a medium hardness, although runs on different samples, in what are thought to be identical condition, do not check one another as well as might be desired. A first result of these tests has been the selection of a particular type of steel for gears to follow manganese steel pinions, a selection which has turned out to give extremely good results in heavy machinery.

[1] Reviewed last week in Chem. & Met., p. 1019.

The Business Side of Chemical Manufacturing

Article Four of This Series—The Study of Marketing Completed With a Study of the Following Departments: Sales Research, Credit, Traffic, Collection, Sales Service — A Discussion of the Theory and Practice of Those Departments

By CHARLES WADSWORTH, 3d.

MARKETING is not finished with Advertising and Sales. There are five other functions which deserve at least a brief consideration. If you will recall the diagrammatic analysis of Marketing appearing in the second article of this series, we differentiated the following functions:

1. Locate the market.....Sales research.
2. Interest it in the product.....Advertising.
3. Classify prospects .....Credit.
4. Consummate sales .....Sales.
5. Deliver the product.....Traffic.
6. Collect the bill.....Collection.
7. Keep customer satisfied.....Sales service.

The two most important units—Advertising and Sales—have already been discussed in Articles II and III of this series, and this article will complete the study of marketing by taking up the five minor departments in the order mentioned.

Before actually discussing any of the departments, it is extremely important for us to remember our general attitude on the whole subject of organization. Of necessity, we talk of these units and sub-units of organization as departments, but in many properly organized manufacturing companies they may not be departments at all. The work which such a department would undertake may actually be done for some particular company by one man who is a clerk in another department. It is, therefore, not the actual unit of organization which we are discussing, nor yet the actual creation of such a unit of organization. It may be entirely unnecessary. What is necessary and vital is that the functions which the department or sub-department carries out shall not be neglected in any organization. The company with which you are connected may have no credit department whatever, but the sales manager may have given all the thought that is necessary to the credit problem. You would find, if you examined the bills which the company sends out, stated terms, and you would also find that the company dealt with no one who was not actually known to the sales manager. Such a condition would eliminate the necessity of a credit department, but the idea behind the credit department has been entirely taken care of within that particular organization. Illustrations such as this could be multiplied ad infinitum. The point to bear in mind in all this work is this: Do not think, when credit department is discussed, or any other department for that matter, that it is necessary for your company to have a small room with "Credit Department" lettered on the door and a credit man inside. What is necessary, if your company is balanced and healthy, is that the functions of the credit department shall have been considered by somebody in the organization, and a definite policy established. This applies to all the various departments that are differentiated, and it is important only to emphasize it and reiterate it here because we are about to discuss departments which are frequently of minor or of negligible importance in chemical manufacturing businesses. No generalization of the subject is warranted or safe, except that the functions represented by each department named should have been taken care of. This much and no more!

Sales Research or Sales Engineering

Perhaps the difference between the marketing problems of the firm which manufactures for the ultimate consumer and those of the firm which manufactures for industry consumption is most apparent in this particular work of locating the market. In the case of the former, the location of the market can be undertaken by the advertising department or the advertising agency. The problem is one of consumer advertising and its solution needs no technical assistance. Expert advertising experience must be focused on the appeal to John Jones, average citizen. The market is known. The sales research problem is the study of the product and the psychology of its consumption. It is an integral part of planning the advertising campaign.

Not so with industry consumption. Sales research is not part of the advertising work. The problem may be one of two, to find uses or new uses for a product, or to develop prospects who would be interested in a product. These problems need technical training for their solution. And in fact sales engineering departments are invariably technical departments.

For administrative purposes these are usually tacked on to the sales department and the head of sales engineering will report to the sales manager. Before we go any further it is necessary to record the sad fact that this department is not widely used. This unfortunately does not mean that it could not be widely used, but rather reflects the conservatism and lack of imagination of manufacturers generally. It is at once apparent that sales engineering would vary over an almost unlimited range.

To take concrete examples of departments which are working on one of the two problems studied by this department. There is first the company which produces, for example, a metal. The sales engineering department of such a company will list possible uses of the metal as they are discovered. The metal might be used in lining equipment such as stills, pipe, valves, etc., or it might be used to make the whole still or valve. There might be a possible outlet in lining cans, in making laboratory or kitchen ware, as a wire for screens, in shingles or spouting for houses. The technical difficulties of each particular use are then studied, the limitations and advantages, the relative cost and the extent of the market. In addition, of course, trade prejudices and sales difficulties must also be evaluated.

Thus the sales research department is or should be in a position to recommend a logical market for the product.

Another company manufactures a machine for a specific purpose—a mill, perhaps, for grinding materials. The sales engineers in this company must locate new industries or firms which could advantageously use this equipment. Can their mill accomplish the results desired in that process? Is it applicable to ore or pigments or to both or to neither? A distinctly different kind of problem from the first type.

Technical Brains and Sales Problems

The point is this: In chemical industries the need of technical brains on sales problems is imperative. That is practically what sales engineering means. The sales manager may recognize this necessity, but the general average attitude is more nearly represented by the following anecdote. The story is not a single occurrence, but has been confirmed a number of times, so that it represents a composite.

The sales manager of a company was asked if it wouldn't be rather a good idea to market a given product in a different form. "Yes, undoubtedly," he replied, "but we have to sell what the manufacturing department produces." That seemed to settle it until the works manager remarked that it would be a much easier proposition to make that same product in the revised form, but he added, "You know we have to make what the sales department can sell." And there you are!

There are a great many chemical firms which might not need to create the department of sales engineering. They could handle the problem through a technical man in the organization, but there isn't a single firm that can afford to neglect the problem. Perhaps this will make some of them realize that the problem exists.

Credit

Among firms which have credit departments you will find it an unpopular department. The salesmen, who are usually the loudest talkers, are forever claiming that the credit department interferes with their work, that it is foolishly conservative and that it pays no attention to salesmen's recommendations. All of these things may be true, but it is largely a necessary and fundamental difference of point of view.

The credit department functions will vary over a limited range. It differentiates first of all between desirable and undesirable customers—those who pay promptly, those who do not and those who do not pay at all. It frequently has control over the terms of sale and can vary them with the customer. For example, a customer who is slow pay may be requested to pay cash on receipt of bill of lading. Often the department has charge of collecting bills, of which more anon.

In chemical industries the importance of the credit department will depend on the nature of the business. A firm which sells in large quantities to firms with fairly large capital will often find that a single sales clerk is all the credit department it needs. On the other hand, a firm which has thousands of customers buying often in small quantities may find that an alert, active and necessarily large credit department is essential to its very life.

The trouble in the industry has been that not enough attention has been paid to the department or to the point of view that the credit man would have. A good credit man will do more than act as curb—he will indicate desirable customers so that the sales department can turn its sales effort to best advantage.

Sources of Information

It does seem rather ironical that, after all the effort of producing and marketing, a firm has to be careful of the customers to whom it distributes. But experience, the oldest teacher in the world, has created the credit man and demonstrated his usefulness, and experience trains him in his work. There are many sources of information open to the credit man, but unless he is able to read the story behind letters, figures and opinions, many a sale will be lost through overconservatism or a large "bad debt" item will accumulate through lack of proper conservatism.

A comparatively large number of business men and even technical men are familiar with the almost miraculous compilations known as Bradstreet's and Dun's. These companies furnish an annually revised list of business houses with an easily interpreted credit rating, expressed in terms of capital and promptness in paying bills. In addition they stand ready to report on the credit rating of any firm to their subscribers.

Trade associations to which the manufacturer belongs may in some cases be able to furnish credit information about a consumer of that industry's material. The National Association of Credit Men is another source of information, while perhaps the most valuable of all, though necessarily limited, is the bank with which the firm is a depositor. Bankers are more and more coming to realize that such service is most desirable from their standpoint. Bad debts contracted by a depositor weaken one of their units. Good accounts correspondingly strengthen them. Bankers obtain this information by co-operating with correspondents in other cities.

Finally, salesmen often are extremely serviceable in obtaining opinions and forwarding their own estimates of credit reliability.

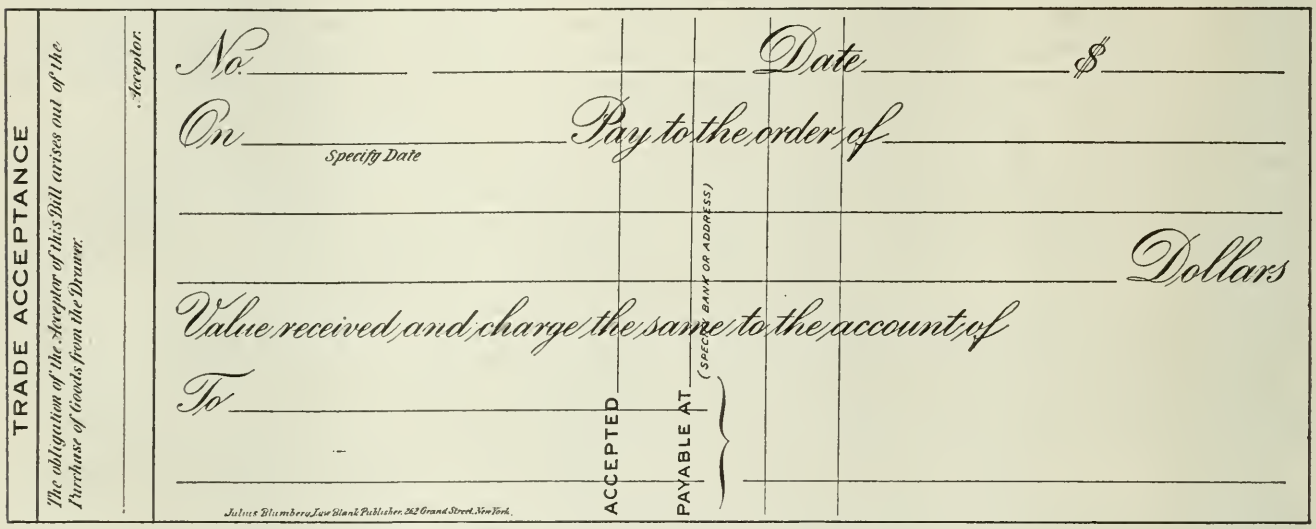
So information comes in and accumulates. As the firm (and the credit department) grows in age its own experience with customers translates itself into invaluable credit data. It should be recorded—and often isn't. A card catalog constantly revised as new data are obtained is the most convenient record for this material. Such a catalog, usually classified geographically (as Bradstreet's is also), should contain all relevant information such as capitalization, credit rating in Bradstreet's and Dun's, all other credit ratings, salesmen's estimates and finally the detailed experience of specific negotiations with the customer. Date of sale, amount of sale, terms, date account was due, date paid, history of collection follow up if necessary. Frequently elaborate data are not thought necessary, and no generalization is wise in this connection.

Terms of Sale

Fortunate is the firm, wisely financed and successfully managed, which is able to discount its bills. Under our present system American business houses run what is known as an open account with their customers. A sale of material is made and the purchasing firm is billed for the amount of the sale in accordance with certain somewhat arbitrary terms. It is nearly a universal practice to allow a discount of 1 or 2 per cent for cash within 10 days (or some definite short period of

time). To take advantage of this is to "discount a bill." The bill becomes due at its full value within 30 or 60 days and such terms are expressed as 2/10/30 or 2/10/60, which means 2 per cent off for cash within 10 days, net cash due in 30 or 60 days respectively. These terms are generally not rigidly enforced. In fact the laxity of enforcement is notorious. Cash discounts are taken without protest at 15, 20 or 30 days where 10 days is allowed. Accounts due in 30 days run on 60 and 90 days without more notice than a monthly statement. This laxity is a subtle and bad influence on general business. Nothing is more quickly demoralizing than slackness in financial matters. It is rather a mistaken idea that it is a favor to the customer to let the time dates on which bills are due slide by unnoticed. As a matter of fact, it works the other way, and a company which demands fulfillment of terms in a friendly but definite way will usually command the respect of the customer. Leaders in finance have frequently given this subject attention, and it is one of the concomitant acceptance is issued by the firm selling the goods and is "accepted" by the buyer, who then designates the bank where it will be paid. The form is then returned to the seller, who can keep it until maturity or, if he needs cash, take it to his bank and have it discounted. This means that he will receive the face value of the trade acceptance less the small discount permitted by the Federal Reserve act. Under our present system of commercial banking, when funds are necessary, a firm goes to a bank and asks for a short term loan. If the firm's standing is good and if the bank has money to spare for commercial loans and if the money market is not tight, the loan is made. Now, if trade acceptances were used, it would remove the arbitrariness of the present system.

There is another very good influence which trade acceptances would have on business in general. Under the lax collection system of open accounts a firm is very apt to overbuy. With trade acceptances, however, the fact that the money is due on a definite date and must be paid when the bank presents the note would compel



FAC-SIMILE OF A TYPICAL TRADE ACCEPTANCE

blessings of the trade acceptance system, made possible by the Federal Reserve Banks, that a higher standard of financial responsibility is certain.

The Trade Acceptance

This section is, I unblushingly confess, propaganda. Aside from the distinct financial advantage to the individual firm which uses trade acceptances, the general economic advantage to the nation is great enough to make it an almost patriotic duty to present the subject forcibly. The trade acceptance became a commercial possibility in this country when the Federal Reserve banking act was passed. This provided for minimum rate of discount on trade acceptances. In order to become eligible for this low rate of discount under the Federal Reserve act, "the bills must be the result of commercial transactions" and the proceeds must be "used for agricultural, industrial or commercial purposes." This wording was intended specifically to exclude the possibility of using the proceeds from trade acceptances in speculation.

If you will examine the fac-simile of a typical trade acceptance on the accompanying cut, you will see that it amounts to a promise to pay on a certain time, usually 60 or 90 days distant from the date of issue. The clearer and more intelligent thinking on commercial problems and a firm would not overbuy on the chance that it could let its open accounts ride along until money came in to cover them. This has proved fatal so often that it would be very desirable to supply the ounce of prevention against overbuying and other lax practices. There would be no advantage gained by offering cash discounts under the trade acceptance system, and hence the illogical cash discounts would disappear. Cash discounts at best are a very lukewarm plea for prompt payment, while trade acceptances provide a 100 per cent efficient mechanism for the same purpose. Banks are unwilling to risk loans to small firms in anything like the same proportion as they will to large firms. This, of course, is not unnatural, but it frequently works great hardship on the smaller firm. This hardship completely disappears if the trade acceptance is adopted, for a trade acceptance is as easily marketed by the small firm as by the large.

In addition to helping the individual firm, it is also of great assistance to the commercial bank. A very great many failures in commercial banking circles have been due to the fact that commercial loans were not sufficiently liquid and in times of financial stringency collections on maturing loans could not be made. This

situation would be greatly relieved by the use of the easily negotiable trade acceptance. It is, of course, perfectly obvious that when a firm asks for a loan from a bank it would ask for a fairly large amount. Trade acceptances, on the other hand, would spread this amount over a number of smaller units. In this way, the assets of the bank are very much easier to liquidate than they could possibly be under the loan system. If you multiply this by the number of banks, you will see how infinitely more flexible the credit machinery of a country becomes. Financial stringency under a trade acceptance system would be almost unbelievable.

Traffic

It is a wise plan to avoid generalizations if possible. It is wise because it is very easy to drift into a habit of loose generalization which is inaccurate and misleading. After due consideration, however, it is safe to say that the traffic work of most companies can be handled by one man in part of his time. It is also safe to say that this work is neglected by many firms to their own disadvantage. The traffic department varies somewhat in proportion to the size of the freight bills. It will thus be obvious that a heavy chemical plant is more apt to have a large traffic department than a fine chemical plant. If finally the company owns and operates its own tank car service, the traffic department becomes a major department in every sense of the word.

The department is occupied with three questions: The first one is, what is the cheapest way of routing material to its destination; the second, locating and tracing of shipments to and from the plant; and the third, the collecting of claims against the railroad or transportation companies.

The work of the department is largely routine after the system has been worked out, even in companies which have large traffic departments. In fact, the very success of the department depends on the rigid following of routine. This statement goes double in case any exporting is done. Then routine is verily canonized, and necessarily so. That subject is far too intricate for casual consideration.

Railroad Rates

There is one thing which rather impresses a man who takes up traffic somewhat seriously, and that is the work of the Interstate Commerce Commission. Our railroad rate system is rather a peculiar jumble. Before there was an Interstate Commerce Commission railroad rates were not standardized. They varied to different shippers and preferential rebates were common. Gradually some order has come out of chaos, as much order as could come from a system which has been produced by expediency. At risk of developing a point which may be familiar to many, let this serve as an illustration of what is meant. Assume a flat rate per mile of transportation, and then have clear sailing and a progressively increasing rate from New York to St. Louis, Kansas City, Denver, Salt Lake City and San Francisco. But in transporting to San Francisco the railroads encounter water competition. If they are to stay in business they must meet water transportation rates. This means a substantial diminution in the New York-San Francisco tariff. It therefore becomes cheaper to ship from New York to San Francisco by rail or boat and then reship from San Francisco perhaps even as far as Salt Lake City. In other words, the freight rate from New York to Salt Lake City may actually be more than that from New York to San Francisco plus that from San Francisco to Salt Lake City. It is at once obvious that the Interstate Commerce Commission would have a nice question to decide as to whether or not this would be equitable. This is one of the many kinds of complications which arise. The decisions of the I.C.C. have been impressive for their thorough and detailed study of difficult problems. It is easy to criticize. It would have been nearly impossible for the system to develop otherwise than it did.

Need of Discretion by Traffic Man

Naturally in a traffic department some familiarity with freight tariff and with general methods of transacting railroad business is necessary, but it is not an unmixed blessing. In one case an overpowering desire to avoid demurrage charges cost the company a good deal of money. Cars were unloaded in order to clear them from the yard and the material had in some cases to be transported to a consumption point within 3 days. A small demurrage charge would have avoided the large charge for transferring the material. So while intimate knowledge of railroad procedure is highly desirable, it should be tempered by some personal or executive restraint. All these problems which the traffic department has in hand deal with railroads principally, except as noted in case of export and except further when it is considered desirable to use motor truck transportation. Frequently a separate clerk, group or executive will have charge of the trucks and be attached to the sales department rather than to the traffic department, which seems somehow to be inseparably and often solely concerned with railroad work.

Collections

The problem which we are about to discuss has very little of vital interest to chemical-manufacturing companies. The reason for this is that most companies do not sell to the individual consumer. Their product goes to firms of relatively high financial standing, and as a general thing, no policy of collection is considered necessary.

There are inevitably bad debts, but the percentage is less than in the case of firms which market to the ultimate consumer, and are more easily avoidable. In other words, the customer who does not pay his bills is easily differentiated, and no more material is sent to him.

There is, however, a valuable point to consider in connection with this work. The normal course of collecting bills involves the sending of statements, at first merely stating the amount due, then perhaps with a "Please remit" stamped on the statement. This is followed later by a polite letter, calling the firm's attention to the fact that the bill is due, and this in turn may be followed by a rather impolite letter, threatening legal action. Finally, it may be necessary to turn the account over to a collection agency, where for a rather large commission the disagreeable task of squeezing the dollar out of the stone is undertaken. This procedure is carried out thoughtlessly and mechanically, and little consideration is given to the individual needs of the case. Not infrequently an unfortunate attitude is developed by a customer due to the rigid application of the system. Consider this from the point of view of an individual. The tactless and needless use of a large "Please remit" stamp has frequently been the cause of a change on the part of a customer. Business houses must remember

that collecting bills must be done tactfully and not mechanically. You are dealing with personal reactions even though they are masked under a firm name. This is one of the points of contact mentioned in the discussion of advertising which must be watched carefully to avoid any bad reactions from firm policy.

Sales Service or Trouble Department

The exact point at which the sales research department ceases to function and the trouble department begins is somewhat difficult to decide, but the functions are definite and distinct except on the border line. The process of locating a customer may involve and frequently does involve the confident knowledge that he will be satisfied with the product. In that sense, therefore, the sales research department is not dissimilar from sales service. Both, furthermore, are technical departments which must be operated by technical men and both represent the opinion of technical men with regard to the sales department, though, to be sure, the attention is focused on different points.

Trouble Work Should Be Under the Direction of the Sales Department

The inception of a sales service or trouble department can be rather easily described. A complaint comes in to a manufacturing concern. Some material was not satisfactory. "Why not?" asks the general manager. "Well," suggests the sales manager defensively, "the operating department really knows more about the product than I do. I suggest that they be asked to find out." This sounds logical, and the general manager therefore usually calls in an operating man, who is given this specific job of settling the complaint. In a large organization these complaints are not infrequent and therefore it may be that one of the operating men will work into trouble work. Of course it is a wrong theory for the sales department to shunt it off on the operating department. The work should be done under the direction of the sales department and in chemical firms particularly this is frequently not the case. The operating department has no sales background. It is difficult or practically impossible for the technical man to sense and reflect the policy of the sales department toward that particular customer unless co-operation is close, which it usually is not. The result is that wires frequently get crossed and wrong attitudes are developed by the customer, all of which might be avoided if the sales department were not usually so anxious to get rid of a distasteful job. This last phrase is put in advisedly and after careful thought and lengthy observation. The trouble department is so frequently not included under the jurisdiction of the sales manager and so frequently the distaste of the sales manager for this kind of work is evident that the statement represents an existing condition.

Too Few Chemical Concerns Have Trouble Departments

We have been talking about firms which actually have trouble departments and unfortunately we are talking about a relatively small percentage of chemical manufactures. Trouble departments are almost as unknown as sales research departments. There have come personally to my attention not a few firms large enough so that many complaints are received, yet without anyone to take an interest in this work. The inevitable result has been that many a customer has turned to competing firms when a little sales service work would have kept him in a friendly frame of mind and ironed out the particular technical difficulties.

There is the whole crux of the value of sales service. Technical difficulties are frequently encountered by the consuming industry and these difficulties can be overcome oftentimes by co-operation between the seller and the buyer.

Naturally the buyer, if he has experienced trouble with a product, is not likely to be enthusiastic about repeating an order. It is therefore a matter of dollars and cents to the seller to make sure that trouble does not arise from his own product and to make the buyer realize it. This logic seems to me to be the most elementary kind of reasoning and yet many sales managers in the chemical field still rely upon a kindly pat on the back and a good cigar to dispel technical troubles for their purchasers. A definite attempt is made to minimize the trouble, to make the purchaser believe that after all he really is not in trouble and if he is, that it can't be the fault of the product. Such an ostrichlike attitude can really not be tolerated in technical manufacturing and a firm is biting off its own nose if it does not see that the information which it obtains itself from trouble work is of the utmost importance in developing better products, more easily marketable and more serviceable to the industry to which it is selling.

Desirability of Technical Work

It is often not easy to point out the desirability of technical work. It has been especially difficult during the last year when firms have been cutting their technical staffs to an absolute minimum, but in the case of the sales service or trouble department, the necessity of undertaking this kind of work is becoming more and more evident, even to the rather conservative industry to which we belong. Very interesting sales service departments are to be found in most of the progressive dyestuff manufacturing companies. An effort is made to have on the sales staff of even small producers of dyestuffs men thoroughly familiar with the dyeing game. Sometimes it has been found necessary to train specialists in such things as the dyeing of paper and other special branches, but in nearly every case you will find a man in the organization who can go out and show a dyer how to use the company's dyestuffs in the plant. If only the rest of the dyestuff industry were as admirable as the sales service departments we should have nothing but praise for them. Heavy chemical manufacturers specifically can take a valuable lesson by studying this particular work. Heavy chemical manufacturers have been notoriously slow to believe that anything like trouble work is essential or desirable and, in fact, there are hardly any manufacturers of this class who make a practice of finding out whether their products fulfill the requirements of the customer. True, when complaints come in, they are frequently taken care of, but there is no systematic effort to find out whether the technical man in the consuming company is satisfied or not. Until this state of efficiency is reached the sales department may be said to be standing on relatively unsubstantial ground.

Note:—This is the last of the series of articles on the Marketing Function. In subsequent issues several articles on Accounting and Cost Finding in chemical manufacturing will be published. They will complete this series on the business side of chemical manufacturing.

The Manufacture of Ammonium Nitrate

Description of Modern Operating Practice and Considerations Affecting Design and Operation of Ammonia Stills, Scrubbers, Condensers, Neutralizing Tubs, Evaporators and Crystallizing Kettles—Use of Ammonium Nitrate in Permissible Explosives

By E. M. SYMMES
Chemical Department, Hercules Powder Co.

THE use of ammonium nitrate in explosives is becoming of more and more importance every year. Approximately 20 per cent of the sum total of the commercial high explosives made in this country each year consists of ammonium nitrate. This amounts to a very substantial figure, and small economies in yields or plant costs in the manufacture of ammonium nitrate are important items when the total is considered.

At the present time there are two sources of supply of ammonium nitrate available—one the synthetic product from Norway and Germany, the other a product made by neutralizing ammonia gas derived from coke ovens with nitric acid made from Chilean saltpeter. Synthetic ammonium nitrate shows a purity of 99 per cent or better on the dry basis and usually contains about 0.10 to 0.15 per cent of moisture. It is received in large casks, usually solidified. It is treated by breaking it out of the casks and subjecting it to a coarse grinding in a swing hammer mill, followed by heating and agitation in a steam-jacketed crystallizing kettle to reduce the moisture to 0.05 per cent or less and simultaneously to wear down the crystal structure until a fine meal is obtained, suitable for direct use as an ingredient of dynamite and gelatin.

The ammonium nitrate made from ammonia gas and nitric acid is obviously a product of the following reaction:

$$NH_3 + HNO_3 = NH_4NO_3$$

which expresses the essential features, although water is present on both sides of the equation as a diluent for the sake of convenience in manufacture.

Effect of Impurities in Ammonia on Yield

Most grades of ammonia liquor from coke-oven plants contain a number of impurities, the amount depending upon the purification to which it has been subjected. The usual impurities are:

Ammonium sulphide $(NH_4)_2S$.

Tarry bodies, both soluble and insoluble, containing small amounts of pyridine and light oils.

Fixed ammonia salts, such as sulphate, sulphite, thiosulphate, thiocarbonate, chloride, thiocyanate, ferrocyanide and carbonate.

In the direct neutralization processes practically all of these compounds are retained in the neutralized liquor in some form or other. The ammonium sulphide probably reacts as follows:

$$(NH_4)_2S + 2HNO_3 = 2NH_4NO_3 + H_2S$$
$$3H_2S + 2HNO_3 = 4H_2O + 3S + 2NO$$
$$2NO + O_2 = 2NO_2$$
$$2NH_3 + H_2O + NO + NO_2 = 2NH_4NO_2$$
$$2NH_4NO_2 = 2N_2 + 4H_2O$$

showing what a far-reaching effect sulphur has upon the reaction. The losses may be calculated on the basis of the above reactions as follows:

$2HNO_3 = 126$ molecular weight
$3S = 96$ " "
$2NH_3 = 34$ " "

therefore 1 lb. sulphur represents a loss of 1.312 lb. HNO_3
and 1 lb. sulphur represents a loss of 0.3541 lb. NH_3

One hundred pounds of ammonia liquor containing about 25 per cent NH_3 is worth about $2.75. If it contains 1 per cent of sulphur, then the

HNO_3 lost = 1.312 lb. at 6c. = 7.872c.
NH_3 lost = 0.3541 lb. at 11c. = 3.895c.
Total loss per 100 lb. = 11.767c.

$$\frac{275}{11.767 \times 100} = 4.28$$ per cent reduction in value of the ammonia liquor by 1 per cent of sulphur.

The harmful effects of the above impurities are felt throughout the system. The tarry bodies collect in black clots which float on the liquor during neutralization and evaporation, decomposing and frequently igniting and burning. Free sulphur, with the cyanogen compounds, settles out during storage of the neutralized liquor, and if not removed is a source of fires if drawn into the evaporation process. The reaction is probably as follows:

$$2S + 8NH_4NO_3 = 2SO_2 + 2NO_2 + 16H_2O + 7N_2$$

and

$$S + 2NH_4NO_3 = (NH_4)_2SO_4 + 2NO$$
$$2NO + \text{air} = N_2O_3$$

Economies of Direct Neutralization

At the present time ammonia liquor can in many cases be obtained with the tar and sulphur content as low as 0.01 and 0.05 per cent respectively. Under these conditions it can be neutralized directly by weak nitric acid without trouble from the small amounts of impurities. When liquor of less purity is used, it must be subjected to distillation to hold back the impurities and drive out the pure ammonia gas from both the free and the combined ammonia.

In direct neutralization all the water of the ammonia liquor enters the neutralized solution, and it must be evaporated finally. When using the distillation process, on the contrary, all of the water is retained by a reflux condenser and only the ammonia gas passes into the nitric acid used for neutralization. Consequently, the water of the ammonia liquor does not have to be evaporated in the end. At first glance this would seem to be a substantial economy, but further reflection will show that large quantities of steam, compressed air and cooling water are required for the operation of the ammonia still, which will offset the apparent economies mentioned above. To distill a lot of ammonia liquor of 4,000 to 10,000 lb. will require about 6 hours. To neutralize the same quantity by the direct process without distillation will require from 1 hour to 2 hours.

There is thus a very considerable saving in labor, as well as in steam and air for the still. The over-all economy of the two methods is something which must be determined by local conditions at each plant.

Effect of Impurities in Nitric Acid on Yield

The nitric acid used is usually obtained from two sources—that recovered from denitration of spent acids and that made as the weak portion from nitric acid stills. This weak portion includes both the last runnings and the tower acid. As used for neutralizing ammonia liquor it has a strength of about 45 to 50 per cent. Stronger acids will permit the temperature of the neutralization process to rise high enough to cause decomposition of the ammonium nitrate.

The usual impurities in nitric acid are hydrochloric acid, sulphuric acid and nitrogen peroxide. The hydrochloric acid is derived from the salt (NaCl) contained in the Chilean saltpeter. The ammonium chloride formed from it causes no particular trouble unless present in large amounts, in which case it reduces the strength of the ammonium nitrate as an explosive. The same is true of the ammonium sulphate formed from the sulphuric acid in the nitric acid. The nitrogen peroxide reacts as follows:

$$2NO_2 + 2NH_3 + H_2O = NH_4NO_3 + NH_4NO_2$$
$$NH_4NO_2 = 2H_2O + 2N$$

from which it will be seen that one-half of both the NH_3 and the NO_2 which enter into the reaction is lost. It is therefore desirable that the nitrogen peroxide content of both kinds of the nitric acid used be as low as possible.

All the material used is weighed carefully, and yield statements are made out at the close of each month. On account of the corrosive nature of the vapors in the house the scales used require close attention. The bases are sealed in oil, and when properly constructed will remain accurate for a long period. Frequent and regular checking is necessary if beams and weights corrode. In unheated houses it is necessary to use coal oil for the oil seal, or some low-freezing, thin lubricating oil, to prevent freezing with consequent loss of accuracy.

For the sake of economy the two operations of distillation and neutralization are conducted in the same house, so that one operator can attend to both. In starting the operation the charge of ammonia liquor is drawn into a blow-case from the elevated outside storage, and weighed accurately. This blow-tank has a vent discharging either into the neutralizing tank or into acid-absorption towers to catch the ammonia gas which would otherwise be lost. The same acid-absorption towers serve to catch the ammonia gas from the vents of the large outside storage tanks. The weigh tank has a small sampling valve near the bottom, through which a sample of every weighing is taken. This sample, when composited and analyzed, serves to determine the quantity of ammonia gas charged against the operation.

Purification of Ammonia

Since in distillation it is necessary to break up the fixed ammonia salts, lime is added to the still. The proper amount may be calculated either from an analysis of the ammonia liquor or by tests applied from time to time during the operation to see if a sufficient quantity is present. On the assumption that calcium sulphide is formed by the reaction between calcium hydroxide and ammonium sulphide, as in the following reaction:

$$Ca(OH)_2 + (NH_4)_2S = CaS + 2NH_3 + 2H_2O$$

and with dry CaO = 71.4 per cent Ca, 28.6 per cent O
and with CaS = 55.6 per cent Ca, 44.4 per cent S
1 lb. CaO is equivalent to 0.5704 lb. sulphur.
1 lb. $Ca(OH)_2$ is equivalent to 0.4326 lb. sulphur.

1 lb. Sulphur is equivalent to $\frac{1}{0.5704} = 1.753$ lb. CaO.

Example:

12,000 lb. charge of ammonia liquor containing 0.5 per cent sulphur.
$12{,}000 \times 0.005 = 60$ lb. sulphur in the liquor.
$60 \times 1.75 = 105$ lb. CaO.
Allowing approximately 25 per cent excess
$105 + 25 = 130$ lb. CaO.
Assuming slaked lime contains 75 per cent CaO

$$130 \times \frac{1}{0.75} = 173 \text{ lb. slaked lime required.}$$

A check on the proper quantity of lime to use lies in the color or the residue from the still. If white, too much lime is being used, and the excess is wasted. If a light blue, conditions are about right, only a small quantity of the ferrocyanides being left unattacked. If very dark and with an odor of hydrogen sulphide, there is a deficiency of lime and the sulphur and cyanogen compounds are not completely destroyed. Hydrated lime, although commanding a higher price, often makes a saving by reducing the labor of preparation.

The ammonia gas is driven out of the liquor in the still by heating with steam coils and agitating with air, passing the gas first through a reflux condenser to remove the water and return it to the still, and then through a scrubber where it bubbles through a solution of sodium carbonate. From the scrubber the gas goes down to the bottom of a neutralizing tub in which there is at first a shallow layer of weak nitric acid, where it reacts, forming nitrate of ammonia.

Since the lime used in the still cakes on the steam

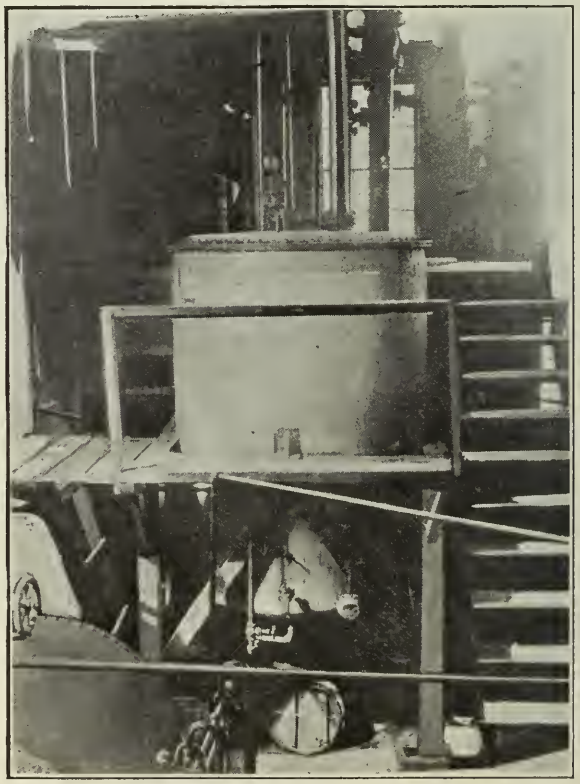


FIG. 1—AMMONIA STILL

coils, reducing the heating efficiency seriously, it is sometimes economical to substitute soda ash, which does not give this trouble.

Operation of Ammonia Stills

The still is always provided with a long manometer made of 1-in. pipe long enough to permit the still to blow out through this manometer at 10 lb. pressure, since if the discharge pipe lines were to become plugged a dangerous pressure would otherwise be built up in the still. If the latter were to burst when filled with ammonia liquor, the conditions can better be imagined than described.

The heat must be applied gradually at first, since the depth of the nitric acid originally in the neutralizing tub is slight, and a rapid evolution of ammonia gas will blow through this layer without being neutralized and will be lost up the stack. For this reason two neutralizing tubs to one still are sometimes provided.

Between temperatures in the still of 130 to 180 deg. F. there will be a so-called "prime," or very rapid evolution of the gas. As the temperature approaches this point the steam must be cut off and the rate of addition of nitric acid to the tub increased so that no ammonia gas will blow through the neutralizing tub and be lost. After the "prime" has passed the amount of air agitation in the still must be increased to carry out the remaining quantities of gas, but too much air will so dilute the gases that difficulty will be experienced in absorbtion.

Operation of Ammonia Condensers and Scrubbers

It sometimes happens that the odor of pyridine present in the still residue masks the odor of ammonia when the latter is present only in small amounts. The sense of smell should not be relied upon. The best method is to hold a strip of moistened phenolphthalein paper over the sample of hot still-residue. A slight purple tinge around the edge of the paper will indicate very small amounts of NH_3.

FIG. 2—NEUTRALIZING TUB, SHOWING FUME STACK

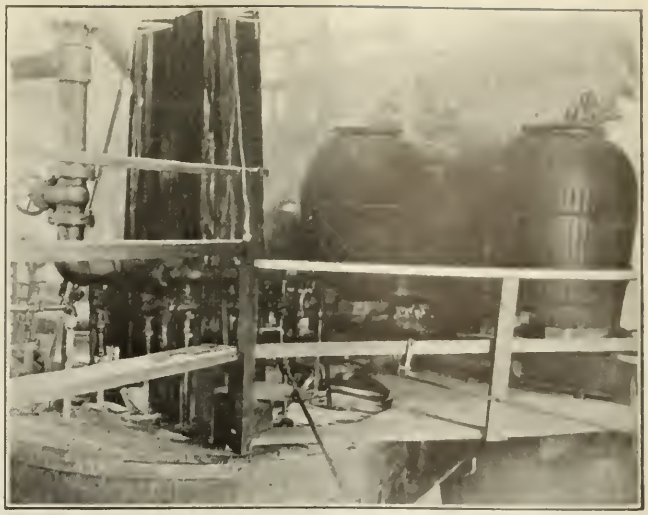

FIG. 3—TOP OF NEUTRALIZING TUB, SHOWING NITRIC ACID SCALE POTS

A condenser, properly operated, should reduce the temperature of the gases to about 120 deg. F., although this will vary somewhat with the temperature of the cooling water used. If temperatures much above this are permitted, the scrubber will fill up with condensate and require renewing.

Unless the condenser is frequently tested for leaks, losses in yields will be experienced, which are almost invariably blamed on other parts of the operation. On account of the large amount of cooling water used, the escape of ammonia gas will not be evident from examination of the water. The condensers should be tested frequently when empty by using a small water pressure.

The scrubber serves to remove any sulphur or tarry bodies which may have passed over. This, theoretically, should not happen, and the scrubber should act only as a flexible unit from which to draw a small amount of ammonia gas to finish the neutralization after all the ammonia gas has been removed from the still. As a matter of fact the scrubber does retain considerable quantities of sulphur.

The solution used in the scrubber is an 8-deg. Bé. solution of soda ash. It should not be stronger, as nothing will be gained and there will be increased opportunity for crystallizing on chilling, which will plug up the perforated distributor pipes in the bottom.

Construction of Neutralizing Tubs

Past experience has shown that hot solutions of ammonium nitrate wear out wooden tanks very rapidly either by permeating the wooden staves or by forcing the staves apart by crystallization in the cracks. To avoid this the tubs are lined with a dense, acid-proof brick set in some acid-proof cement such as Pecora, Fireite, Duro, or something similar.

Formerly tanks were installed with their tops flush with the floor. This had the disadvantage of not showing leaks as they developed, and rendering repairs, tightening of the bands, etc., impossible without dismantling. The old tubs were double—i.e., with an inner, brick-lined wooden tank set inside of an exterior and larger wooden tank, the space between the two being filled with a high-melting pitch. Tanks con-

structed recently are set above the floor level and have no exterior tank, but have small streams of water playing over the staves to keep them wet and swelled, since the heat developed during neutralization will dry the staves very rapidly otherwise. When installing such tanks it is necessary to subject the interior brick lining to a wash of weak acid to set the cement before actual use, since otherwise the cement will not become hardened sufficiently to resist the hydrostatic pressure and heat of operation during the first run.

Many types of gas distributors for these neutralizing tanks have been tried, including long glass tubes with small perforations on the bottom, chemical-ware hub-and-spoke, and Duriron, Tantiron and Corrosiron hub-and-spoke types. In tests of these comparisons have been made to determine life, yields obtained and relative costs both of construction and upkeep. The acid-resistant alloys have proved to be the best and are practically indestructible.

Operation of Neutralizing House

It is important to have as deep a "heel" as possible in the neutralizing tank to start with, and this should be calculated as the maximum allowable without overflowing the tank at the end of the run. Allowance must be made for the differences in volume of the various strengths of acid used. While tests have shown that very high yields can be obtained with comparatively strong acids, their use requires much more care, since the temperature in the neutralizing tub rises more readily in this case and high temperatures are, in general, conducive of low yields. The temperature should never be permitted to rise above 195 deg. F., since above this point a violent frothing occurs with evolution of nitrous oxide and loss in yield.

Each crock of weak nitric acid is carefully weighed and sampled before use, and at the end of the day the various samples are composited according to weights, and analyzed, so that a yield can be calculated monthly not only on the ammonia but also the acid efficiency.

The top of the neutralizing tub is covered, except for a small window for the operator to watch operations and dip out samples to test for neutrality. During the run, methyl orange test papers are used to determine whether a sample removed is acid or alkaline, but at the close of the run the exact end-point is found by taking a known quantity in a pipette, which is neutralized by a tenth-normal acid or alkali solution from a burette, with methyl orange solution as indicator, since this determination is much more delicate than the test papers. After a very short experience the operator can almost entirely dispense with the test papers, since the color of the solution in the tub is indicative of acidity or alkalinity. If a lemon color, the charge is acid, and if a chocolate-brown, it is alkaline. These colors are due to the small amount of iron present, the change being very delicate.

Occasionally during neutralization severe foaming occurs, which, if the tubs are being operated at capacity, may cause them to overflow. A small amount of petrolatum thrown into the tub will float on the top and obviate this trouble.

Recently, advantage has been taken of the fact that the principle of the heat exchanger can be applied to this operation just as easily as it has already been applied to others. If two stills are used, the gases from the one in operation are passed through the idle one, the latter acting as a condenser and also absorbing the heat from the gases which would otherwise be wasted in the cooling water of the condenser.

At the close of the neutralization, the tub is emptied by an acid-resisting cast-iron standpipe connected to a centrifugal pump which delivers the neutral liquor to storage tanks. Formerly the latter were made of wood, but more recently have been constructed of boiler plate, since the latter have the longer life, in spite of considerable rusting being experienced. The small amount of iron rust carried through the neutral liquors is of no disadvantage. In fact, it is a positive advantage in preventing the development of acidity during evaporation, as will be explained later. For this reason agitators consisting of air pipes are installed in these storage tanks to stir up the iron rust sludge and carry it through.

Evaporating Equipment

Experience in evaporation of neutral ammonium nitrate involves a variety of styles of evaporating pans, methods of heating, and theories regarding losses involved. Many shapes of pans have been used, both direct-fired and steam-heated. Steam coils with rust joints inside the pan, through-and-through coils of wrought iron, cast iron and steel, even Spellerized steel

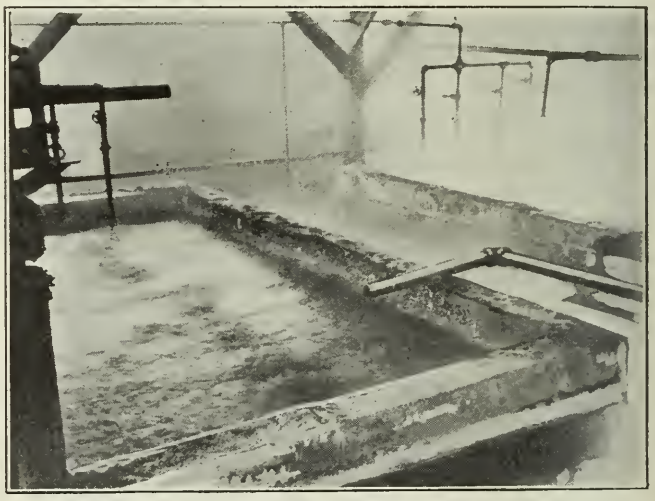

FIG. 4—EVAPORATING PANS

and aluminum, have been used. Experience has shown that in general liquors containing a considerable quantity of ammonium chloride act severely on wrought iron and steel, sometimes corroding through in one evaporation, while cast iron will stand this service. The latter are difficult to obtain in such lengths, and two shorter lengths have been carefully threaded and joined in the center. The air agitation should never be directed against a steam pipe, since the blast of air will cut through a steam pipe in this service in the course of a few hours. While no work has ever been done to prove the point, it is assumed that the air in the hot solution assists in the hydrolysis of the ammonium nitrate, carrying off the ammonia gas and leaving behind the nitric acid, which rapidly corrodes the metal.

One theory of this corrosion of the steam pipes is that the entire pan operates as a huge galvanic cell, the two elements being the dissimilar metals, steel and cast iron, the electrolyte being the ammonium nitrate solution. Insulation of the steam pipes from the pan

and measurement of the potential differences show an appreciable voltage, which supports this contention. Nevertheless, the corrosion does not take place in the absence of ammonium chloride.

Evaporating pans of the size in use at present contain about 8,000 lb. of a solution of about 50 per cent concentration. The steam pipes were formerly one continuous through-and-through coil, which had the disadvantage that a leak in the coil at any point stopped operations. At present there is a steam header at each end and each steam pipe in the pan is fed from this header by a small valve, so that a failure of any one pipe permits cutting this particular pipe out of service without interrupting the operation.

Operating Considerations in Evaporation

At elevated temperatures experience has shown that the loss in yield is directly proportional to the time the solution is held at the high temperature. Evaporation is therefore carried off as rapidly as possible.

The use of air agitation is required during evaporation on account of the severe foaming experienced without it. A slight current of air bubbling through the liquor from perforated air pipes breaks up this froth very effectively. A large air receiver is placed in the air line near the operation to separate the water always carried by compressed air. This reservoir prevents freezing of the air lines in cold weather, as well as insuring a supply of air for some time in case of failure of the main supply. Calculations will show that it is cheaper to install a small low-pressure rotary blower to furnish this air for agitation rather than to use high-pressure air and throttle down to the low pressure required.

It was formerly the custom to add small amounts of chalk or zinc oxide to the charge during evaporation to reduce the acidity developed and so protect the pan from corrosion. On account of the alkaline nature of these substances, ammonia gas was driven off with consequent loss in yields. It has been found that ferric hydroxide normally present in these solutions exerts the same effect without driving off ammonia gas, and therefore additional iron is now added in case insufficient is present.

To illustrate the extent to which losses may occur in evaporation during long periods of time we give below figures obtained experimentally by heating nitrate of ammonia in a constant temperature bath for 2 hours:

Temperature in Deg. F.	Per Cent Loss
330	3.53
320	2.65
315	1.66
300	1.14
290	1.00
280	0.53
270	0.40
250	0.21
230	0.10
210	0.00

On account of the hydrolysis mentioned above, charges can develop acidity during evaporation, but this change can always be recognized by the color of the charge. A lemon-yellow color indicates acidity, which can be confirmed by tests with methyl orange papers if any doubt exists. This acidity during evaporation may be corrected by the addition of the minimum quantities of chalk or zinc oxide necessary, bearing in mind that any excess drives off ammonia gas. The presence of small quantities of iron oxide or hydroxide in suspension will prevent this development of acidity and so protect the pan and steam pipes from corrosion. Small quantities of iron may be added to the neutralizing tub to furnish this hydroxide.

Operation of Crystallizing Kettles

The solution of ammonium nitrate is evaporated to a predetermined point and then drawn off into a water-jacketed crystallizing kettle having revolving arms and scraper blades so that the salt may be agitated during cooling, to produce the size of crystal desired. The determination of the proper temperature to which the solution in the evaporating pan must be carried is actually the determination of the freezing point of the charge. In actual practice some of the solution is removed in a dipper, a thermometer placed in it, and the material stirred by the thermometer while cooling. As the temperature falls, a point is reached where it remains practically stationary for a time as the liquor becomes thick and slushy. This pause in cooling is due to the heat developed by crystal formation. This point, and not the maximum temperature of the solution of ammonium nitrate, is taken as the criterion for the finish of the evaporation. Three factors influence the final size of the crystals obtained, (*a*) the temperature of crystallization, (*b*) the rate of cooling, and (*c*) the amount of ammonium chloride present.

FIG. 5—CRYSTALLIZING KETTLES

Two grades of ammonium nitrate are used in explosives—one a very coarse, sandy material, the other a rather fine powder. The former is made by carrying the evaporation to a higher point and permitting the liquid to run into crystallizing kettles heated by steam in the jacket. After the entire charge is in the kettle the steam is shut off and the charge permitted to cool naturally without the use of cooling water. This gives a slow rate of cooling with consequent formation of large, rounded crystals. When the fine product is desired the evaporation is not carried so high, and the charge is run into a warm kettle, which is then immediately chilled with cold water in the jackets, inducing sudden crystallization and consequently fine crystals. On cooling down to room temperatures the crystals, in forming, will give off sufficient heat to drive off all but about 0.05 per cent of moisture. This removal of moisture is important, since its presence in the finished ammonium nitrate would cause the latter to cake to a solid mass before

use, as well as causing difficulties in the dynamite made from it.

To diminish the tendency of ammonium nitrate to absorb moisture, 1 or 2 per cent of petrolatum is added while the material is still warm and before removal from the kettle, so that there will be a coating of grease over each crystal. To lessen the tendency to "cake" during storage, 1 or 2 per cent of kieselguhr may be added at the same point of the process. Before removal from the kettle 1 per cent of chalk is added as an antacid, but it should not be added until the charge has cooled down to about 120 deg. F., since otherwise a reaction will take place driving off ammonia gas with consequent low yields.

The finished product is stored in barrels lined with waxed paper, or in canvas bags, in a heated storeroom. Heat is necessary to prevent absorption of moisture by the deliquescent material. From this storehouse it is taken to the dope house of the dynamite line, where it is mixed with other ingredients, screened and incorporated with nitroglycerine to form "ammonia dynamites."

The above description does not cover the so-called "direct neutralization," a process which eliminates the use of the ammonia still. If sufficiently pure ammonia liquor is available there is no necessity for distilling, and the ammonia liquor can be run directly into the neutralizing tub. The process of evaporation remains the same as described above and the relative merits of the two methods have already been discussed.

Use of Ammonium Nitrate in Explosives

In recent years conditions abroad, especially as regards financial exchange, have become such that synthetic ammonium nitrate can compete with the same compound manufactured as described above. Synthetic ammonium nitrate is received in this country from Europe and is treated to prepare it for use in commercial high explosives as described in the first part of this article. Very recently a small amount of some material has been added to the synthetic ammonium nitrate when made which prevents solidification during storage and shipment, so that it can be readily dumped out of the cask when received. In this case it is only necessary to agitate in a warm crystallizing kettle to remove the moisture and wear down the crystals to obtain a fine product ready for use in explosives.

Not only does the use of ammonium nitrate effect a very considerable saving in the cost of the explosive but it renders such an explosive much more suitable for many operations by reducing the velocity of detonation to a marked degree, reducing thus the shattering and increasing the "heaving" effect, performing more useful work per pound of explosive used than would be the case without the ammonium nitrate present.

While under ordinary conditions ammonium nitrate cannot be detonated, in combination with nitroglycerine or other similar high explosive it actually does detonate, and with a strength apparently equivalent to about seven-tenths the strength of nitroglycerine. Many of the permissible explosives used in enormous quantities in coal mines contain as much as 80 per cent of ammonium nitrate because of the fact that the latter reduces the amount of flash produced on explosion and therefore reduces the tendency of the gas and coal dust to fire and ignite the mine.

Wilmington, Del.

Commercial Preparation and Use of Fullers Earth

By T. Poole Maynard and L. E. Mallory
Geological and Industrial Engineers

FULLERS EARTH can be defined as a highly siliceous clay, usually indurated, which has the property of adsorbing certain organic coloring matters from vegetable and mineral oils. This property, which defines the earth and is indicative of its value, can be determined only by actually filtering the oil in the laboratory.

The American earths have been found more desirable for the refining of petroleum, while the English earth has been regarded as better adapted for the bleaching of edible oils. American earths have been found of distinctly superior bleaching power to English earth with the vegetable oils as well, but they have failed to displace the English earth on account of the dependable uniformity of the imported earth, thus assuring the refiner a standard of bleach, uniform filtering and reliably low oil retention properties.

Very little has been published regarding the treatment and preparation of the English earth, but it has recently been determined by the writers that certain of the American earths can be commercially prepared, so that the bleaching properties, filtering and oil adsorption are equally as dependable and these qualities found more desirable than those of the English earth.

Occurrence, Origin and Physical Character

Fullers earth is found in this country in seventeen states, but has been developed only in Florida, Georgia, Arkansas, Texas, California, Alabama and Massachusetts. Florida leads in production, with Georgia second. The Florida earth is used largely in the refining of mineral oils on account of the high specific volume of the earth.

Recent investigation by the authors has revealed extensive commercial deposits of superior bleach to any other known earths.

Fullers earth deposits are found in the more recent geologic formations, being Post-Paleozoic. The deposits represent originally calcareous clays of marine origin which have since their deposition been elevated into land areas and subjected to compression, alteration and erosion. The consolidation of the deposits under pressure and the leaching out of the lime has been followed by secondary enrichment of the silica, largely as colloidal silica and colloidal aluminum silicates.

Fullers earth is characterized by its light weight, due to the proportion and nature of the pore space. Sand in varying amounts is usually present as well as some mica and in places calcium carbonate in the form of fragments of shells. The earth is conchoidal in fracture, usually indurated and does not slake in water. It is brittle and not plastic until ground. The earth varies in color from gray to blue, and brown to greenish and yellow. The yellow earth has passed through extreme processes of oxidation and in some areas the yellow oxidized earth proves to be of superior bleach.

Although fullers earth has a true specific gravity about equal to that of other clays, it is so porous in nature that when thoroughly dry most samples will float in water, showing the presence of more than 50 per cent voids.

Chemical analyses have never been regarded as of ıy particular value in arriving at an interpretation the possible value of the earth for commercial use. n ultimate analysis, beyond showing the quantity of ɔssibly objectionable impurities as lime and pyrite, is ithout much meaning. A determination of hydrous lica and of the aluminum silicates, which would in fect constitute the colloidal content, often may be of rect value.

The total silica in different earths may vary from ss than 50 per cent to even more than 80 per cent; ıe alumina is always low, usually from 5 to 20 per ent; the combined water, from 5 to 12 per cent, is ɔout that of the more siliceous clays. These are the ore important constituents and any others may be ɔnsidered as adulterants, sometimes harmful. Lime ıd magnesia are nearly always present and the iron ɔntent is usually evidence of secondary enrichment. he alkalis in many of the commercial earths do not tal more than 1 per cent. The mechanically carried ater (moisture) is high, even more so than in most ays, and there is the same tendency to absorb mois-ıre in storage.

Bleaching Power

The bleaching power of fullers earth is the basis of s commercial use. Several theories have been put ɔrward to explain this action. Like many other colloid ecularities, it is due to a combination of mechanical ıd electrical properties, with chemical action elimi-ated from consideration only by nice differentiation. is a combination of adsorption and mechanical filtra-on, accompanied by some chemical disintegration due selective adsorption.

The active constituents of the earth are probably ydrous silica and hydrous aluminum silicates. The ɔrous nature of the earth, due to the fact that it is uilt up of grains approaching colloidal size, offers a rge active surface.

The driving off of the combined water does not irectly affect the bleaching properties of the earth, but ıis may require temperatures that will destroy a por-on of this power by a reduction in surface as the inkering stage is reached. Coarsely ground earths sed in the bleaching of petroleum oils are not affected their bleaching properties when the water of com-ination is driven off, while the very finely divided arths used in the bleaching of vegetable oils have their each more materially injured by driving off the com-ined water.

Use in Petroleum Oil Bleaching

A few earths can be used for bleaching both mineral ıd vegetable oils, while most of the earths are by ature limited to one field or the other. In the bleach-ıg of mineral oils an earth of high specific volume is ore in demand, while in the refining of vegetable oils arths of lower specific volume are more desirable.

The methods of preparation of earth for the bleach-ıg of mineral oils and vegetable oils are quite differ-ıt. The preparation of the earth for the bleaching mineral oils is much nearer standardization.

The earth is graded for bleaching mineral oils ccording to the nature of the oil to be treated. The ore common gradings are 30 to 60 and 60 to 80 esh, while there is some demand for 15 to 30 and inus 80 mesh. The earth is burned at a low heat to emove moisture and combined water and then placed in large cylindrical containers. The oil is percolated through under pressure, if necessary. When the oil runs too dark, the earth is washed as free of oil as practicable and burned in rotary kilns. The number of times an earth may be re-used depends mostly upon the resistance that it shows to breaking down in burning and handling; with 25 to 30 per cent loss the earth is re-used as much as ten times. The quantity of oil bleached by a ton of earth of course varies widely; with medium oils a total of 250 bbl. per ton of earth is good practice.

Bleaching Vegetable Oils

In the refining of vegetable oils, the crude oil is heated and treated with an alkali to remove the fatty acids and convert the coloring matter to the basic form. The oil is usually bleached at approaching the boiling point of water by stirring in from 1 to 5 per cent of the earth. Moisture, either in the earth or in the oil, interferes with the process. The hot oil, with the fullers earth in suspension, is then forced through a filter press. Following this, the oil is put through a deodorizing process. The refining then varies depending on the use to which the oil is to be put and upon the particular process of manufacture. Some processes include a second bleaching with a mixture of fullers earth and carbon black. The oil usually starts the bleach with slightly alkaline reaction and finishes the process somewhat acid.

The amount of earth used, from 1 to 5 per cent, is determined by laboratory control for the bleach required. The filter cake is usually washed with steam, hot water, air or various combinations of these. The cake is then wasted with any retained oil. As the earth tends to oxidize the oil, the cake must regularly and carefully be disposed of. Some earths cannot be used, as they oxidize the oil so rapidly that it takes fire in the presses.

The earth is prepared by drying and grinding 70 to 100 per cent through 200 mesh for the vegetable oil bleach. This fineness of grinding depends or should depend upon the producer's understanding of the individual characteristics of his earth. A finely porous earth requires less grinding to develop the necessary bleaching surface. The grinding is further limited by the behavior of the earth in the bleaching kettles, in the pumps and in the filter presses. Furthermore, each earth possesses a natural limit in bleach beyond which it requires much more than a relative increase in bleaching surface, whether by finer grinding or an increased percentage of earth, to obtain another point or two in bleach. A little calculation makes this understandable. One pound of commercial fullers earth offers a bleaching surface of several hundred square feet. Six per cent of this earth thoroughly stirred through the oil gives an oil film thin enough to compare closely with recently determined films of lubricating oils. The effectiveness of the earth at this concentration should be rapidly approaching a limit.

Losses of Material During Use

Fullers earth found its first commercial use in removing oil from woolen cloth. This property of absorbing oil is inherent in the earth.

In the refining of vegetable oils in 1921 nearly $2,000,000 worth of cottonseed oil was thrown on the waste dumps in filter cake. These oil losses run from 15 per cent of the weight of the earth used to more

than 30 per cent. At the lower figure they exceed in cost the value of the fullers earth. The refiner endeavors to reduce the losses of oil by scouring the cake and experimenting to find commercial means of recovery. The producer can bring his brand of earth into favor by lowering the oil losses with his earth as much as is practicable.

These losses may be divided into three more or less determinate parts.

1. Loss in oil film.
2. Loss by absorption in the pores of the earth.
3. Loss in small and inaccessible voids between the particles.

In a well-washed cake the loss in oil film should not amount to more than 10 per cent of the total loss; the loss by absorption of pores in the earth is a property of the individual earth, though it can often be lessened by proper grinding; the third and often largest factor can be regulated more directly, although a separate problem for each type of earth. The use of the best-adapted system of grinding or the proper combination of two or more systems of grinding makes possible the grading of particles that will reduce these inaccessible voids in the cake to a minimum, while in no way interfering with the filtering properties of the earth.

The authors have recently put through a wide series of commercial tests on certain earths with oil losses markedly lower than with other earths and with bleaching properties superior to those of the standard English earth.

Extent of Market and Possible Developments

The consumption of fullers earth in this country has had a very rapid growth during the past 6 or 7 years and now amounts to more than 150,000 tons annually, of which less than one-fifth is imported. While there are extensive deposits of earth, particularly in the Southern States, and some comparatively large developments have been made, the demands of industry have kept in advance and have resulted in a steady increase in price. Under this stimulus production will grow until it will be another incident in "the survival of the fittest" with the superior earths or superior processes controlling the market.

There is a possibility of a widening market in making cheap "clay pigments" due to the property of fullers earth of strongly adsorbing basic dyes. The property of adsorbing bases gives it a real value as a commercial and simple water "softener." The earth when freed of sand and properly ground is in good standing as a filler, particularly in the rubber trade. The "fines" now wasted in the preparation of the earths for the mineral oil trades may be utilized, by further preparation, for the uses above mentioned.

Carbon blacks, calcined bauxite, prepared lignite and infusorial earth are also used in the refining of oils and sirups. It is possible that fullers earth under modifications of present processes, where necessary and practical, may replace some of these materials.

Summary

Fullers earths are widely distributed in this country, particularly in the Southern States.

In arriving at the possible value of an undeveloped earth a geological interpretation of its origin is of primary importance. Determination by chemical analysis of hydrous silica and aluminum silicates may have scientific value in predicting bleaching quality.

A relative determination of bleaching surface due to porosity may be made by comparing the bleaching power of an earth at different finenesses. This may be used as a base to determine nature of grinding required not only to develop bleach but also to control oil absorption.

Commercially feasible developments are dependant on location with respect to transportation; inherent superior qualities of the earth; preparation that develops these natural advantages for a particular market, and then technical control of the product. Only by a combination of these essentials can a reliable, uniform, dependable, superior commercial earth be prepared.

Our investigations show that while American earths of superior bleach to standard English earth are on the market, yet the excessive oil retention of these earths resulting from a lack of proper grinding and technical control have prevented them from occupying the position they should have.

Earths of dependable uniformity are available and eminently satisfactory to the mineral oil refineries. However, the large amount of "fines" resulting from grinding and which cannot be used by this trade and which materials are now largely wasted can be utilized and established in other trades by their proper preparation, at values equal to the earth shipped to the oil refineries. The present losses are wasteful and inexcusable.

While the markets and the value of fullers earth have been growing rapidly, the producer for the mineral oil on the one hand has paid little attention to his byproduct in the way of "fines" and the producer of the vegetable oil bleach on the other hand has not developed the all-around desirable earth that his market demands.

With the growing knowledge of the needs of the industries, technical control of production is the next step in development and will lead to markets otherwise beyond attainment or even conception.

Atlanta, Ga.

Recent Hydro-Electric Development in Canada

The Canadian Department of the Interior has been analyzing the waterpower resources of the dominion for the past two years.

Last year was one of substantial progress, there having been brought into operation new installation to the extent of 300,000 hp. The installed waterwheel capacity now totals to 2,763,000 hp.

The 2,763,000 hp. thus far installed throughout the dominion is apportioned to the following uses: 2,013,000 hp. in central electric stations for general distribution purposes, such as operation of street railways, operation of mines, operation of electrochemical and electrometallurgical industries, operation of pulp and paper mills and for general industrial and domestic uses; 476,000 hp. installed in pulp and paper mills. In addition there is used in the pulp and paper industry 161,000 hp., purchased from the central electric stations installation; 274,000 hp. installed in industries other than central electric stations and pulp and paper mills. The total installation for the dominion averages 315 hp. per thousand of population, a figure which places Canada second only to Norway in the per capita utilization of water power among the countries of the world.

Selective Case-Carburizing

A Review of the Various Methods of Producing Local Cases—In General, Electrodeposited Copper Has Furnished the Best Protection—A Non-Metallic Coating Whose Application and Removal Present No Great Difficulties Is Described

By W. P. WOOD* and O. W. McMULLAN

ON A GREAT many occasions it is desirable to obtain surfaces of varying hardness upon the same piece of steel. A camshaft is a good example of this, inasmuch as it is desirable to have the surface of the cams hard and resistant and the intervening bearings, etc., much less hard. This object is usually accomplished by case-hardening the surfaces of the cams, leaving the bearings without the carburization. Such a procedure may be termed selective case-carburizing.

Selective case-carburization is due to:

1. Desire to leave some parts soft for riveting or fixing purposes.
2. Desire to leave parts soft that are to be subsequently machined, and which are adjacent to case-carburized parts.
3. Desire to produce hard wearing surfaces alternating with softer surfaces.
4. Desire to maintain the interior of tapped holes in a soft condition.
5. Desire to leave axle shafts or spindles soft in the middle so as to straighten or set them after hardening.
6. Desire to maintain threads true and soft. As a rule, when a threaded part is case-hardened, it becomes warped and thrown out of center with the ground surface of the rest of the piece.

The advent of the motor car industry has brought about great changes in the old methods of case-carburizing and it is in this industry where the desire to obtain localization of case-carburizing is most frequent. This of course means that there was but little occasion for securing selective case-carburizing until the last few years. If much experimental work has been done, it has not been published, for very little is to be found in the literature concerning it, and apparently no résumé of the entire subject has been heretofore attempted.

The requirements for the production of localized cases are essentially simple. It is well known that carburization is brought about through a cycle of reactions in which carbon monoxide acts as the carbon carrier. In order then that no case be formed, it is only necessary to produce a coating upon the surface of the steel which is impervious to carbon monoxide. The difficulty arises in producing a coating which is unaffected by the high temperature of carburization and one which is reasonably easy to remove.

Classification of Methods

Methods may be divided into a few general classes according to the nature of the "resist" used in obtaining the desired soft spots:

I. Metallic coatings.
   1. Thin plate of copper produced by dipping in or rubbing with $CuSO_4$ or $CuCl_2$.
   2. Thin plate of copper produced by electrolysis.
   3. Thin plate of nickel produced by electrolysis.
   4. Thin plate of tin produced by electrolysis.
   5. Coatings of metals produced by Schoop spray process.
   6. Coating of steel, produced by shrinking on a thin steel sleeve.

II. Non-metallic coatings.
   1. Clay, loam, asbestos wrappings.
   2. Fire paints enamel.
   3. Mixtures of clays and other inert substances.
   4. Mixtures of sodium silicate with clays, calcium hydrate, sand, and others.
   5. Putty.

III. Leaving parts oversize, and grinding off case.

IV. Packing pieces in contact at desired soft surfaces.

Metallic Coatings

A thin copper plate produced by dipping or rubbing with $CuSO_4$ has not in general proved suitable. It was originally developed from the work of de Dion-Bouton.[1] Brearley,[2] and Guillet and Bernard[3] make rather unfavorable mention of this method.

A most generally used and successful method of producing local cases is by a copper coating deposited electrolytically from a cyanide bath. (A bath of $CuSO_4$ is recommended by some.) Probably the most extensive work upon electrolytic copper coatings has been done by Guillet and Bernard.[3,4,5] They state[3] that a thickness of 0.01 mm. is sufficient for carburization at 850 deg. C. but 0.02-0.03 mm. is required at 1,000 deg. C. There is some danger of diffusion of the copper under some circumstances,[4] but this is not of much importance. Giolitti[1] states that the use of copper coatings can be successful only below 950 deg. C.; Lothrop[6] states that a thickness of 0.0005 in. is required; Harbee[7] mentions a thickness of 0.001 in. as preventing the action of the most vigorous carburizers; Keachie[8] is of the opinion that a thickness of 0.002 in. is required, while Zimmerli[9] maintains that a thickness of only 0.0004 in. is necessary. Other writers who discuss the utility of copper coatings are Brearley,[2] Giolitti,[10] Tiemann,[11] E. F. Houghton Co.[12] Jones,[13] Gleason,[14] Paxton,[15] Grant,[16] Edwards[17] and Van Deventer.[18]

Coatings of nickel and tin have not been generally successful.[2,3,4,10,13] Guillet and Bernard[5] state that carbon monoxide will pass through any nickel coating and that tin is unsatisfactory unless on a horizontal surface where it will not run off. Paxton[15] mentions nickel plating as a satisfactory means of preventing case-carburizing.

The application of the Schoop spray process in applying coatings is discussed by Guillet and Bernard.[3,5] The apparatus is rather expensive and a thicker coating is required.

Giolitti,[1] Brearley[2] and Grant[16] describe the method

*Assistant Professor of Chemical Engineering, University of Michigan.

of producing local carburization by means of a soft steel sleeve. This sleeve must be thin so that it will be brittle after the carburizing operation and may be broken off by tapping with a hammer.

Requirements of Non-Metallic Coatings

Non-metallic coatings usually include mixtures of clays, sodium silicate, sand, calcium hydrate and many other substances. Clays or sodium silicate alone are not successful, but some of the mixtures using sodium silicate as a base have been partly successful. Nearly all the writers have gone more or less at length into their use. Giolitti[1] quotes Grenet to the effect that putty is useful in preventing carburization.

A non-metallic coating should fulfill the following requirements:

1. Easily applied through painting on with a brush or as a paste.
2. Will not shrink or crack.
3. Will not melt or peel off when heated.
4. Will not become porous and permit passage of carbon monoxide at high temperatures.
5. Easily removed after carburizing treatment is finished.
6. Material and operating cost low.

Experiments on Coatings

The attempt to discover such a coating was of a rather routine nature involving intelligent selection of material and a large number of trial runs. The same carburizer was used throughout, being the so-called rapid mixture produced by the Parke Chemical Co. of Detroit.

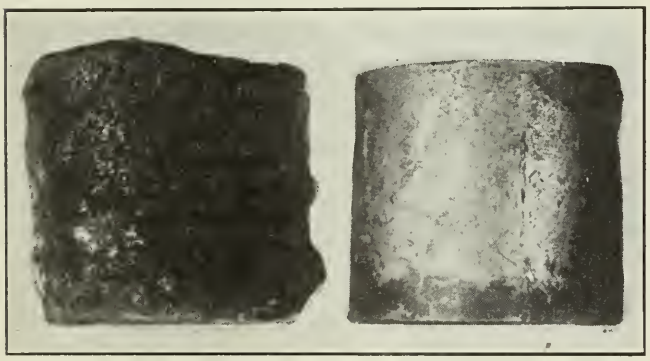

FIG. 1—SAMPLE AS REMOVED FROM FURNACE, AND AFTER DIPPING IN MOLTEN SODIUM HYDROXIDE

Samples were heated in an electric furnace, pyrometrically controlled, usually at 1,700 deg. F., which might be considered as an average case-carburizing temperature. The time ranged from 2½ to 24 hours at the above temperatures, as indicated in the table of results. Samples were of plain 0.11 carbon steel in the form of a cylinder ¾ in. diameter and about 1 in. long, coated to various depths about half way round with the mixtures. Fig. 1 shows a sample with its coating. These samples were placed in a threaded steel tube, 2 in. in diameter and 6 in. long, closed by screwing a cap on each end. Usually more than one sample was placed in the tube at a time, in which case they were separated from one another by the carburizer with which the tube was filled. The closed tube was then placed in the furnace. Fresh case-hardening compound was used for each run. Before applying the coating some of the samples were polished on a fine grinding wheel, while others were not, but this did not seem to affect the adherent or protective properties of the mixture. After removal from the furnace the samples were permitted to cool in the tubes, after which they were removed, cut, polished, etched and examined under the microscope.

Table I contains a summary of the results. Various thicknesses of the same material were tried. In making the mixtures all dry substances were finely ground and then mixed with the base, either sodium silicate or clay. Water was then added until a good smooth paste

TABLE I—SUMMARY OF CARBURIZING EXPERIMENTS

Thickness of Coating, Mm.	Coating Material	Time, Hrs.	Temp., Deg. F.	Results
0.3	Sodium silicate	3½	1,700	Protected
0.5	Sodium silicate	3½	1,700	Protected
1	Sodium silicate	3½	1,700	Protected
2	Sodium silicate	3½	1,700	Protected
2	1 Flint clay:3 sodium silicate	4	1,700	Protected in spots only
2	1 Flint clay:1 sodium silicate	4	1,700	Thin case formed
2	3 Flint clay:1 sodium silicate	4	1,700	Not much protection
1.5	Flint clay	4	1,700	Not much protection
2	1 Flint clay: 3 sodium silicate	6	1,700	Protected in spots only
0.3	MgO+sodium silicate	6	1,700	Protected
0.3	Sodium silicate	6	1,700	Protected except where coating scaled off.
0.3	Sodium silicate	6	1,700	
0.3	Sodium silicate	8	1,700	Thin case formed
0.5	Sodium silicate	8	1,700	Cased in spots
3	Portland cement + sodium silicate	8	1,700	Not much protection
1	Sodium silicate	6	1,700	Protected
2	Calcined flint clay	6	1,700	Cased
1	MgO + sodium silicate	6	1,700	Results not good
2	1 Flint clay:3 sodium silicate	6	1,700	Protected except one spot
1.5	*1 MgO:3 sodium silicate	6	1,700	Cracked. Not protected
1	1 MgO:20 sodium silicate	6	1,700	Protected, but tends to crack
2	1 calcined flint clay:1 sodium silicate	6	1,700	Gives a case
2	3 Calcined flint clay:1sodium silicate	6	1,700	Gives a case
1	1 Asbestos:5 sodium silicate	6	1,700	Mostly protected. Asbestos was too coarse
2	1 Al_2O_3:2 sodium silicate	6	1,700	Protected
0.3	1 Silex:2 sodium silicate	6	1,700	Cased. Layer too thin
1.5	A commercial selective carburizing compound	6	1,700	Cased in two or three spots
1	1 Pb_2O_3:2 sodium silicate	6	1,700	Cased in spots
0.5	1 ZnO:2 sodium silicate	6	1,700	Slightly cased. Layer too thin
1.5	1 Plastic clay:1 Al_2O_3:1 sodium silicate	6	1,700	Cased in spots
3	A commercial selective case carburizing compound	6	1,700	Thin case formed
1	1 Asbestos:3 sodium silicate	6	1,700	Good protection
1	1 Silex:2 sodium silicate	6	1,700	Cased in spots
0.2	1 Al_2O_3:2 sodium silicate	6	1,700	Cased in two small spots
1.5	1 Al_2O_3:1 plastic clay:2 sodium silicate	6	1,700	Cased in spots
2.5	1 Al_2O_3:1 sodium silicate	6	1,700	Thin case formed
2	1 ZnO:2 sodium silicate	6	1,700	Cased
2	3 Plastic clay:1 sodium silicate with outer layer of sodium silicate	6	1,700	Peeled off in furnace
1.5	1 Plastic clay:1 sodium silicate	6	1,700	Cased
0.5	1 Asbestos:3 sodium silicate	6	1,700	Good protection
1.5	1 Plastic clay:1 sodium silicate with outer layer of sodium silicate	6	1,700	No case. Sticks on
1	1 Plastic clay:2 sodium silicate	6	1,700	Cased in spots
0.3	1 Al_2O_3:3 sodium silicate	6	1,700	Cased in spots. Layer too thin
1	1 Asbestos:3 sodium silicate	6	1,760	Good protection
1	1 Kaolin:2 sodium silicate	6	1,760	Cased
0.7	1 Asbestos:2 sodium silicate	6	1,760	Protected
1.5	1 Asbestos:3 sodium silicate	8	1,825	Protected
0.5	1 Asbestos:2 sodium silicate	8	1,825	Protected
2	3 Calcined flint clay:1 sodium silicate with thin outer layer of sodium silicate	6	1,760	No case. Sticks on

Fig. 2—Case after 8 hr. at 1,700 deg. F. in unprotected sample.

Fig. 3—Protected by 1 asbestos plus 3 sodium silicate; after 8 hr. at 1,700 deg. F.

Fig. 4—Protected by 1 alumina plus 3 sodium silicate; after 24 hr. at 1,750 deg. F.

was obtained. The coatings were permitted to dry in the air until hard enough to prevent being pushed out of place when handling. Too rapid heating will leave the dried coating full of bubbles, which permit the passage of carbon-carrying gases.

First layers of various thickness of pure sodium silicate were tried. When the water solution of sodium silicate was thin enough so that it could be readily applied, surface tension forces pulled the silicate into drops, making an even coating difficult to obtain. When the solution was made thicker, it also became very viscous. Pure silicate offered good protection against carburizing except when the pieces were in the furnace for a long time, when it would scale off in small spots, there permitting carbon penetration. Ordinary clay is porous and permits the penetration of gas at high temperatures and also tends to shrink, crack and peel off.

Adulterant for Sodium Silicate or Clay

The problem at this stage was narrowed down to finding something to mix with sodium silicate to make it more rigid and prevent surface tension action, or to mix something with clay which would fill up the pores and prevent the passage of gas.

Of those substances mentioned in the literature, the following were found to be unsatisfactory if any good degree of protection is desired: Clay and its various mixtures, mixtures of kaolin and sodium silicate, putty, hydrated lime and sodium silicate, sodium carbonate and sodium silicate, sodium borate and sodium silicate.

Tests with a commercial local carburizer were made, the directions being carefully followed. All experiments showed more or less carburization. This particular method also required a good deal of time and care in mixing, applying and drying the coating. No test was made on the mixture of 50 per cent sodium silicate, 25 per cent china clay, 18¾ per cent amorphous silica and 6¼ per cent fine silver sand specified in Whyte's patent, it being considered that this mixture was unnecessarily complicated and because of the fact that no mixture was found to give perfect protection when the amount of sodium silicate was as low as 50 per cent. Copper plating produced both by dipping in copper sulphate and electroplating from a cyanide bath were tried. Dipping was found to give a porous, loosely adhering layer which did not give good protection. Electrodeposited copper plate gave good protection, as has been abundantly demonstrated by many workers.

Of these mixtures tried only two were found to be satisfactory. Finely ground asbestos and sodium silicate gave perfect protection whenever the percentage of sodium silicate was 67 or more. Aluminum oxide and sodium silicate mixtures give about equally good protection, but the coating needs to be thicker than that for the asbestos mixture. The method of preparing and applying these coatings has been mentioned previously. Different percentages of asbestos and sodium silicate were tried in order to ascertain between what limits protection was to be had. It was found that when the amount of asbestos became greater than one part in three by weight, the protection became imperfect, while the lower limit becomes one of viscosity—that is, the mixture is not plastic enough and does not stick.

Twenty-four-hour tests were made, showing that 1 mm. of the asbestos-sodium silicate mixture gives protection at 1,750 deg. F., while it requires a thicker layer of the aluminum oxide-sodium silicate mixture to give equally good protection. Tests carried out at a temperature of 1,825 deg. F. showed that these coatings also afforded good protection at this higher temperature.

Experiments made on practically carbonless ingot iron showed the protection with 1.5 mm. asbestos-sodium silicate mixture to be as complete as that with a coating of electrically deposited copper, the two samples being in the same container for 10 hours at 1,700 deg. F., and therefore under exactly the same conditions.

Removal of Protective Coating

It was found that all coatings that gave any good degree of protection adhered firmly to the piece after carburizing and if it were desired to have the surface of the carburized piece absolutely smooth and clean the coating could not be removed satisfactorily by pounding with a hammer. This was to be expected, since if the coating did not adhere firmly, it would probably permit the passage of gas between it and the steel, which would result in carburization. An attempt was made to put on first a layer of material such as clay (which would come off readily after carburizing) and after permitting this to dry somewhat, put on a second layer which would be impervious to the carburizing gases. Where the inner coating was such that it would come off readily, the compound coat was also liable to crack and peel off. The process also took much longer because of the extra coat, so was not very satisfactory when viewed from any angle.

The best method for removing asbestos- or alumina-sodium silicate coatings is to dip in molten sodium hydroxide. A sample which had one etched surface before being immersed still showed the crystal grains under the microscope, showing the sodium hydroxide to have practically no corrosive action on the steel. Fig. 1 shows two samples, one with a coating and one from which the coating has been removed by this means.

Another method is to quench the piece in water. If one quenching does not remove the coating completely, it can be given a second quench, or the small remaining portion can be quickly dissolved off in sodium hydroxide. Heating in molten calcium chloride so softens and disintegrates the coating that it can be removed by quenching once in water directly from the bath or by mere immersion when cold. The above methods were carried out with the coatings of alumina-sodium silicate and asbestos-sodium silicate mixtures.

Preventing Decarburization

The effectiveness of the mixtures in preventing decarburization of high-carbon steel and white cast iron was tested. The first samples were placed in the electric furnace without any material surrounding them. Under these conditions the coating tends to soften and run to a certain extent, making it rather thin in places. Thinking that some surrounding material would prevent this, samples were placed in one of the tubes mentioned above, used in carburizing, and packed in gravel so that the conditions would approach those of the samples when carburizing. Even under these circumstances the coatings fused to a certain extent and decarburization was again not entirely prevented.

Summary and Conclusions

1. A review of the literature establishes the fact that an electrolytically deposited plate of copper furnishes the most satisfactory metallic coating to produce localized case-carburizing. Under many circumstances and conditions this method is the most satisfactory one to use.

2. Non-metallic coatings have not heretofore proved generally successful under all conditions and experimental work with various mixtures which have been recommended in the literature has shown that they are not uniformly successful.

3. A non-metallic coating consisting of definite mixtures of sodium silicate with either finely ground asbestos or alumina furnishes good protection from carburizing conditions. It is easily painted on the metal and may be removed by immersion in molten sodium hydroxide or by quenchings in water. Calcium chloride in the molten state is also useful in loosening these coatings.

It is not felt that these coatings have universal application, but it is believed that there may be many times when their use may not only be possible but also profitable in heat-treating shops.

4. The coatings mentioned above are not as efficient in preventing decarburization as they are in preventing carburization.

Damages Awarded Where Injunction Against Discharge of Waste Was Denied to Aid War

In the case of E. G. Temple vs. E. I. du Pont de Nemours & Co. the complainant brought suit to restrain the defendant company from discharging its waste material into Bailey's Creek, which ran along his premises for about a mile, situated in Prince George County, Virginia. In 1915 the company established on the opposite side of the creek from complainant's lands a guncotton plant which employed at times as many as 25,000 men and used daily about 90,000,000 gal. of water.

The waste products of this operation, consisting in part of refuse cotton and other substances impregnated with poisonous chemicals, were carried into the creek, and it was claimed the navigability of the stream was greatly impaired and its waters polluted. Complainant sought to enjoin the du Pont company against discharging its waste material into the stream and to require it to clean out the creek and restore the waters to their natural state.

After the suit was begun war with Germany was declared and while the United States District Court at Richmond, Va., held the suit was properly instituted, it refused an injunction in view of the probable consequences of closing down the plant in face of the war and considering the public interest involved. Instead of the restraining orders demanded by the plaintiff, the court awarded damages to complainant in the sum of $8,500, and this decision was later upheld and affirmed by the United States Circuit Court of Appeals. Froth Flotation Tests on Bituminous Coking Coal

A Study of the Applicability of Froth Flotation to the Treatment of Fine Sizes of Bituminous Coal From Wilkeson, Wash., Including Various Experimental Arrangements of Roughing and Cleaning Operations for Best Ash Removal

By OLIVER C. RALSTON* and GAICHI YAMADA†

THIS research is the second undertaken in connection with a study of the applicability of froth flotation to the treatment of the fine sizes of coals of the Pacific Northwest. It forms a part of the coal-washing program of the Northwest Experiment Station of the Bureau of Mines in co-operation with the University of Washington, at Seattle. The first paper, by A. P. Wichmann and Oliver C. Ralston,[1] reviewed the past work on the flotation of coal and reported a number of experiments made to test the applicability of the process to the coals of the Pacific Northwest.

This paper reports the results of tests made to ascertain why the tests in the first research gave such poor results when finely ground coal was treated. It is naturally to be expected that fine grinding should better liberate the ash from the pure coal substance, yet flotation of the finely ground coal gave "dirtier" concentrate than flotation of relatively coarse coal.

The experiments consisted of a series of sink-and-float tests on the raw coal to ascertain the fineness of crushing necessary to liberate the maximum amount of ash and to provide a standard of permissible ash in the coal concentrate to be made by flotation; a series of tests on flotation of coal ground very fine under water in a pebble mill to test a number of oils and to determine the efficiency of flotation in removing the ash of this coal under the most extreme conditions; a series of tests on dry-crushed coal to compare with the wet-crushed material and also to determine the effect of size of crushing; and, finally, a number of tests operating on a definite flow sheet with roughing and cleaning operations in various combinations to see if a clean finished product would be made.

The sample of coal used for these tests came from, the No. 3 bed of the Wilkeson mine at Wilkeson, Wash. It consisted of the material passing a $\frac{3}{8}$-in. screen in a large screen test of the raw coal from this mine. The coal of this mine is normally crushed and washed before passing to beehive coke ovens.

Sink-and-Float Tests

A 20-kg. sample was crushed in rolls, removing oversize with a 35-mesh screen and returning to the rolls, and recrushing till all the sample passed through the screen. One kilogram of this material was used for a screen test (Tyler Ro-Tap) and each of the sizes was treated by the sink-and-float test commonly used in connection with coal washing, using a solution of zinc chloride of 1.34 sp.gr. to float the clean coal and allow the ash to sink. Previous work on coarser sizes of this coal had shown that the coal was somewhat "bony" and the cleanest particles contained about 7 to 9 per cent ash. Had the coal been cleaner, a zinc chloride solution of 1.30 sp.gr. would have been used.

Ten grams of each size of coal was placed in a 200-c.c. capacity separatory funnel and about 100 c.c. of zinc chloride solution of 1.34 sp.gr. was poured into the funnel. After 1 minute of shaking in order to mix and wet the sample the funnel was allowed to stand 12 hours in order to permit the heavier particles to sink to the bottom and the lighter materials to rise to the surface. Manipulation of the stop-cock then permitted separate collection of the sink product and of the float product. These were thoroughly washed with slightly acidulated wash water until no trace of zinc was found in the filtrate. The sample was then dried in an electric oven at 70 deg. C., weighed and analyzed. The screen analysis and the sink-and-float tests on this material are shown in Tables I and II, all figures being calculated on a moisture-free basis. The assumption was made that the material consisted of pure coal, ash and moisture. The latter two were determined and the pure coal was then calculated by difference.

TABLE I—SCREEN ANALYSIS OF WILKESON BED NO. 3 COAL, CALCULATED ON MOISTURE-FREE BASIS

Size—Meshes Per In.	Average Diameter, Mm.	Weight, Per Cent	Ash, Per Cent
Original—35	...	100.00	23.35
On 48	0.356	19.9	24.95
On 65	0.252	20.1	24.74
On 80	0.184	10.3	23.63
On 100	0.153	11.1	23.37
On 150	0.126	4.7	23.52
On 200	0.087	22.2	23.05
Through 200	0.074	10.7	23.48

TABLE II—SINK AND FLOAT TESTS, MOISTURE-FREE BASIS

	Float in ZnC_2 Solution, Sp. Gr. 1.34			Sink in $ZnCl_2$ Solution—		
Size, Mesh	Weight, Per Cent	Ash, Per Cent	Recovery Per Cent	Weight, Per Cent	Ash, Per Cent	Elimination of Ash, Per Cent
On 48	56.86	9.41	69.16	43.14	46.65	78.9
On 65	60.49	12.43	71.85	39.51	47.40	74.2
On 80	62.65	10.11	72.87	37.35	39.90	72.1
On 100	59.75	8.69	70.38	40.25	42.98	76.9
On 150	61.37	9.66	71.68	38.63	43.20	73.8
On 200	56.12	9.90	64.65	43.88	37.08	74.6
Through 200	49.30	16.12	52.95	50.70	27.52	63.7
On 200	64.18	12.25	62.50	35.82	40.86	65.01
Through 200	63.20	17.84	66.25	36.80	28.09	47.85

From Tables I and II the following conclusions can be drawn: The ash is about equally distributed in all the sizes of the coal, indicating that fine grinding, at least to 200 mesh, liberates little or no more ash than grinding to pass a 35-mesh screen; the cleanest coal contains about 8.69 per cent ash and on an average it is mechanically feasible to obtain 70 per cent of the combustible matter in the form of a 9 to 10 per cent ash product.

High inherent ash is characteristic of the coals of the Pacific Northwest, particularly the lower grade ones. Just why the more lignitic coals should have higher ash

than the anthracitic ones, even in the same field where part of the field has been altered into anthracite by local metamorphism, is not easy to understand. The true lignites of Nevada, California and Oregon are all very high in ash, so that they have frequently been considered of no value whatever and have been more or less neglected and are consequently not well charted nor described in the literature. The inherent ash in these coals is quite evidently too finely disseminated to be liberated by any ordinary commercial type of grinding. This has been revealed by both the sink-and-float tests we have carried out and by the froth flotation tests reported later in this paper.

Tests Under Reduced Pressure

The ash content of the float fractions of the material which passes a 200-mesh screen in the tests reported in Table II shows that the ordinary sink-and-float test is not adapted to the treatment of these fine sizes. Evidently the fine dust is buoyed up so that it floats, or else it is entrained in floccules of clean coal. To test the hypothesis that possibly the fine coal was full of gas bubbles which gave it too low an apparent specific gravity, two tests were carried out by applying reduced pressure to the surface of the zinc chloride solution in which the finely ground coal was suspended. A similar test with zinc chloride solution of lower specific gravity than those shown in the table had given no float, so we found it necessary to use denser solutions. The data on these tests are given in Table III.

TABLE III—SINK-AND-FLOAT TESTS UNDER REDUCED PRESSURE ON DRY GROUND COAL (−200 MESH) SOAKED IN $ZnCl_2$ SOLUTION FOR 2 HOURS UNDER REDUCED PRESSURE

		Float			Sink	
Sp. Gr. of $ZnCl_2$	Pressure, Atm.	Weight, Per Cent	Ash, Per Cent	Recovery, Per Cent	Weight, Per Cent	Ash, Per Cent
1.37	0.1	7.7	10.48	8.90	92.3	23.77
1.48	0.1	87.8	16.98	93.20	12.5	55.80

While these tests failed to give us clean float products, they are quite interesting in that treating the coal under a reduced pressure evidently removed gases from the pores of the coal, so that its apparent specific gravity was increased. However, to assure ourselves, since the above tests had been run with dry-ground coal, we prepared a sample by wet grinding in a pebble mill, grinding till it all passed a 200-mesh sieve. This material was then subjected to sink-and-float tests in zinc chloride solutions of varying specific gravities, the data of which are given in Table IV.

TABLE IV—SINK-AND-FLOAT TESTS ON WET GROUND MATERIAL (−200 MESH)

		Float		Sink	
Sp. Gr. of $ZnCl_2$ Soln.	Pressure, Atm.	Weight, Per Cent	Ash, Per Cent	Weight, Per Cent	Ash, Per Cent
1.61	1.0	98.9	22.68	1.1	....
1.56	1.0	98.7	22.93	1.3	....
1.52	1.0	98.8	22.34	1.2	....
1.45	1.0	99.1	21.48	0.9	....
1.40	1.0	0.1		99.9	....
1.34	1.0	0.0		100.0	....
1.45	0.1	84.7	19.87	15.3	31.27

Under full atmospheric pressure this coal tended to all float or all sink, according to the specific gravity of the $ZnCl_2$ solution, and had an apparent specific gravity between 1.40 and 1.45. On treating a sample with 1.45 sp.gr. solution at one-tenth atmospheric pressure, in order if possible to remove the gas bubbles from some of the ash material and permit it to sink, there was a separation of high-ash material and the float coal was cleaner, but the separation was not clean.

We are not reporting all the various sink-and-float tests made by us, but the above illustrates the fact that this method of studying the ash in the coal is not applicable to the fine sizes and hence is not available for controlling the work in a froth flotation study.

Effect of Mesh on Gravity

The anomalous results obtained in this study can be explained by the following hypothesis: Coal is a porous substance with long cells, more or less resembling compressed charcoal. The true specific gravity of amorphous carbon has been determined by various experimenters to be about 1.88 and the apparent specific gravity of clean coal, 1.30, is evidently due to the porous nature of the coal, the pores being filled with moisture and gases. With the coarse lumps of coal ordinarily dealt with in the sink-and-float tests, the greater portion of the pores is buried and cannot be filled by the zinc chloride solution, even on long soaking or even boiling. Soaking is necessary to get consistent results even with coarse coal due to the necessity of displacing all easily displaced air in pores that are open to the outside. Boiling temperatures during soaking also assist in getting the samples properly saturated with solution. When fine sizes of coal are treated by the sink-and-float test, a much greater proportion of the pores is open to the outside and hence, by applying reduced pressure during the application of the test, it is possible to displace a greater proportion of the gases from the pores and substitute zinc chloride solution in these pores. This results in an increased apparent specific gravity. In the case of the Wilkeson coal the increase was from 1.34 for coal in lumps coarser than 100 mesh to approximately 1.43 when it was reground to pass a 200-mesh screen.

Froth Flotation Tests of Slimed Coal

Due to uncertainty of previous work on slimed coal we felt it best to repeat some of the work, particularly a series of tests with different types of flotation oils, to see if we could find one that had more marked selective properties. Not a great deal of true slime is formed in breaking the coal for coal washing, but that which is formed is thrown away. We therefore decided that if suitable conditions could be found for flotation of clean coal the work would be justified.

The sample tested was ground very fine in a porcelain pebble mill to pass a 200-mesh screen. It was stored in a tub under water and for each test the pulp was stirred up and approximately the same volume dipped into the flotation test machine.

The machine used was the Ruth junior laboratory machine. It was run at a constant speed of 1,200 r.p.m. and the aëration varied by restricting the air that went down the hollow spindle. Seattle city water was used in all tests. This water is very pure, being frequently used in place of distilled water for filling storage batteries. The pulp dilution was varied from 1:9 to 1:15. When flotation oil was added, the opening in the spindle was closed to prevent formation of a froth until the oil had been well stirred into the pulp. Tests were carried out slowly, adding a small quantity of oil at a time, as it was thought previous work had suffered from overoiling of the pulp. The concentrate was removed in three portions to ascertain if there was any variation in the flotability of different constituents of

the coal. The last concentrate was taken off 30 minutes to 1 hour after beginning the test, and flotation was continued till no more froth would form. The residual pulp in the machine was of a chocolate color and analysis showed that it was usually nearly all ash.

The data on these tests are contained in Table V.

In this table are given the amount of oil used in making each concentrate, the percentage of ash in the concentrate and the recovery of pure coal or combustible matter. In the columns dealing with the second concentrate are also given the cumulative recovery of combustible (concentrates Nos. 1 and 2 together) and the average percentage of ash in the first two concentrates. Similar figures are given for the third concentrate.

Appearance of the Froth

The first froth was of a brown color, while the last one was very black. We expected that the brown froth would contain a high percentage of ash, but found that it was the cleanest. The brown color was evidently due to greater subdivision of the coal. Since screen analyses could not be made on this very fine material, we had to be content with microscopic examination. We were able to see qualitatively that the first froth contained much very fine ground coal and the last froth was the coarsest coal. This might have been expected, as it is well known that the finer sizes of other minerals are likewise the most easily floated.

In fact, the fine sizes could be floated from the pulp to some extent without the addition of any oil. A froth made in this manner contained 9.5 per cent of ash. If too much oil was added at any time, a very bulky froth formed quickly and overflowed all sides of the machine. On that account the oil should be very well mixed into the pulp before any froth is permitted to form.

Oils

Referring to the tables, it will be seen that the best results were obtained with a mixture of six parts of alpha-naphthylamine, usually known as X-cake, and 4 parts xylidine, as it produced the cleanest concentrate and a high percentage of recovery. A mixture of one part xylidine with four parts Calol D4 (a petroleum distillate) also gave good results. Pine oil, aqueous solutions of phenol and hardwood creosote were not good oils, as they gave a very dirty concentrate. In general, rather thin fluid oils seemed to work best. The consumption of the various oils varied from 0.42 to 1.11 lb. per ton of coal.

Discussion of Tests

By referring to test 3, the one with xylidine-X-cake mixture, it can be seen that the total recovery is 97.7 per cent in the form of a concentrate containing 13.22 per cent ash. This result is far better than would be expected from other tests. The first and second concentrates contained 11.15 and 11.79 per cent ash respectively, but the third concentrate contained 24.5 per cent ash. The same general condition is true in the other tests. This suggested that the third concentrate ought not to be combined with the two others but ought to be regarded as a middling product and re-treated. Consequently all the middlings from the first sixteen tests were combined to give enough feed for a re-treatment test. This is test No. 17. Its feed averaged 29.3 per cent ash and it gave a concentrate averaging 20.30 per cent ash with a 95.6 per cent recovery of combustible.

This seemed to indicate that the coal was very easily floated but that clean flotation in one operation was difficult. Re-treatment of all the various products seemed to be in order, and this procedure was later carried out.

Flotation of Coarser Coal

Previous work by A. P. Wichmann indicated that better flotation could be obtained with 35-mesh material, so another lot of coal was crushed dry to pass a 35-mesh sieve. This was part of the sample that had been used in the sink-and-float test. The same machine

was used for testing, but the pulp density was 7:1 and the duration of the test was shortened to 10 minutes.

Effect of Size of Particle

The first tests with this material were on different sizes removed from the crushed sample by screening. The data on these tests are contained in Table VI.

In the tests it was noticed that the finer sizes of coal floated much more easily than the coarser. In test 24 the froth which formed without the addition of any oil was collected as the first half of the first concentrate and was found to contain 9.35 per cent ash and the recovery was 27.6 per cent of the total clean coal. The material used for this test passed a 100-mesh screen and was retained on a 200-mesh screen.

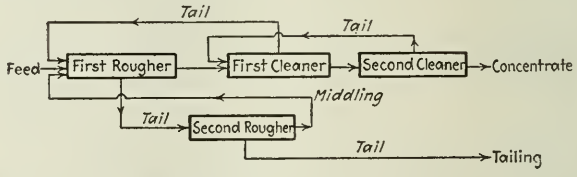
With the exception of the slimed material which passed a 200-mesh screen, the finer the size of material the cleaner the concentrate, other conditions being equal. Evidently the slimed coal is detrimental to the obtaining of clean concentrate. The first concentrate contained only 8 to 10 per cent ash in all the tests, and this suggested that either it was the cleanest coal which floated first or the later froths should be regarded as middling and re-treated.

Again the xylidine-X-cake mixture showed itself superior to other oils in obtaining clean concentrate even with coarse material.

Repeated Froth Flotation

Based on the inferences gained from the above work, we then carried out three series of tests according to definite flow sheets, in which both the tailing and the concentrate of the rougher cell were re-treated and middling returned for re-treatment. The Ruth machine was used and various fractions of the coal from these tests were set aside, each to take its turn in following out the flow sheet, since each operation mentioned in the flow sheet had to be done in the one machine. The water was re-used in each test in order to recover as much of the flotation oil as possible. The complete set of operations in following out such a flow sheet was called a "locked test."

As seen in flow sheet No. 1, the concentrate from the first rougher cell was cleaned and then recleaned, middling from each operation being returned to the next machine ahead. The tailing from the first rougher was treated in a second rougher to recover any coal not floated in the first rougher and return it to the main feed. The coal for this test was crushed dry to pass a 65-mesh screen and the first roughing took place at a pulp dilution of about 1:7. The oil used was the X-cake-xylidine mixture previously found most effective. This locked test involved twenty individual flotation operations on eight samples of coal. The results are summarized in Table VII. A screen analysis was made on the feed and on the concentrate and these analyses are included in the table.



FLOW SHEET OF LOCKED TEST NO. 1

It was disappointing to find such a high percentage of ash in the final concentrate and also to find that the intermediate products all through the system which were being returned for further treatment were so high in ash as to be almost capable of going into the tailing. The original coal contained 23.42 per cent ash and the concentrate of this series of tests contained 17.10 per cent ash, with a recovery of 95.5 per cent of the pure coal. Evidently this is the wrong flow sheet. High oil consumption suggested overoiling and consequent dirty concentrate. It was also thought that too

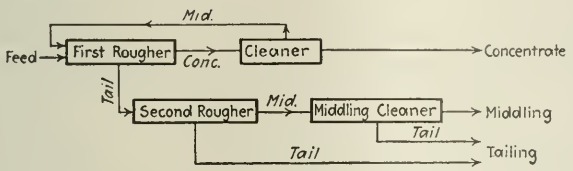
much slime was present in the pulp and that coarser crushing would be beneficial. The screen analysis of the concentrate showed more ash in the finer sizes.

Following out this idea, we ran a second series of tests with material crushed to pass only a 20-mesh sieve, following the same flow sheet. Crude wood turpentine was used as an oil, and we were careful to avoid over-oiling. This test, as compared with the first one, involved changing three variables, but these "locked" tests involved so much labor that we thought it best to reason out the best set of conditions as indicated by previous tests and try them immediately rather than to carry out laboriously a whole series of tests, changing only one variable at a time.

The results of this second series of tests are summarized in Table VIII.



FLOW SHEET OF LOCKED TEST NO. 2

The concentrate in this case contained 15.41 per cent ash and a recovery of 91.5 per cent of the pure coal was made. Again the intermediate products were too low grade and showed that they should not be combined with the feed in the way that they were. The concentrate has probably been considerably contaminated by the return of these high-ash products. The ash content of the various sizes in the concentrate seemed to increase distinctly with decrease in size. The screen analyses also show that a good deal of coal is further broken up during the flotation, possibly due to the action of the Ruth impeller.

From these results it seemed best to use a flow sheet in which complete flotation of everything from each cell would leave a tailing which could be discarded immediately. Flow sheet No. 2 meets this condition.

The coal was dry crushed to pass a 20-mesh screen and the head sample contained 23.51 per cent ash. Other tests on this size of material indicated that the concentrate would contain 20 per cent ash if over a 95 per cent combustible recovery was attempted. Screen analyses were made of the feed, concentrate, middling and tailing. The X-cake-xylidine mixture, with sufficient lime water to impart distinct alkalinity to the pulp, was used. All water from the tailing and concentrate was recovered and used in order to economize on oil. The data on this locked test are contained in Table IX. No attempt was made to float all the coal in the first rougher.

This method of operating gave more favorable results, although a much larger middling product was produced. We concluded that the coal must contain particles of various ash contents varying from the almost pure coal, through bony coal, bone and bituminous shale to pure shale or ash. If this be true, and the sink-and-float work seems to bear this out, a flow sheet should be adopted which divides the coal into clean concentrate and bony middling as was done in this test. The concentrate contained only 10.76 per cent ash with a recovery of 63.68 per cent of the pure coal and if the middling is included with the concentrate the ash analysis would be 15.07 per cent with an extraction of 88.88 per cent. The oil consumption was 2.26 lb. per ton of coal.

The screen analyses show that some pulverization of the coal took place in the flotation machine. Also the cleanest sizes were those passing a 35-mesh screen and staying on a 100-mesh screen. The sizes coarser than this are presumably not crushed sufficiently to liberate the ash, while the sizes finer than this are difficult to float clean.

Discussion of Results

In all our tests it was noticed that the first material to float was the very finely divided material and that it required almost no oil for its flotation. When oil was added in any quantity this fine material was "over-oiled" and tended to float in too dirty a concentrate. Microscopic examination did not show differences in appearance between the clean coal and the bone, so we had to rely entirely on the chemical analyses of the various products which we made. However, we formed the idea that the only way to combat the tendency of fine bone coal to float with coarse pure coal is to either deslime the feed and treat the two products separately by flotation, or else treat the various rougher products repeatedly in order further to differentiate them. We chose the latter as the most practical proposal.

We have not been able to prove to ourselves beyond

TABLE IX—SUMMARY OF LOCKED TEST NO. 3

Concentrate				Middling					Tailing		
Weight, Per Cent	Ash, Per Cent	Oil, Lb. Per Ton	Recovery, Per Cent	Weight, Per Cent	Ash, Per Cent	Cumulative Amount of Oil, Lb. Per Ton	Cumulative Per Cent Recovery Pure Coal	Average Ash, Per Cent	Weight, Per Cent	Ash, Per Cent	Per Cent Elimination of Ash
54.5	10.76	0.95	63.68	25.4	24.35	1.49	88.88	15.07	20.1	57.80	49.1

Screen-Analyses of Feed and Products (Moisture-Free Basis)

Screen	Feed—20 mesh Weight, Per Cent	Feed—20 mesh Ash, Per Cent	Concentrate Weight, Per Cent	Concentrate Ash, Per Cent	Middling Weight, Per Cent	Middling Ash, Per Cent	Tailing Weight, Per Cent	Tailing Ash, Per Cent
On 28	5.38	28.27	0.10	13.54	0.10	19.29	0.11	54.70
On 35	22.34	26.70	8.42	10.18	17.32	20.74	17.66	46.07
On 48	18.83	25.12	14.63	8.42	29.03	23.80	12.63	50.60
On 65	15.07	23.60	16.53	8.13	18.52	23.53	19.81	56.40
On 100	11.07	23.85	15.63	9.59	14.51	23.16	16.91	60.85
On 200	14.68	23.52	32.47	12.85	10.81	31.72	21.88	69.80
Through 200	12.63	23.33	12.22	13.56	9.71	37.75	11.00	75.20
Total	100.00	24.87	100.00	10.77	100.00	25.25	100.00	59.57

all shadow of a doubt that the finely ground coal is actually made up of particles of varying specific gravity and of varying ash content, but all data point that way, and if true, our third locked test has come very near the limit in possibility of separation, since the cleanest product shown in the sink-and-float tests contained about 8 per cent ash and the concentrate in our third locked test contained only 10.76 per cent ash. The middling product or bone from this test would probably have to be marketed as such, separately from the clean coal.

Conclusions

1. Tests on a bony coking coal from the Wilkeson mine, at Wilkeson, Wash., have shown that the cleanest coal can be floated first, the bony coal next and the ash last by ordinary froth flotation.

2. Very thin oils or soluble frothing agents work best.

3. The fine sizes of coal float the most easily and the coal in the very fine slime will float to some extent without the use of any flotation oil whatever.

4. Due to the tendency of fine sizes to float so easily, they are probably "overoiled" and produce dirty concentrate when enough oil is added to float the coarser sizes. Screen analyses of the flotation concentrate show increasing percentages of ash in the finer sizes.

5. To take due advantage of the above facts it is necessary to use a flow sheet in which roughing treatment is followed by cleaning of both concentrate and tailing from the roughing cell, discarding as tailing material which will not float in any of the re-treating cells. Re-treatment of middling with original feed is not desirable except for the middling obtained in cleaning the rough concentrate.

6. By this method of treatment a clean concentrate can be obtained, the bony portion of the coal forms a middling which may have a market value, and the tailing is too low in coal to be of any value.

7. Attempts to control the flotation tests by sink-and-float tests with heavy solutions have failed on the fine sizes of coal due to their supposed porosity.

Lead Pigments Marketed in the United States in 1920 and 1921

The following table shows the quantity and value of lead pigments marketed in the United States in 1920 and 1921 as reported by producers to the United States Geological Survey.

LEAD PIGMENTS MARKETED IN THE UNITED STATES, 1920 AND 1921

	1920			1921		
	Short Tons	Value Total	Per Ton	Short Tons	Value Total	Per Ton
Sublimed Lead:*						
White	12,412	$2,083,647	$167.87	11,568	$1,418,403	$122.61
Blue	928	153,657	165.58	463	58,593	126.55
Red lead	21,814	3,410,904	156.36			
Orange mineral	34,431	7,523,089	218.50	379	91,184	240.59
Litharge	62,329	12,386,185	198.72	41,953	5,740,690	136.84
White lead:						
Dry	33,678	6,351,798	188.60	26,695	3,749,851	140.47
In oil	112,017	25,986,100	231.98	143,634	27,713,257	192.94

*Includes basic sulphate lead.

A decrease is shown in the sales of each of these pigments in 1921 as compared with 1920 with the exception of white lead in oil, in which an advance of 28 per cent was made. A decrease is also shown in the average price per ton of each product in 1921 as compared with 1920.

Recent Developments in Low-Temperature Coal Carbonization

AT A RECENT symposium on the low-temperature carbonization of coal held in Cardiff, South Wales, a number of papers were read bearing on the various processes that are being developed in Great Britain at the present time. This subject has aroused considerable interest in Great Britain, as it holds promise of utilizing the non-coking coals and fine slack and dust—a possibility of some economic importance to the country. Several items of interest were brought out during the meeting in connection with recent experimental and development work.

Critical Temperatures of Carbonization

N. H. Freeman gave some interesting facts with regard to what may be called the "critical temperatures" of various stages in the carbonization of coal, and suggested that the essential dividing line between high- and low-temperature carbonization should be taken as 800 deg. F., this being the temperature at which the complex hydrocarbons of the coal substance begin to decompose, forming free carbon and free hydrogen. It was pointed out that the first stage in the carbonization of coal is the separation of water (together with occluded gases), which begins at 212 deg. F. and continues to 500 deg. F. Another critical stage for average coals begins at about 450 deg. F. and may continue to as high as 650 deg. F. In this stage a great portion of the coal substance is transformed into a more or less soluble or semi-soluble condition, and it is only when this stage is completed that oil begins to separate. The oil begins to distill immediately afterward, within a comparatively short range of temperature, up to say 800 deg. F., depending on the constitution of the coal. After this maximum temperature the products coming over are tars, pitches, phenols, anthracenes, etc., the process being then in the nature of high-temperature carbonization. According to Mr. Freeman, coal—because of its low heat conductivity—can be submitted efficiently to low-temperature carbonization only when it is finely divided, in thin layers, and constantly agitated so that every particle is subjected to the same temperature, which must be automatically controlled at the different stages.

Low-Temperature Carbonization Applied to the Mond Process

Some new and interesting information is contained in the paper submitted by the Power Gas Corporation, Ltd., which company has been using the Mond process for the past 30 years. In the original Mond process it was possible, using cheap slack containing 1.3 per cent nitrogen, to recover ammonia to the extent of 65 to 75 per cent of the total nitrogen, equal to 85 to 95 lb. of sulphate of ammonia per ton of coal, with a yield of gas of 135,000 cu.ft. It was necessary, however, to add to the producer a very large amount of steam, about 2½ tons per ton of coal, one-third of this steam being decomposed in the producer, and two-thirds passing away in the gas, which left the producer at about 925 deg. F. About ¾ lb. of the steam is recovered, however, so that a net amount of 1¾ lb. of steam per pound of coal is required. Today this process has no longer the great economic advantages in Great Britain it formerly had, because the price of

labor, coal and sulphuric acid has increased out of all proportion to that of the sulphate of ammonia.

Consequently the Power Gas Corporation, Ltd., has now altered the original Mond process with a view to increasing both the economy and the efficiency, and now combines with it the principle of low-temperature carbonization. This new process, that of Beswick and Rambush, consists in converting as much as possible of the volatile matter of the coal into liquid products according to low-temperature methods, while the residual fuel is entirely converted into producer gas. The transmission of heat to the charge of raw coal in the upper part of the producer is claimed to be achieved in a gradual but effective and rapid manner by the employment of the sensible heat contained in the hot producer gas evolved in the lower part of the producer. That is to say, the raw coal charged into the producer is kept in the upper or primary zone at such a temperature as to get a low-temperature carbonization with the maximum yield of oils, and the residual fuel is then converted into producer gas in the lower or secondary zone. At the same time the very high yield of sulphate of ammonia, 90 lb. per ton of coal, characteristic of the original Mond process is retained, and the whole operation is carried out in one simple plant which is comparatively cheap to erect. The steam required in this new process is only about 1 lb. per pound of coal carbonized. Also, nearly all this steam is decomposed, and the saturated air blast no longer requires to be superheated. The gas evolved has an average composition of 21.0 per cent CO, 20.5 per cent H_2, 8.3 per cent CO_2, 4.9 per cent CH_4, and 45.3 per cent N_2, with a net calorific value of 178 B.t.u. per cu.ft. The yield of gas is 115,000 to 120,000 cu.ft. per ton, and the quality is very nearly as good as the ordinary hot producer gas. The amount of low-temperature tar or oil produced is about 15 to 24 gal. per ton.

Additional advantages claimed for the new process are that, because of the lower temperature in the producer, the pipe lines are smaller, the maintenance costs are reduced and the capital outlay and ground space are both much less because of the elimination of the air and steam superheaters. Also the plant is so arranged that the amount of either tar or ammonia can be easily manipulated, depending on the market.

The Maclaurin Continuous Retort

The method of internal carbonization is particularly characteristic of the "Maclaurin" process, which, in fact, differs from all others in having no external heating at all, not even steam. The continuous retort used resembles an elongated producer or small blast furnace, the height being about 40 ft. and the width at the combustion zone about 8 ft. The raw coal is charged in at the top and passes slowly down the retort, the residual fuel being withdrawn at the bottom. The carbonization is carried out by the heat produced by the combustion of a portion of the charge in the lower part of the retort. The hot products of combustion pass upward, gradually heating the coal in the upper layers, and carrying with them the volatile products given off, which are then condensed by the charge of cold coal entering the top of the retort, the oil and other products being separated by patent oil traps so that they do not trickle back into the hotter regions. The period of carbonization is 20 hours, and it is stated that any size of coal can be used up to pieces that will pass through the bell, which is 8 to 9 in. in diameter.

The residual smokeless fuel in the ordinary method of working has been formed at a temperature of about 1,300 deg. F. and contains about 4 per cent volatile matter. It is black in color and is easily ignited like ordinary coal. The heat losses of the process are said to be small, being confined to the radiation from the plant, the heat lost in the hot coke and the gases leaving the producer.

The oil is of peculiar composition, being similar to low-temperature oil in that it has no naphthalenes and anthracenes, but differs in having no light oils, although there is present a very high percentage of cresols and xylenols, up to 50 per cent of the total oil, and including an exceptional amount of high-boiling phenols. The crude oil can also be used direct as fuel oil.

The composition of the gas is 16.0 per cent CO, 13.0 per cent CH_4, 16.1 per cent H_2, 6.2 per cent CO_2, and 48.1 per cent N_2. No hydrocarbons except methane are present, because the oils are not "cracked" during the process of carbonization. The yield of sulphate of ammonia is 24 lb. per ton, the ammonia liquors being free from ferrocyanides and sulphocyanides, but containing di- and tri-hydroxy phenols.

The further yield by this process from 1 ton of coal (12,300 B.t.u.) with 35 per cent volatile matter and 7.7 per cent water, is 1,096 lb. of residual smokeless fuel, 15.6 gal. of oil and 27,731 cu.ft. of gas at 247 B.t.u., the total loss in the whole process being 11.3 per cent of the coal. It must be pointed out, of course, that in comparison with other processes these figures must be increased by about 15 per cent, since no external producer gas is required.

Pure Coal Briquets

The free-burning properties of low-temperature fuel depend to a considerable extent on the structure of the fuel as well as on the proportion of volatile matter. In discussing the merits of low- and high-temperature carbonization for the production of smokeless fuel, Edgar C. Evans brought out the importance of this consideration, stating that coals which contain little resinic matter and do not fuse or swell during carbonization always give a free-burning coke, because such coke is of quite different structure from the sponge-like substance of ordinary gas or furnace coke, the pores being very much smaller and the whole structure much more granular. Also, this free-burning coke is not impregnated with a film of graphite, which covers ordinary coke and renders it so incombustible.

The "pure coal briquet" (Sutcliffe-Evans) process consists in roughly pulverizing the coal and mixing it with about 20 per cent of pulverized coke breeze or other product from the carbonization of coal. This mixture is then briquetted in a special briquet press at a very high pressure, 10 tons to the square inch, giving perfectly hard briquets without the use of a binder such as pitch. These briquets are now carbonized by means of producer gas at high temperatures, say 1,600 deg. F., the heated inert gas passing through the mass of the briquets in a simple type of retort which is merely a vertical cylinder. These briquets have the remarkable property that they do not expand on carbonizing, so that existing gas-works or coke-oven retorts can be used. Also, although the residual fuel contains only about 2 per cent of volatile matter, it is easily ignited like ordinary raw coal, because of the peculiar fine grain structure which, under the microscope, is seen to resemble charcoal.

Committee Recommends Acceptance of Ford Offer —Inclusion of Gorgas Plant Only Disagreement

Consideration of the disposal of the Muscle Shoals property of the government has been transferred from the Committee on Military Affairs to the House of Representatives proper. A majority of the members of the Military Affairs Committee recommends the acceptance of the Ford offer with the elimination of the steam plant at Gorgas and of the transmission lines connecting it with the No. 2 nitrate plant. The majority also insists on a rewording of the fertilizer guarantee and other amendments of less importance. A minority of the committee will recommend the acceptance of the offer as finally amended on May 31 by Mr. Ford. Every effort will be made to obtain prompt consideration of the matter on the floor of the House.

Revised Fertilizer Provisions

The new fertilizer clause, upon which a majority of the committee insists, reads as follows:

> Since the manufacture, sale and distribution of commercial fertilizer to farmers and other users thereof constitute one of the principal considerations of this offer, the company expressly agrees that, continuously throughout the lease period, except as it may be prevented by reconstruction of the plant itself, or by war, strike, accident, fires or other causes beyond its control, it will manufacture nitrogen and other commercial fertilizers, mixed or unmixed, and with or without filler, according to demand, at Nitrate Plant No. 2 or its equivalent, or at such other plant or plants, adjacent or near thereto as it may construct, using the most economical source of power available. The annual production of these fertilizers shall have a nitrogen content of at least 40,000 tons of fixed nitrogen, which is the present annual capacity of Nitrate Plant No. 2. If during the lease period said Nitrate Plant No. 2 is destroyed or damaged from any cause the company agrees to restore such plant, within a reasonable time, to its former capacity.

Ford Insists on Inclusion of Gorgas Plant

W. B. Mayo, representative of the Detroit manufacturer, declared that he regarded the action of the committee as a decisive victory for Mr. Ford and that a more determined effort than ever before would be made to obtain the properties. He felt that agreement on all points but one—the Gorgas plant—was a distinct achievement.

That Mr. Ford is anxious to have the Gorgas steam plant included in the terms of the lease is evident from a letter which he addressed to the Military Affairs Committee, just prior to the action of that body. He declared in this letter that he would not consider taking over the property unless the Gorgas plant is included. The full text of the letter is as follows:

> I have carefully examined the amendments made by your committee to my proposal dated Jan. 25, 1922, for the lease and purchase of the government's Muscle Shoals properties, and observe with surprise and regret that you have rejected that part of the modified proposal relating to the government's Gorgas steam plant.
>
> The greater portion of the other changes suggested by your committee have been approved and are incorporated in the accompanying corrected proposal. More than a month ago Mr. Mayo presented to me certain clarifications in the proposal of Jan. 25 to which your committee desired my agreement, which was promptly given. Mr. Mayo explained that while some of your committee were unwilling to accept that part of my offer which included the government steam plant at Gorgas, certain other members of the committee had requested him to ascertain if I would agree to accept an assignment and transfer by the United States of everything now owned by the government at Gorgas under its contract of Dec. 1, 1917, with the Alabama Power Co., to which I assented, and Mr. Mayo was instructed to advise your committee that the offer would be revised accordingly. I have been informed that this revision was accepted by your committee, but later, upon reconsideration, you decided to eliminate the Gorgas plant.
>
> I cannot consent to eliminate the Gorgas plant, because it is necessary to the economical operation of the Muscle Shoals properties. If my revised offer for Gorgas is rejected, then I must understand that the acceptance of my offer for Muscle Shoals "as a whole and not in part" is refused.
>
> I am sending a final proposal containing all the amendments suggested by the committee to which I can consistently agree. In doing so, and in view of the fact that my first proposal was signed July 8, 1921, *nearly a year ago*, and in order to bring these negotiations to a close, I ask that your committee consider this proposal as final, and that no further changes should be expected. I further request that your committee send this final offer to the House so that its members may vote for acceptance or rejection. This request is made with the understanding that power to dispose of the plants at Muscle Shoals is vested in the Congress. If the Secretary of War after his negotiations relative to the first offer did not have the power to accept or reject it, you will probably agree that your committee has not the power to accept or reject it. Moreover, I do not believe that your committee or any member of it wishes to assume the responsibility of accepting or rejecting this final proposal, involving as it does a matter of such great national importance.
>
> If Congress votes acceptance of my offer, we will get on the job at Muscle Shoals at once; but if Congress rejects it, that will be but the beginning of a more determined effort on my part to save Muscle Shoals for the benefit of the public.
>
> I wish to thank you and each member of the committee for the courtesies shown my representatives during the negotiations of the past three months.

Appropriation for Completion of Dam Approved

Another important development in Congress affecting Muscle Shoals while the committee was in session was the adoption in the Senate of an amendment to the War Department appropriation bill proposed by Senator Norris, on behalf of the Senate Agricultural Committee, appropriating $7,500,000 for continuing work on Dam No. 2. Senator Norris stated that it would take 3 years to complete the dam and develop power there and that the project would cost about $22,500,000. The War Department appropriation bill with the Muscle Shoals appropriation was passed by the Senate and will go to a conference with the House, which has already passed the bill.

Will Not Interfere With Lease Proposals

In the discussion of the amendment, Senator Jones of Washington asked what effect the amendment would have on the lease proposal of Henry Ford. Senator Norris replied that the construction of the dam would not interfere with any of the lease proposals before the committee and about which there was difference of opinion. Senator Lenroot of Wisconsin stated that he had previously opposed completion of the dam on the ground that the Alabama Power Co. would be the only customer for the power. He is now inclined to favor the construction of the dam, however, as the situation has changed and if the dam is completed he thinks there will be no difficulty in securing a fair price for power, as there will be sufficient demand for it.

Final Program for Niagara Falls Meeting of American Institute of Chemical Engineers

The final program for the fourteenth semi-annual meeting of the American Institute of Chemical Engineers at Niagara Falls, Canada, June 19 to 21, has been distributed to members. The features are arranged exactly as published in CHEM. & MET. of May 3, with the exception of a few additional papers not announced at that time.

Clifford D. Carpenter and Joseph Babor will present a paper at the acid symposium on "Concentrating Dilute Nitric Acid Solutions." S. L. Tyler will discuss the "Absorption of Hydrochloric Acid or Other Gases." The Production of Hydrochloric Acid From Chlorine and Hydrogen" is the subject of a newly scheduled paper by H. K. Moore.

Problems in transportation of acids and corrosive chemicals will receive the attention of the meeting at the Thursday morning session. Contributions to this symposium will be made by J. M. Rowland, who will discuss the transportation of hydrochloric acid in tank cars, and F. C. Zeisberg, who will describe and discuss the "Hard Rubber-Lined Steel Tanks for the Transportation of Hydrochloric Acid." Another paper of interest on this general topic has been prepared by J. L. K. Snyder and H. P. Wells entitled "Transportation of Liquid Chlorine in 15-Ton Tank Cars."

In addition to the strong technical program, arrangements have been made for very delightful entertainment features, particularly for the visiting ladies. Automobile trips, luncheons, teas, theater parties and sightseeing trips will occupy their time during the technical sessions.

Industrial Advertisers in National Conference Will Discuss Marketing to Industries

As a new feature of the annual convention of the Associated Advertising Clubs of the World, which will be held in Milwaukee, Wis., June 11 to 15, a conference on Industrial Advertising is scheduled. It is proposed to make the Industrial Advertising Conference an annual affair, offering opportunity for the discussion of problems arising in connection with the marketing of goods to industry, as contrasted with the marketing of goods from industry to the individual consumer. Keith J. Evans, advertising manager Joseph T. Ryerson & Son, Chicago, is chairman of the conference.

Among the addresses scheduled for the first session, Monday afternoon, June 12 are the following:

"Advertising as a Factor in Interindustrial Marketing," by M. W. Babb, vice-president Allis-Chalmers Manufacturing Co.

"What the U. S. Department of Commerce Is Doing to Aid Interindustrial Marketing," by F. M. Feiker, vice-president of the McGraw-Hill Co. As personal assistant to Mr. Hoover for nine months, Mr. Feiker was engaged in reorganizing the three bureaus of the Department of Commerce which are designed to serve industry. He will describe the new purposes of the department in relation to interindustrial marketing and in addition will bring a personal message from Mr. Hoover to the Industrial Advertising Conference.

"Cutting the Costs of Distribution," by Sydney Anderson, Congressman from Minnesota.

"Advertising in Its Relation to the Four Points of Contact in Industry," by Bennett Chappel, director of publicity, American Rolling Mills.

On June 13 Charles H. Mackintosh, of La Salle Extension University, will talk on "Advertising the Technical Product to the Non-Technical Buyer." J. C. McQuiston, of the Westinghouse Co., will speak on "Selling to the Professional Man in Industry." Mr. McQuiston will discuss the influence of the architect, engineer, chemist and others who have a professional relationship to the buying of industrial products, which presents an important problem in the development of interindustrial markets. H. Colin Campbell, of the Portland Cement Association, will talk on "Expanding the Markets for Raw Materials," and W. Lee, vice-president of Frank D. Chase, Inc., on "Putting Ideas Into Industrial Advertising."

A large and complete exhibit of the best advertising in the country has always been a feature of the conventions of the Associated Advertising Club. This year there will be an exhibit of advertising showing effective methods of mass-selling to interindustrial markets in connection with the Industrial Advertising Conference. The McGraw-Hill Co., Inc., has offered a beautiful silver cup for the best complete campaign and a watch fob for the person who prepared it. Other companies are planning additional prizes which as yet cannot be announced.

Sales and advertising executives and all others interested in industrial marketing are cordially invited to attend the sessions of the Industrial Advertising Conference. It is unnecessary to be a member of any advertising club or organization.

National Fertilizer Association Program for Convention at White Sulphur Springs

The program of the twenty-ninth annual convention of the National Fertilizer Association, which will be held at the Greenbrier, White Sulphur Springs, W. Va., June 12 to 15, inclusive, has been completed. The business sessions promise to be of more than usual interest this year. Reports of standing committees will be presented, and subjects of current importance to the fertilizer industry will be discussed on the floor of the convention. In addition, M. Harcourt Paine and General O. K. Chance, both prominently indentified with the British fertilizer and chemical industries, will be present and address the convention.

The detailed program of the convention follows:

MONDAY, JUNE 12

10 a.m. Subscribers' meeting—Soil improvement committee of the National Fertilizer Association.

12 m.—Committee meeting—Soil improvement committee of the National Fertilizer Association.

3 p.m. Committee meeting—Southern soil improvement committee.

8 p.m.—Meeting of executive committee, Southern Fertilizer Association.

TUESDAY, JUNE 13

10 a.m.—Meeting of Southern Fertilizer Association.

2.30 p.m.—Golf, tennis and quoit tournaments.

4 p.m.—Tea dance at the clubhouse.

8.30 p.m.—Meeting of executive committee, the National Fertilizer Association.

9 p.m.—Informal dance.

WEDNESDAY, JUNE 14

10 a.m.—First business session, the National Fertilizer Association.

Address by Charles H. MacDowell, president of the National Fertilizer Association.

Reports of standing committees.

Address by M. Harcourt Paine, London, England, manager of the Chilean Nitrate Committee. Subject, "The Chilean Nitrate Industry and Its Propaganda."

Discussion of subjects of importance to the fertilizer industry.

12:30 p.m.—Official convention group photograph.

2 p.m.—Golf, tennis and quoit tournaments.

3 p.m.—Ladies' bridge tournament.

9 p.m.—Novelty convention dance.

THURSDAY, JUNE 15

10 a.m.—Second business session, the National Fertilizer Association.

Reports of committees.

Remarks by General O. K. Chance, London, England, first vice-president of the British Cyanides Co., Ltd.

Discussion of subjects of importance to the fertilizer industry.

Election of executive committee.

2.30 p.m.—Golf, tennis and quoit tournaments.

8 p.m.—Organization meeting of the new executive committee of the National Fertilizer Association.

9 p.m.—Informal dance and distribution of golf, tennis, quoit and bridge prizes.

First Section of Dye Tariff Schedule Adopted—Fight Expected on Finished Dyes and Embargo

The first test vote in the controversy over the protection of the American dye and organic chemical industries approved the committee amendments to the tariff bill after a 5-hour fight on the floor of the Senate. The approved amendment proposes a duty of 50 per cent ad valorem and 7 cents a pound on crude coal-tar dye products. The vote was 37 to 20, three Republicans opposing the amendment and one Democrat supporting it. The controversy over the 60 per cent and 7 cents a pound duties proposed on intermediates and the modified dye embargo provisions of the bill went over, as the Senate turned attention to a consideration of the brick schedule immediately after this one vote.

This action was regarded as a forecast of the approval of the other rates on finished dyes, but cannot be interpreted as any indication of what action will be taken on the embargo feature of the controversy. It is expected that action will not be taken on the embargo provision until it is reached in the administrative section of the bill.

King Voices Opposition

As expected, Senator King, armed with a mass of data and documents, opened an attack on both the rates and on the embargo. In a 5-hour speech he reviewed the dye situation, assailing the present control act which, he asserted, was passed during the war "as a result of misrepresentations by Dr. Herty and other propagandists and lobbyists of the dye interests." He asserted that the bill had gone further than the public or the Senate had foreseen when interpreted as covering all compounds of a synthetic organic nature. He assailed the embargo as un-American. "An embargo is not protection," he declared, "it is exclusion. It is the establishment by law of monopoly."

Returning to his disapproval of the rates on coal-tar products, Senator King declared that we are in a position to compete with the world in the production of crudes, intermediates and dyes, yet we are especially gracious to the coal-tar industry. He added that he would later call attention to the corporations, their ramifications, the immense amount of capital and the influence they command, which would profit by protective legislation.

Frelinghuysen Champions Protection

Senator Frelinghuysen, of New Jersey, answered by saying that even if we have the immense amount of coal referred to by the Utah Senator, the byproducts are of no value if intermediates and finished dyes are not protected. Lack of protection of these, he said, makes the products of the coke ovens valueless.

Senator Frelinghuysen in a very brief statement declared that the rates of 50 per cent on intermediates and 60 per cent on finished dyes, which are coupled with a 7-cent specific, are sufficient only to meet the difference in the cost of production here and some of the prices on imported dyes. He added that the Tariff Commission has declared that no ad valorem nor specific rate could be provided that would afford the protection needed by the industry.

The New Jersey Senator gave a brief history of the coal-tar industry. He stated that it is now in a position that makes the United States independent of the world as to dyes, but unless there is a restricted license which will permit the chemists to continue their research and experiments, the industry cannot live.

Expect Further Opposition From King

It is expected that Senator King will continue his fight for a reduction in the dyes tariff. It is probable that the Utah Senator will propose an amendment reducing the 7-cent specific duty to 3½ cents per pound on all dyes and intermediates selling at 10 cents a pound or less.

Another feature against which he is understood to be preparing an attack is that which calls upon the Secretary of the Treasury to prescribe standards of strength for dyes brought into the United States to be used as a basis for the levying of the specific rate of duty. He points out that certain dyes have come into the United States in 20 per cent strength, although perhaps the usual importations are of 60 per cent strength. Under the terms of the provision, he declares, it will be incumbent upon the Treasury Secretary to adopt the lower figures, whereupon the product of greater strength will have to pay triple rates by reason of being three times the strength of the minimum, or 21 cents per pound.

Chemical Glassware Rates Adopted

Considerable time was devoted to discussion of the rates on chemical, metallurgical and other glassware. Senator Frelinghuysen made an extended speech explaining the need for proper duties to protect the American industry from foreign competition, exhibiting samples of products of both foreign and American production. He spoke particularly of glassware used in the chemical industry. He declared that this glassware industry was one of the most important in the country, and read a letter from C. L. Parsons, secretary of the American Chemical Society, urging proper duties on glassware used in the chemical industry. Among the glassware samples submitted by the New Jersey Senator were some which he said cost 12 cents to manufacture in the United States, while the German product was selling in New York at 7.3 cents. A graduated cylinder costs 32 cents to manufacture in this country, while the German product sold for 17 cents in New York, he said.

That any effort to place chemical glassware on the free list is foredoomed to failure is indicated by the vote on an amendment by Senator Jones of New Mexico, attempting to reduce the duty from 75 to 45 per cent ad valorem, which was rejected by the decisive vote of 40 to 26.

Cyanide Put on Free List

For the first time since the tariff bill has been under discussion the Senate overrode the Finance Committee when it voted 46 to 14 to restore cyanide to the free list. Chairman McCumber of the Finance Committee, actively assisted by Senator Frelinghuysen of New Jersey, made a hard fight to hold in the bill 10 per cent ad valorem duty on "potassium cyanide, sodium cyanide, all cyanide salts and cyanide mixtures, combinations and compounds containing cyanide."

The amendment transferring cyanide from the dutiable schedule to the free list was introduced by Senator Oddie of Nevada, who contended that the gold-mining industry is entitled to free cyanide. Senator Frelinghuysen in opposing the amendment established beyond fear of contravention the fact that the officers and employees of the Roessler & Hasslacher Chemical Co. were entirely loyal throughout the war. Senator Sterling of South Dakota did not question the loyalty of the company during the war, but stated that, in addition to its being the only producer of cyanide in the United States, it has intimate connection with the interests which control cyanide production in Germany and in England.

Senator Pittman declared that, regardless of opinions one way or another about the Roessler & Hasslacher company, certain facts are uncontroverted. The control of the stock now is in the hands of the Alien Property Custodian; the company was organized by two men sent to the United States by the German syndicate; the company has had no competition in the manufacture of cyanide since its establishment in 1885; the concern always has been and now is the exclusive manufacturer of cyanide in this country; it is the sole distributor of imported cyanide; it "manufactures at this end of the line when it pays to manufacture here and sells here the German stuff when it pays better."

Chemical Porcelain and Stoneware

The 60 per cent ad valorem duty on chemical porcelain ware and chemical stoneware was adopted after amendments of Senator Jones of New Mexico to reduce the duty to 50 or 55 per cent were defeated.

Paragraph 47 was also adopted, covering 2½ cents a pound on magnesium carbonate precipitated; ½ cent a pound on chloride; ¾ cent a pound on oxide or calcined magnesia not suitable for medicinal use.

Technical Photographic and Microscopical Society to Meet at Luncheon, June 14

The first regular meeting of the Technical Photographic and Microscopical Society will be held in the Hotel Astor, New York, on June 14. Two previous meetings of representatives of various industries interested in the application of photography and microscopy to technology resulted in the organization of this society. Since its official organization, a great deal of interest has been evidenced by individuals and firms in varied branches of the chemical and allied industries. The membership already includes representatives of the following industries: paper, explosives, heavy chemicals, fertilizer, zinc, nickel, lead, leather and rubber.

An interesting program has been arranged for the meeting on June 14. Luncheon will be served at 1 p.m., after which several brief addresses are scheduled. Suggestions will be received from members and visitors as to the future policies and program of the society.

Federated American Engineering Societies Board Opposes Licensing of Mining Engineers

A council meeting, attended by all but one or two members, of the Federation of American Engineers was held in Pittsburgh, May 26 and 27.

One of the most important acts of the board was the adoption of the report of the committee on registration of engineers, of which Colonel Arthur S. Dwight of New York is chairman. The report as adopted contains the statement "that the reasons which justify the registration of engineers responsible for public work do not apply to mining engineers."

The general sentiment of the committee is summarized in the paragraph of the report which follows:

> The registration of licensing of engineers with consequent elimination from practice of all not registered. can be supported upon only two grounds:
> (*a*) The benefit of the profession.
> (*b*) The good of the public.
> Your committee has grave doubts whether licensing can benefit the profession enough to justify the cost and annoyance of the proposed measure. Further, your committee holds it should be beneath the dignity of engineers to fence themselves against qualified competition by the artificial barrier of a statute.

The committee recommends to the societies an expression of opinion that such legislation may properly cover engineers and architects charged with responsibility for public works. The committee agreed that the reasons which justify the registration of engineers responsible for public works do not apply to mining engineers, but was unable to agree as to the wisdom or unwisdom or registration of engineers engaged in other classes of work.

Other Timely Problems Discussed

The board announced plans proposing the solution of the national problems of water power and forestry, upon which "the industrial development of the nation and the standard of living of future generations largely depends." The resolution adopted by the executive board directs the council's committee on water power, of which Colonel J. H. Pinney of Washington is chairman, to place before President Harding the facts of the situation with regard to water power development in this country. The board's action at this time, it was stated, was prompted by "the federal Water Power Commission's lack of effective and permanent personnel."

Progress in a national survey of the two-shift day in American industries was reported by the council's committeee on work periods in continuous industries. This survey, called the most extensive of its kind ever made, has been in progress for more than a year, and purposes an exposition of industrial conditions which shall form a basis for establishing the relative merits of three shifts of eight hours each and two shifts of twelve hours each. Dr. H. E. Hower of the National Research Council, Washington, is chairman of the committee.

A report from the patents committee of the council, headed by Edwin J. Prindle of New York, voiced opposition to the Stanley and Ladd bills as detrimental to American invention and industry.

Reforestation, jurisdictional awards in labor, an International Engineering Congress, aërial research, engineering representation on the Civil Service Commission, foreign relations, waste in agriculture and plans for more intensive engineering organization, as proposed by Herbert Hoover, were other topics before the council.

Thirty societies are now supporting the federation, with individual members numbering about 60,000. The Canadian Institute of Engineers has taken steps to join, and much interest in the progress of the federation is being taken by societies on other continents.

Ambitious Program of Activities Outlined for Institute of American Meat Packers

Plans for the extension of the activities of the Institute of American Meat Packers have been submitted to its membership by the executive committee. The plans were drawn up by Thomas E. Wilson, president of the Institute, and are of interest to all technical and trade associations as an example of broad vision and scientific management in industry. At the next convention of the Institute the plans will be considered and steps taken to further their consummation, provided the members concur in their adoption.

Mr. Wilson summarizes his conception of the function of the Institute in the statement that he believes the Institute ultimately should become an organization which shall be a combined trade association, industrial museum, research institute and educational institution. Elaborating on this idea, he has outlined the scope of the Institute in each of its four functions.

As an Educational Institution

As an educational institution it should do at least three things:

1. Provide for specialized collegiate education for young men tending to enter the packing industry, just as the Colorado School of Mines provides training for young men expecting to begin their work in the mining industry.
2. Furnish special training to intermediate sub-executives of promise, already engaged in the industry.
3. Conduct a continuation school for plant employees and junior office help.

As a Research Institution

As a research institution it should:

1. Develop and systematize a body of scientific and technical data for the service of the whole industry.
2. Carry on agreed researches into new scientific and technical processes common to all packers without infringing on research along individual lines being done by specific companies.
3. Conduct experiments on the extension of products and reclamation of materials, except where experiments would infringe on orginal work done by some individual company.
4. Collate and disseminate information concerning discoveries and developments having relation to the packing industry without invading material developed by particular companies.
5. Conduct merchandising surveys and commercial research work.
6. Discover waste and study means of eliminating it.
7. Test material and equipment offered to the industry.

As a Trade Association and Industrial Museum

As a trade association it should continue to do what the Institute is now doing in this direction.

As an industrial museum it should provide space for permanent exhibits of models showing modern packing-house operation, specimens and processes, and it should rent out space for exhibits of materials of industrial value and for a permanent exhibit of packing-house machinery and supplies —a sort of scientific museum and centralized market place, a gigantic permanent show window, conveniently located where packers from all parts of the country may come and view samples before making purchases and installations.

Chemical Uses of Lime to Be Discussed by Convention of National Lime Association

The chemical industry will find matters of more than ordinary interest in the program for the forthcoming annual convention of the National Lime Association, which is to be held in Cleveland, Ohio, June 13 to 16. The first day of the technical sessions will be devoted to a symposium on lime for chemical industries, taking up the problems of chemical users of lime. Special consideration will be given to the alkali, glass, soda and sulphate paper pulp, soap and textile industries.

The final program for the convention has not been distributed, but it will be practically identical with the following advance schedule:

TUESDAY, JUNE 13

Joint meetings of staff, central office and regional bureaus.

WEDNESDAY, JUNE 14

10 a.m. Assembly and presidential address.

10: 30 a.m. "Lime Burning in Rotary Kilns," by Irving Warner.

Forum. Limekiln efficiency.

11: 30 a.m. Symposium on "Lime for Chemical Industries."

Papers:

"Alkali Industry," by R. C. Snowden, Hooker Electro Chemical Co.

"Glass Industry," by R. R. Shively, Monongahela Glass Co.

"Soda and Sulphate Paper Pulp Industry," by G. K. Spence, New York & Pennsylvania Paper Co.

"Soap Industry."

"Water Softening," by S. C. Hadden, Editor, *Municipal and County Engineering*."

"Textile Industry," by E. R. Darling, James Milliken University.

"Sulphite Paper Industry," by P. A. Paulson.

3: 30 p.m. "Observations on the Lime Industry in Europe," by John Kling and Colonel C. W. S. Cobb.

3: 45 p.m. "Mechanical Handling of Lime," by H. D. Pratt.

4: 30 p.m. "New Idea in Lime Barrels," by T. E. McNamara.

"What the Bureau of Mines Is Doing on Quarry Problems," by Oliver W. Bowles.

THURSDAY, JUNE 15

9: 30 a.m. Symposium. Lime in Construction.

11: 30 a.m. Lime in Agriculture.

Thursday afternoon will be devoted to a clambake and general good time on the lake shore.

FRIDAY, JUNE 16

9: 30 a.m. "Work of the Chemical Department," by M. E. Holmes.

10 a.m. "What I Have Found Out About Lime," by F. C. Mathers, professor of inorganic chemistry at the University of Indiana.

10: 45 a.m. "The Value of Research to Industrial Associations," by E. R. Weidlein.

11:30 a.m. "The Lime Association," by C. Warner.

12: 30 p.m. Some New Angles on the Use of Lime in Agriculture," by J. A. Slipher.

12: 45 p.m. "High Points in the Construction Department Program of Lime Promotion," by W. A. Freret.

2: 30 p.m. Business session.

Newton D. Baker, former Secretary of War, will address the members at the complimentary luncheon on Wednesday.

Senate Committee Raises C.W.S. Appropriation

An increase of $250,000 over the amount allowed by the House is given for general expenses of the Chemical Warfare Service next year by the Senate Appropriations Committee in reporting the War Department bill. An appropriation is also made of $262,000 for general construction at the Chemical Warfare Service station at Edgewood Arsenal.

Civil Service Openings for Chemists

The United States Civil Service Commission announces open competitive examinations for the following positions: Chemical engineer, $3,600 to $5,000 a year; associate chemical engineer, $2,500 to $3,600 a year; associate chemist, $2,500 to $3,600 a year; assistant chemist, $1,800 to $2,500 a year. Appointees at annual compensation of $2,500 or less may be allowed the increase granted by Congress of $20 a month.

Program Announced for Canadian Meeting of American Leather Chemists' Association

An ideal combination of business and vacation is offered the members of the American Leather Chemists' Association by the program for their ninetenth annual meeting. No more beautiful location could have been selected than Lake of Bays, Ontario, Canada, where the meeting will be held, and no more interesting topics to leather chemists could have been chosen than those which make up the program. The sessions will occupy all day Wednesday, June 21, and continue through Friday noon, leaving the weekend free for the visiting members to enjoy the natural attractions of the Lake of Bays region. The detailed program follows in part:

WEDNESDAY MORNING, JUNE 21

Committee reports on: "Determination of Moisture in Leather," "Determination of Epsom Salts in Leather," "Synthetic Tanning Materials."

"Influence of Atmospheric Humidity on the Strength and Stretch of Leather," by F. P. Veitch, R. W. Frey and L. R. Leinbach.

"Comparative Observations of the Tanning Properties of Vegetable Tanning Materials, Sorbanol, and Mixtures of the Two," by S. Kohn.

WEDNESDAY AFTERNOON

Committee report on the "Determination of Oils and Greases in Leather."

"Preservation Effect of Oils and Greases in Leather," by F. P. Veitch, R. W. Frey and L. R. Leinbach.

"Distribution of Grease in Leather," by L. Balderston.

"The Mode of Occurrence of Tanning in the Living Cell," by F. E. Floyd.

"The Bacteriology of the Fresh Steer Hide," by G. D. McLaughlin and G. E. Rockwell.

"A Layman in Research," by F. M. Moffat.

THURSDAY MORNING, JUNE 22

Committee reports on: "Rapid Washing of Chromed Hide Powder" and "Determination of the Water Soluble of Leather."

"Some Observations on the Histology of Bating Skins," by C. S. Hollander.

"Progress in the Physical Chemistry of Gelatine," by C. R. Smith.

"Non-Tannins," by F. H. Yocum.

THURSDAY AFTERNOON. TANNERS' SESSION

Committee report on the "Direct Measurement of the Plumping Power of Tan Liquors."

"Time Reduction in the Tanning Process," by R. O. Phillips.

"The Practice of Curing Heavy Hides," by G. D. McLaughlin and E. R. Theis.

"The Science of Curing Heavy Hides," by G. D. McLaughlin and E. R. Theis.

"The Versatility of a Plumping Method," by H. C. Reed.

"The Plumping Power of Acids," by J. S. Rodgers.

"The Importance of Finish in the Cutting and Marketing of Sole Leather," by H. B. Smith.

FRIDAY MORNING, JUNE 23

Committee reports on "Determination of Sugar in Leather," "Determination of Sugar in Extracts," "Comparative Analyisis," "Chrome Leather Analysis" and "Color Measurement of Vegetable Tanning Solutions."

"Modern Problems in Chrome Tanning," by D. Burton.

National Public Conference on Muscle Shoals Strongly Favors Acceptance of Ford Offer

The national conference of the Southern Commercial Congress, which held a three-day session at Muscle Shoals last week, is committed to fight to the end for the disposal of the government nitrate plants and waterpower projects to Henry Ford. The conference unanimously adopted memorials calling upon President Harding and Congress to end unprofitable delay in action on the Ford offer. According to Dr. Clarence J. Owens, director-general of the Southern Commercial Congress, "every resource and method at our disposal will be used to secure immediate action and disposal of this huge project of Henry Ford."

A committee on general information, empowered and instructed to "educate the American public on the national importance of the Muscle Shoals projects and the necessity of their immediate completion" was appointed during the convention. A legislative committee, empowered to further the program adopted at the conference, was also chosen.

The memorial to the President and Congress declares that the Muscle Shoals issue is national and not local, being of vital concern to the whole country. It is set forth that Mr. Ford's offer was the only one which provides for full development of all the power possibilities of the Tennessee River and for the utilizing of the natural resources of the Tennessee Valley, including the adequate improvement of navigation. It is declared that Ford was the only bidder for the projects who gave a guarantee of cheap fertilizers on a scale which offers substantial encouragement to millions of American farmers. Adoption of the memorial came unexpectedly at the final session of the conference, which was held in Tuscumbia, one of the three Muscle Shoals cities.

Hail Ford as Public Benefactor

Chester H. Gary of Missouri, chairman of the Muscle Shoals committee of the American Farm Bureau Federation, declared that Ford's proposed development of power sites along the Tennessee River would mean "a modernized and humanized agriculture." The American farmer is interested in Muscle Shoals primarily as a potential producer of fertilizer, he declared, "but agriculturists everywhere realize the possible advantages in opening the Tennessee River to navigation and in the application generally of electrochemistry to agriculture.

"Muscle Shoals means to the farmers of America cheaper farm machinery, cheaper transportation, cheaper automobiles and more conveniences for the womenfolk to be secured by the general use of electricity and aluminum."

Mr. Gary asserted that an example should be set at Muscle Shoals of what can be done with hydro-electricity "when applied to the common good," and predicted that other projects would follow in development.

In a message to the conference from Emmett O'Neal, president of the Muscle Shoals Association of Alabama, who was absent on account of illness, it was predicted that the "overpowering sentiment which now demands acceptance of the Ford offer will, with the weight of a mighty juggernaut, crush to powder any selfish corporation or individual who may attempt to check its triumphant march toward final victory."

Personal

J. Cavalier, president of the University of Toulouse, sailed for France, June 1, after concluding a series of lectures in America.

F. G. Cottrell, formerly director of the United States Bureau of Mines and until recently head of the division of chemistry and chemical technology of the National Research Council, has been selected for the directorship of the Fixed Nitrogen Research Laboratory of the Department of Agriculture. He will succeed Richard C. Tolman, who has resigned to become professor of physical chemistry and mathematical physics at the California Institute of Technology at Pasadena. No decision has been made as to the exact date on which Dr. Tolman will turn over the work to Dr. Cottrell. It probably will be late in the summer.

J. G. Detwilder, chief chemist of the Texas Co., Houston, Tex., gave an interesting lecture on the "Manufacture of Lubricating Oils" before the members of the lectureship course at the Agricultural and Mechanical College of Texas, College Station, May 19, forming the last of a series of instructive addresses, conducted under the auspices of the Mid-Continent Oil and Gas Association.

C. R. Downs, chief chemist of The Barrett Company's research laboratory at Edgewater, N. J., will take up work at Buffalo, N. Y., in the near future, for the National Aniline & Chemical Co.

A. A. French, Forest City, Ark., temporary vice-president and state vice-president from Arkansas of the National Oil Mill Superintendents' Association, was elected president of the organization by a unanimous vote at the twenty-ninth annual convention at Dallas, Tex., recently closed. D. B. Denny, Greenville, Tex., retires as president, after having served in such capacity for two years past.

Bennett Grotta, of the Atlas Powder Co. research staff at Emporium, Pa., is to make a tour of the company's Western plants this month.

Ellwood Hendrick, consulting editor of Chem. & Met., will sail on June 10 on the Royal Main Steamer Oripesa, arriving at Southampton June 19. He will attend the meeting of the Society of Chemical Industry in Glasgow early in July and will spend several weeks in England and Scotland, returning to the United States in August.

John S. Lowman, first vice-president of the Philadelphia Rubber Works, Philadelphia, Pa., is making a tour through Europe, including France, Italy and Germany. He is expected to return late in the present month.

F. F. Renwick has been appointed director of the Redpath Laboratory of E. I. du Pont de Nemours & Co. Mr. Renwick arrived from England last month to take charge of the work on photographic emulsions.

Howard M. Raymond has been appointed president of Armour Institute of Technology. Dr. Raymond has been dean of engineering since 1903 and acting president since the death of Dr. Frank W. Gunsaulus.

John T. Wood, East Liverpool, Ohio, has been elected president of the National Brotherhood of Operative Potters, as a result of a referendum election of officers of the association, in which 8,000 potters throughout the United States and Canada participated.

Obituary

Noah Bryant, one of the founders of the Bryant Paper Co., Kalamazoo, Mich., and for half a century a leader among the paper manufacturers of the Kalamazoo Valley, died on Thursday, May 4, at the home of his daughter, Mrs. Frank H. Milham, in Kalamazoo, at the age of 83 years.

Charles Ordway, inventor of many improvements in the design of the Yaryan evaporator, died on Saturday, April 29. He was born in Massillon, Ohio, on Feb. 8, 1858, and was thus in the sixty-fifth year of his age when he passed away. Mr. Ordway had been connected with the evaporator business for thirty years. Shortly after graduating from Wittenberg College, Springfield, Ohio, in 1877, he became associated with Homer T. Yaryan, inventor of the Yaryan evaporator, and was consulting engineer for the Yaryan company, which concern he succeeded in 1916.

Ernest Solvay, prominent in invention and industry through his originating the Solvay process for the manufacture of soda, died on May 27. M. Solvay was an octogenarian, having recently celebrated his eighty-fourth birthday, and was frequently styled "the Carnegie of Belgium."

Frank J. Parry, of Patchogue, L. I., secretary of the John H. Parry Tile Co., New York, died on May 23, as a result of a fall.

Market Conditions

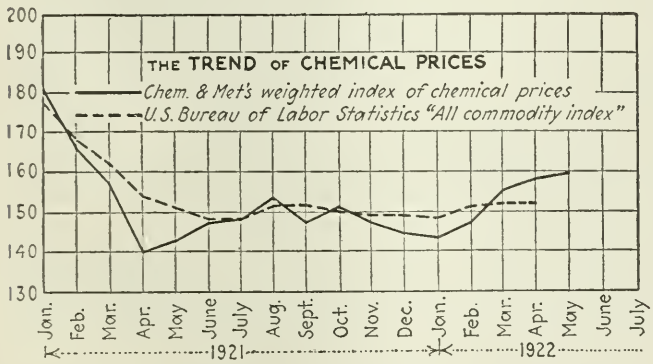
IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Better Business Conditions in the Chemical and Allied Industries

Marked improvement in the fundamental business situation is evident in practically every branch of industry. Striking progress was made during the past month, not only in production but also along distributive and consuming lines. Basic industries, such as those producing chemical and metallurgical products, have been especially affected by the business revival, since for the most part the fabricating industries are dependent upon them for the crude raw materials of commerce.

The phenomenal building boom which is spreading over the entire country is of broad industrial significance, for it means less unemployment and, therefore, increased purchasing power. The construction industry, according to the *Commerce Monthly*, is second only to agriculture when measured in the terms of the number of persons employed. It is natural, then, that much of the improvement in the so-called process industries is directly attributable to new



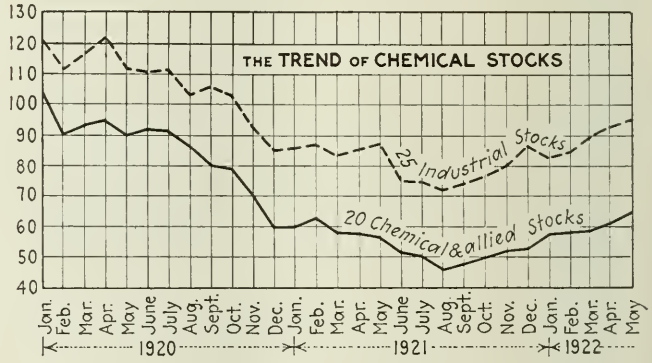
building. The F. W. Dodge Co. reported that the value of new construction in April, 1922, in twenty-seven northeastern states amounted to $353,161,900, which is far in excess of any month ever reported. The previous record month was July, 1919, with $317,698,000.

This activity has contributed greatly to the demand for metals. The iron and steel industry in April was operating at 75.2 per cent of its capacity. Steel ingot production of 2,896,966 tons was the largest output in any month since November, 1920, and was more than three times that of July, 1921. The output of pig iron in April, 2,072,114 tons, was the largest since January, 1921, and was over two and a half times that of last July. The orders for fabricated structural steel were almost equal to the capacity of fabricating firms, according to the Department of Commerce. Sales reported during April amounted to 115,247 tons by seventy-five firms having a capacity of 116,918 tons, or at the rate of 99 per cent of capacity.

Progress in the Process Industries

Other process industries prospering on account of the building boom include the production of glass, enameled ware and paint and varnish. One of the world's largest paint-manufacturing firms recently reported to the Philadelphia Reserve Bank that its gallonage production of house paint has increased 35 per cent over 1920 and over 30 per cent above 1921. The latter year, it will be recalled, was unusually good for the paint industry notwithstanding the general industrial depression.

The rubber industry, favored by low prices for its raw materials and a record demand from the automobile manufacturers, is working with feverish activity. The Philadelphia Bank sponsors the statement that tire production at Akron is at the rate of 85,000 tires a day. Even in the peak



of 1920 the daily output was but 110,000. This fact carries most significance when it is considered that before the depression it took 72,000 men to produce these tires, while today 77 per cent of the former record production is being accomplished with 27,000 men. Automobile production increased 30 per cent, from 152,647 passenger cars in March to 196,512 in April. This is the largest production since August, 1921, and compares favorably with the record of 220,000 in March, 1920.

The non-ferrous metal industries, emerging from their long period of stagnation, appear to be making a remarkable recovery. The prices for most of these products have finally reached the turning point. Copper has been one of the last of the basic commodities to respond to the tendency toward higher prices. The *Engineering and Mining Journal-Press* average for May was one-half cent above the March and April averages and since the first of April copper has shown a decidedly advancing tendency. The May average for lead of 5.4c. compares with 4.7c. in March and 5.1c. in April. The advance in zinc has been regular and long continued, the upward trend dating from February. Tin has not fluctuated widely, but has been successively stronger during the last 2 months. Quicksilver, antimony and tungsten are also advancing.

In certain of the process industries, however, improvement is inclined to be "spotty." The individual industries are often affected differently by the various economic factors. Thus the coal strike is beginning to be felt in some quarters and it is contended that if the dye industry were not so seriously curtailed because of the inactivity in the textile mills, there might be occasion for some concern re-

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	158.12
Last week	157.72
June, 1917	222
June, 1918	272
June, 1919	229
June, 1920	274
June, 1921	147
April 1918 (high)	286
April, 1921 (low)	140

This index number is based on the wholesale prices in the New York market for acetic acid, citric acid, hydrochloric acid, nitric acid, sulphuric acid, ethyl alcohol, methanol, anhydrous ammonia, ammonium sulphate, barium chloride, bleaching powder, borax, caustic potash, caustic soda, copper sulphate, formaldehyde, glycerine, potassium carbonate, saltcake, soda ash, crude sulphur, benzene, aniline oil, cottonseed oil and linseed oil.

garding supplies of the basic coal-tar products. Production in the petroleum industry has been proceeding considerably in excess of domestic consumption and exports. Stocks are piling up and temporarily the industry appears in a weaker statistical position. On the other hand the 10 per cent reduction in freight rates recently authorized by the Interstate Commerce Commission may be looked upon as a strengthening factor in the heavy chemical, fertilizer and other industries which in the past have suffered from excessive transportation charges.

The Financial Situation

Financially the month of May has been much the same as March and April. The lower money rates and the strengthening economic and industrial situation have added impetus to the unusual activity in the stock market. The advance during May was less spectacular than in the preceding month, but the underlying situation continued strong and practically all of the earlier gains were maintained. The *Wall Street Journal's* average of twenty industrial stocks opened the month at 92.74 and after suffering a very slight reaction during the middle of the month advanced to 96.63 on May 31. CHEM. & MET.'s average of the stock quotations for twenty representative chemical and allied industrials was 63.8 on May 1 and by the end of the month it had shown a gain of 4.4 points.

The effect of easier money rates has already been commented on in these columns. It is of interest to note, however, that on May 19, time money—i.e., fixed date loans—was quoted in New York at the lowest level since August, 1917. Thirty-day loans were negotiated at 3¾ per cent. Call money at that time was available at 3 per cent. The foreign exchange market during May was well sustained, and about the only outstanding feature was the new high levels reached by the pound sterling. On May 1 it was quoted at $4.42¾, on May 5 it had touched $4.44⅞ and on May 18 reached $4.44 15/16. By the end of May it had reached $4.48—the highest point since July 14, 1919.

Wholesale Prices

Commodity prices during May for the most part maintained their earlier gains and showed increased stability. The general index number of the Federal Reserve Board advanced 2 points as compared with the preceding month. The all commodity figure of the Bureau of Labor Statistics remained stationary at 152, but indexes for both chemical and metallurgical products advanced during April. CHEMICAL & METALLURGICAL ENGINEERING'S weighted index of chemical prices averaged 159.32 for the month of May, as compared with 158.04 during April. On May 24 this index had reached 160.49, but later receded somewhat on account of slightly lower prices for such basic chemicals as ammonium sulphate, caustic soda and cottonseed and linseed oils.

The Outlook

The review of the business situation would not be complete without some discussion of the outlook, particularly in the chemical and related industries. In general it may be safely contended that activity in these industries will continue without major reversals. As the summer season approaches there may be some slackening in the extreme pace set during recent months, but there can be little doubt that genuine improvement in chemical and related industries is scheduled for next fall and winter.

The Beet Sugar Situation

"As a result of the war, the world's beet sugar production, due entirely to shrinkage in Europe, decreased from nearly 9,000,000 long tons in 1912-1913 to 3,500,000 long tons in 1919-1920. This production is again on the up grade, reaching nearly 5,000,000 long tons in 1921-1922. Cane-producing countries, endeavoring to overcome this great falling off, increased their production from 9,250,000 long tons in 1912-1913 to 12,500,000 long tons in 1917-1918, and to 11,500,000 long tons in 1921-1922; this development being largely in Cuba, where the production was increased from 2,500,000 long tons in 1913-1914 to an average of nearly 3,900,000 long tons in the past 3 years.

"Out of the past season's domestic beet sugar production of 20,200,000 bags (900,000 long tons), there remained unsold 5,700,000 bags (250,000 long tons), on March 31, 1922, compared with over 10,000,000 bags (450,000 long tons) a year ago."

The foregoing paragraphs are extracted from the letter by H. Reiman Duval, president of the American Beet Sugar Co., which accompanied the report of that company's operations for the year ended March 31, 1922. The financial statement showed a net loss of $3,134,046, after allowing for taxes, charges and inventory adjustments. Preferred dividends and minor adjustments increased the deficit to $3,455,455. In 1921 the American Beet Sugar Co. reported a net income of $133,509, equal to $2.67 a share on outstanding preferred stock.

President Duval reported that the past year was but a continuation of the "unbroken movement toward normal conditions—a period of falling prices, large losses, liquidations and readjustments." That the future is more promising is shown by the fact that stocks are at a lower level than at any time in recent years and that better financial conditions and increased buying power appear likely to continue throughout the year.

Census of Chemical and Fertilizer Plants

In a special compilation made for the Finance Committee of the Senate, the Bureau of the Census shows that there are 598 establishments in the United States engaged in the manufacture of chemicals. The capital employed is given as $484,488,412. Salary and wage payments total $97,188,958. These establishments pay $28,338,749 in federal taxes and $3,592,640 in state taxes. The value of the products of these factories in 1919 was $438,658,869. The average number of wage earners employed during that year was 55,586. The aggregate horsepower of the plants was 376,940.

There were 600 establishments engaged in the manufacture of fertilizer. Their combined capital was $311,633,259. The total of salary and wage payments was $36,934,732. The value of products in 1919 was $281,143,587. The average number of wage earners was 26,296. The primary power used amounted to 125,939 hp.

The New York Market

NEW YORK, June 5, 1922.

The effects of the holiday interruption and the approaching season of slackened production were somewhat evident in the chemical market during the past week although conditions on the whole were regarded as satisfactory. Apparently the hand-to-mouth buying policies pursued by the consumers and their disinclination to lay in heavy stocks of chemical products indicate that trading this year will be less affected than usual by the summer lull. A surprising number of chemicals formerly regarded as staple commodities and practically always sold on contract between producer and consumer are now figuring actively in the resale and speculative markets.

It is apparent, too, that a number of important price revisions are imminent. Thus in the coal-tar group higher prices are daily expected for benzene, toluene and perhaps other crudes and intermediates. The reason for this is that the coal strike is beginning to pinch in some quarters and is already seriously curtailing byproduct operations. Oxalic acid, notwithstanding its recent upward revision, continues to grow firmer and higher prices are generally demanded. On the other hand, the new prices for ammonium sulphate and nitrate of soda are expected to be considerably lower than the present schedules and the buyers of these commodities naturally prefer to await the official announcement of the producers.

General and Special Chemicals

Acetic Acid—The market for the various strengths of acetic acid was considerably easier during the week. Glacial could generally be bought at 8½@9c. in carlots, but it was evident that in some large sales the former figure was

shaded to 8c. or even less. The 28 per cent strength was available at $2.25 per 100 lb.—a reduction of 10c. from last week's quotations.

Ammonium Sulphate—New prices for this article have not yet been announced, but it is rumored that sales are being made at $3 or less per 100 lb. The open price for f.a.s. material at New York is $3.25.

Barium Chloride—Barium chloride for immediate delivery is quite generally quoted around $100. Imported material to arrive in June and July has been sold at or below $90. Domestic producers report an active demand for their June output at $100.

Caustic Soda—The alkali market continues to maintain its previous strength and the large producers are reporting excellent business. Standard brands of solid caustic are being offered for export at $3.85@$3.90 per 100 lb. f.a.s. New York. Domestic shipments from New York are at $3.75. Contract prices for solid are said to be at 2½c. per lb., basis 60 per cent, works.

Copper Sulphate—This product is extremely scarce and prices are nominally quoted at 6c. per lb. An unprecedented demand from agricultural consumers and the higher prices for the metal are said to be the explanation.

Glycerine—The outstanding incident in this market last week was the announcement that the Japanese Government had placed an order in Great Britain for 250 tons of dynamite glycerine at a figure approximating 14 cents. The domestic market for chemically pure remains unchanged—refiners quoting 14¾@15c. in bulk.

Nitrate of Soda—Slightly lower prices prevail for spot material, with goods for future delivery offered at $2.25@$2.60. Large shipments have recently been received and the market is apparently well supplied. The price agreement between producers is soon to expire and lower prices are expected.

Oxalic Acid—A further advance in this acid brings the price up to 14@14¾c. for carlots at works. A noticeable scarcity of spot material has resulted in 15c. being demanded by first hands.

Prussiate of Soda—With the exception of a 10-ton lot on Saturday, but very small quantities of this material have reached the New York market and prices have varied over a wide range. Some sales early in the week were reported as low as 21c., but in general 23@25c. was asked for spot goods. Shipment material was quoted at 20½c.

Sal Ammoniac—The gray, granular material was obtainable from the domestic producers at slightly lower figures. Their price for carlots was 7⅞@8c. The imported sal ammoniac was selling at 7@7¾c.

Sodium Acetate—One large manufacturer was asking 5½@6½c. for carlots, but in other quarters this commodity was still available at its former price, 5@5¼c.

Coal-Tar Products

Aniline Oil — Some sales are reported at less than the manufacturers' quotation of 15@16c.

Benzene—An upward revision of benzene prices is considered likely, due pricipally to the curtailed production caused by the coal strike.

Beta-Naphthol—The market for this commodity has been unsteady and generally weaker. A number of producers quote 23c., where 25c. was the predominating figure a week ago.

Naphthalene—Considering the season, business in naphthalene may be regarded as fair. Some lower prices were obtainable, though generally from dealers rather than manufacturers.

Phenol—The scarcity of this product has strengthened its price considerably and the U.S.P. grade is quoted nominally at 14@15c., with the latter figure the more prevalent.

Linseed Oil and Naval Stores

Linseed Oil—Coincident with the lower flaxseed prices this oil has suffered another decline and it is generally reported that 82@83c. per gal. for carlots is the prevailing price. The immediate future is not certain, but many are inclined to think that a return to prices of a few months ago is easily possible. On the other hand, an early enactment of the new tariff will tend to sustain present high prices. Imported oil is offered at 77@78c., duty paid, for June arrival.

Turpentine—Market somewhat easier and prices are declining slightly.

Rosin—The advances predicted in these columns last week have resulted in the following prices per barrel of 280 lb., ex-yard: B, $5.45; D, $5.70; E, $5.90; F, $6.10; G, $6.15; H, $6.20; I, $6.20; K, $6.40; M, $6.70; N, $6.90, W.G., $7.75 and W.W., $8.25.

The Chicago Market

Chicago, Ill., June 1, 1922.

The general tone of the industrial chemical market in this section is firmer. Imported chemicals in particular are very firm and price advances are numerous. It was generally reported that while stocks were sufficient for present needs any unusual demand would cause a shortage. Consumers are beginning to show more confidence in the market and in some quarters business could almost be called brisk.

Industrial Chemicals

Spot stocks of the alkalis are reported to be only moderate and the tone of the market is slightly firmer. Small or moderate lots of *caustic soda* are available at $3.85@$3.95 per 100 lb. for the solid and $4.35@$4.50 for the ground. *Caustic potash*, while unchanged as to price, is exceptionally firm, and imported 88-92 per cent material cannot be located under 6¾c. *Soda ash* is reported to be moving well at $2.20@$2.30 per 100 lb. for 58 per cent material in cooperage.

Alums are moving only in a routine way and are unchanged as to price. *Potash alum* is available at 4½c. per lb. for the lumps and 5½c. for the powdered. *Barium chloride* is exceedingly scarce and only a few scattered lots are available at $120@$130 per ton. Owing to the strength of the metal, *copper sulphate* has been advanced to 6c. per lb. by the leading factors. A good movement is reported at this new figure. *Sal ammoniac* is in fair request and the white granular is offered at 7¾@7⅞c. per lb., the higher figure representing the prevailing price for domestic goods. A slightly better demand is to be noted for *carbon tetrachloride* and resale material in large drums is quoted at 10@10½c. per lb. No change is announced in the price of *furfural*, which is available at 50c. per lb. *Formaldehyde* continues dull and easy at 10c. per lb. for single barrels. This price can easily be shaded with a firm order. *White arsenic* is firm at 8@8½c. per lb. for small or medium quantities. *Glycerine* is exceptionally dull and supplies of the c.p. material can be bought at 14c. per lb., bulk basis.

Bichromates are in an easy position but are unchanged as to price. *Potassium bichromate* is offered at 11¾c. per lb. in single cask lots and the soda in similar quantities at 9@9½c. *Potassium permanganate* is dull and easy, with holders of spot goods asking 16c. for the U.S.P. crystals. Cabled quotations from abroad are slightly lower, which had a disturbing effect on the market. The prussiates are probably the firmest items on the list, the firmness no doubt due to the increasing scarcity of supplies both here and abroad. Practically nothing can be had from abroad for immediate delivery and only small quantities are available for the future. *Red prussiate of potash* is still off of the market and the yellow is very scarce at 34@36c. per lb. *Hyposulphite of soda* continues to move in a routine way at $3.85 per 100 lb. for pea crystals in barrels.

Linseed Oil and Naval Stores

Lower prices on *linseed oil* are predicted by a leading factor; however, the movement to the consuming trade continues very good. Boiled oil today is quoted in 5-bbl. lots at 93c. per gal, with the usual 2c. reduction on the raw.

Turpentine is scarce and the movement very good. The tendency of this material is toward higher prices, which is no doubt stimulating sales to a certain extent. Today's price on 5-bbl. lots is $1.05 per gal. *Rosins* are reported to be getting firmer every day, with a good movement. The WG grade is quoted today in less than carlots at $8.75 per 280 lb.

The Iron and Steel Market

PITTSBURGH, June 2, 1922.

The steel market has become quieter still. There is a fair volume of activity in the aggregate, but the turnover is much lighter than in February, March and April. Buying of steel at present is chiefly against newly developed requirements, the regular buyers, jobbers and manufacturing consumers being on the whole well covered for some time to come. Freight-car buying has perhaps been at a slightly lower rate in the past week or two. The automobile trade does not appear to be buying much steel at the moment, although the production of cars is substantially at record rate. Lettings of fabricated steel contracts represented 77 per cent of the shop capacity in March and 99 per cent in April, the high month since July, 1918, but May lettings are now estimated at only about 66 per cent. In fact, there is no important line of steel consumption outside of the automobile trade that presents the appearance today of using as much steel as it did in 1912 and 1913, yet the production of steel is at a rate 25 per cent greater than in those years.

The change in the market situation in the past fortnight, whereby there is less search by buyers for early delivery material, is probably attributable not to decreases in buyers' actual requirements but to a change in buyers' appraisals of the prospects of steel production, there being less fear that the steel mills will be unable, on account of the coal strike, to maintain their operations. Certainly the record of the first two months of the coal strike is impressive, for the mills have increased their production in this time. Last December steel ingots were produced at an annual rate slightly under 20,000,000 tons. By April 1 the rate had risen to about 35,000,000 tons. The rate today is about 38,000,000 tons, and the average rate since April 1 has probably been all of 37,000,000 tons. This means production of finished rolled steel at the rate of 2,600,000 net tons a month in the past two months. Besides this amount of steel, the tonnage assigned to any one line of consumption seems small, hence most experienced observers have doubts whether all the steel shipped is actually passing into ultimate consumption.

STEEL PRICES

Steel prices are firm all along the line, as follows: Bars, shapes and plates, 1.60c.; blue annealed sheets, 3.40c.; black sheets, 3.15c.; galvanized sheets, 4.15c.; hoops, bands and hot rolled strips; 2.25c.; standard steel pipe, 71 per cent basing discount; plain wire, 2.25c.; tin plate, $4.75. Nails are held at $2.40 by the leading interest and at $2.50 by the independents. The fact that the leading interest has failed to make an advance in nails, in the circumstances, may be regarded as significant of Steel Corporation's general policy. In most of the lines named some independent producers are quoting higher prices, and are probably securing them on small tonnages for early deliveries, but on the whole the volume of such business is hardly sufficient to suggest that the market is likely to reach higher levels.

A decision as to freight rates on iron ore from Lake Superior mines to lake is momentarily expected, the prospect being that there will be a reduction of 25 cents, making the rate from the Mesabi range 75 cents. Season prices for Lake Superior ore will then be developed, and will likely represent a reduction of at least 50 cents from the 1921 schedule, when Mesabi non-bessemer was $5.55 f.o.b. Lake Erie dock. A 50-cent reduction would include the 25 cents mentioned, a 10-cent reduction in the vessel rate, and a 15-cent concession by the ore producers themselves. The general rate reduction ordered last week by the Interstate Commerce Commission will apply to iron ore from Lake Erie docks to furnaces, and to coal, coke, limestone, pig iron, scrap and other rates generally, averaging a 10 per cent reduction. With the prospective reduction in Lake Superior iron ore the average cost of making pig iron at Northern furnaces will decline, say, $1.25 or $1.50 per ton, and the reduction in the cost of making steel will be about the same amount. As pig iron and steel prices are subject to so many influences, a decrease of this amount in cost would hardly be identified in market prices. The part of blast-furnace cost attributable to ore is largely theoretical, as the furnaces still have large piles of ore.

Sodium hydroxide (caustic soda) solid, 76% flat, drums, resale	100 lb.	3.85 – 3.90	3.95 – 4.25
Sodium hydroxide (caustic soda), ground and flake, contracts	100 lb.	3.85 – 4.00	4.30 – 4.50
Sodium hydroxide (caustic soda) ground and flake, resale	100 lb.	4.00 – 4.15	4.40 – 4.60
Sodium hyposulphite	lb.	.03 – .03¼	.03½ – .04
Sodium nitrite	lb.	.08¾ – .09	.09¼ – .09½
Sodium peroxide, powdered	lb.	.28 – .30	.31 – .35
Sodium phosphate, dibasic	lb.	.03½ – .04	.04¼ – .04½
Sodium potassium tartrate (Rochelle salts)	lb.	..... –	.18 – .21
Sodium prussiate, yellow	lb.	.25 – .25½	.25½ – .25¾
Sodium silicate, solution (40 deg.)	100 lb.	.85 – 1.00	1.05 – 1.25
Sodium silicate, solution (60 deg.)	100 lb.	2.35 – 2.50	2.55 – 2.90
Sodium sulphate, crystals (glaubers salt)	100 lbs.	.95 – 1.05	1.15 – 1.50
Sodium sulphide, fused, 60-62 per cent (conc.)	lb.	.03¾ – .04½	.04½ – .05
Sodium sulphite, crystals	lb.	.03½ – .03⅝	.03¾ – .04½
Strontium nitrate, powdered	lb.	.09½ – .10	.10¼ – .12
Sulphur chloride, yellow	lb.	.04½ – .05	.05½ – .06
Sulphur, crude	ton	18.00 –20.00	..... – .....
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.	..... –	2.25 – 3.10
Sulphur, roll (brimstone)	100 lb.	..... –	2.00 – 2.75
Talc—imported	ton	30 00 –40 00	..... – .....
Talc—domestic powdered	ton	18 00 –25 00	..... – .....
Tin bichloride	lb.	.09 – .09½	.09¾ – .10
Tin oxide	lb.	..... –	.35 – .37
Zinc carbonate	lb.	.14 – .14½	.14¾ – .15½
Zinc chloride, gran	lb.	.06 – .06½	.06¾ – .08
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08¼ – .08½
Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.15 — .16
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.50 — .55
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.50 — .55
Beta-naphthol, tech	lb.	.23 — .26
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.53 — .55
Cresylic acid, 95-97%, dark, in drums	gal.	.48 — .50
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.65 — .70
Dimethylaniline	lb.	.36 — .38
Dinitrobenzene	lb.	.22 — 25
Dinitroclorbenzene	lb.	.22 — .24
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .65
H-acid	lb.	.85 — 1.00
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.09 — .11
Monoethylaniline	lb.	1.05 — 1.25
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.08 — .08
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17
Ortho-amidophenol	lb.	.40 — 2.50
Ortho-dichlor-benzene	lb.	2.15 — .20
Ortho-nitro-phenol	lb.	.70 — .75
Ortho-nitro-toluene	lb.	$0.10 — $0 13
Ortho-toluidine	lb.	.14 — .18
Para-amidophenol, base	lb.	1.25 — 1.30
Para-amidophenol, HCl	lb.	1.30 — 1.35
Para-dichlorbenzene	lb.	.13 — 16
Paranitroaniline	lb.	.75 — .77
Para-nitrotoluene	lb.	.55 — .65
Para-phenylenediamine	lb.	1.55 — 1 60
Para-toluidine	lb.	.90 — 1.00
Phthalic anhydride	lb.	.35 — .38
Phenol, U. S. P., drums	lb.	.14 — 15
Pyridine	gal.	1 75 — 2 75
Resorcinol, technical	lb.	1.30 — 1 35
Resorcinol, pure	lb.	1.75 — 1.80
Salicylic acid, tech., in bbls.	lb.	.25 — .25½
Salicylic acid, U. S. P.	lb.	.26 — .26½
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.25 — .28
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.10 — .12
Sulphanilic acid, crude	lb.	.24 — .26
Tolidine	lb.	1.20 — 1.30
Toluidine, mixed	lb.	.30 — .35
Toluene, in tank cars	gal.	.25 — 28
Toluene, in drums	gal.	.30 — .35
Xylidines, drums, 100 gal.	lb.	.40 — .45
Xylene, pure, in drums	gal.	.40 — .45
Xylene, pure, in tank cars	gal.	.45 — ....
Xylene, commercial, in drums, 100 gal.	gal.	.33 — .35
Xylene, commercial, in tank cars	gal.	.30 — ....

Waxes

Prices based on original packages in large quantities f.o.b. N.Y.

Bayberry Wax	lb.	$0.20 — $0.21
Beeswax, refined, dark	lb.	.26 — .28
Beeswax, refined, light	lb.	.30 — .32
Beeswax, white pure	lb.	.35 — .40
Candellila, wax	lb.	.35 — .36
Carnauba, No. 1	lb.	.45 — .46
Carnauba No. 2, North Country	lb.	.25 — .25½
Carnauba, No. 3, North Country	lb.	.16 — .16½
Japan	lb.	.16½ — .17
Montan, crude	lb.	.04 — .04½
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.04½ — ....
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.02½ — ....
Paraffine waxes, refined, 118-120 m.p.	lb.	.02½ — .03
Paraffine waxes, refined, 125 m.p.	lb.	.03 – .03½
Paraffine waxes, refined, 128-130 m.p.	lb.	.04 — .04¼
Paraffine waxes, refined, 133-135 m.p.	lb.	.04½ — .04¾
Paraffine waxes, refined, 135-137 m.p.	lb.	.05 — .05¼
Stearic acid, single pressed	lb.	.09 — .09¼
Stearic acid, double pressed	lb.	.09½ — .09¾
Stearic acid, triple pressed	lb.	.10½ — .10¾

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50 gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl	280 lb.	$5.45	— $5.70
Rosin E-I	280 lb.	5.90	— 6.10
Rosin K-N	280 lb.	6.40	— 6.90
Rosin W. G.-W. W	280 lb.	7.75	— 8.25
Wood rosin, bbl	280 lb.	6.25	— ....
Spirits of turpentine	gal.	.96	— 96½
Wood turpentine, steam dist	gal.	.85	— ....
Wood turpentine, dest. dist.	gal.	.70	— .70
Pine tar pitch, bbl	200 lb.	.....	— 6.00
Tar, kiln burned, bbl. (500 lb.)	bbl.	.....	— 9.50
Retort tar, bbl	500 lb.		— 9.00
Rosin oil, first run	gal.	.36	— ....
Rosin oil, second run	gal.	.38	— ....
Rosin oil, third run	gal.	.46	— ....
Pine oil, steam dist., sp.gr., 0.930-0.940	gal.		1.10
Pine oil, pure, dest. dist.	gal.		.95
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.		.46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o b. Jacksonville, Fla.	gal.		.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.		.75
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.		.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.		.25
Pinewood creosote, ref.	gal.		.52

Fertilizers

Ammonium sulphate, f.a.s., N.Y.	100 lb.	3.25	— 3.40
Blood, dried, f.o.b., N. Y.	unit	3.55	— 3.65
Bone, 3 and 50, ground, raw	ton	27.00	— 28.00
Fish scrap, dom., dried, f.o.b. works	unit	3.10	— 3.20
Nitrate of soda	100 lb.	2.65	— 2.80
Tankage, high grade, f.o.b. Chicago	unit	3.00	— 3.10
Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	3.50	— 3 75
Tennessee, 78-80%	ton	7.00	— 7 50
Potassium muriate, 80%	ton	33.50	— 35.00
Potassium sulphate	unit	1.00	— ....

Crude Rubber

Para—Upriver fine	lb.	$0 18 —	.19¼
Upriver coarse	lb.	.13 —	
Upriver caucho ball	lb.	.13 —	.13½
Plantation—First latex crepe	lb.	.17½ —	.1 ½
Ribbed smoked sheets	lb.	.15½ —	.1 ¼
Brown crepe, thin, clean	lb.	.14 —	.
Amber crepe No. 1	lb.	.14½ —	..

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.11	— $0 11½
Castor oil, AA, in bbls	lb.	.12	— .12¼
China wood oil, in bbls	lb.	.13½	— 1¼
Coconut oil, Ceylon grade, in bbls	lb.	.08⅜	— .09
Coconut oil, Cochin grade, in bbls	lb.	.09¼	— .09½
Corn oil, crude, in bbls	lb.	.11½	— .11¼

Cottonseed oil, crude (f. o. b. mill)	lb.	$0.10 —	$0.10½
Cottonseed oil, summer yellow	lb.	.12 —	.12½
Cottonseed oil, winter yellow	lb.	.13 —	.13½
Linseed oil, raw, car lots (domestic)	gal.	.85 —	.86
Linseed oil, raw, tank cars (domestic)	gal.	.82 —	.83
Linseed oil, in 5-bbl lots (domestic)	gal.	.89 —	.90
Olive oil, denatured	gal.	1.15 —	1.17½
Palm, Lagos	lb.	.07½ —	.07½
Palm, Niger	lb.	.06½ —	.06½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.10 —	.10
Peanut oil, refined, in bbls	lb.	.12½ —	.13
Rapeseed oil, refined in bbls	gal.	.83 —	.84
Rapeseed oil, blown, in bbls	gal.	.85 —	.86
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.11½ —	....
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.10 —	....

FISH

Light pressed menhaden	gal.	$0.54 —	. ..
Yellow bleached menhaden	gal.	.57 —	....
White bleached menhaden	gal.	.56 —	....
Blown menhaden	gal.	.61 —	....

Miscellaneous Materials

All f.o.b. New York, Unless Otherwise Stated

Asbestos, crude No. 1, f.o.b., Quebec, Canada	short ton	$900 00	$1200.00
Asbestos, shingle stock, f.o.b., Quebec, Canada	short ton	90 00	—125 00
Asbestos, cement stock, f.o.b., Quebec, Canada	short ton	22.00	— 28 00
Barytes, ground, white, f.o.b. mills	net ton	17.00	— 23 00
Barytes, ground, off color f.o.b. mills	net ton	13.00	— 21.00
Barytes, floated, f.o.b. St. Louis	net ton	23.00	— 24 00
Barytes, crude f.o.b. mines	net ton	8.00	— 9.00
Casein	lb.	.14	— .15
China clay (kaolin) crude, f.o.b. mines, Georgia	net ton	6.00	— 8.00
China clay (kaolin) washed, f.o.b. Georgia	net ton	8.00	— 9 00
China clay (kaolin) powdered, f.o.b. Georgia	net ton	12.00	— 20.00
China clay (kaolin) crude f.o.b. Virginia points	net ton	8.00	— 12.00
China clay (kaoli n)ground, f.o.b. Virginia points	net ton	13.00	— 20.00
China clay (kaolin), imported, lump	net ton	14.00	— 20.00
China clay (kaolin), imported, powdered	net ton	30.00	— 35.00
Feldspar, No. 1 pottery grade	long ton	6.40	— 6.75
Feldspar, No. 2 pottery grade	long ton	5.75	— 5.90
Feldspar, No. 1 soap grade	long ton	7.00	— 7.50
Feldspar, No. 1 Canadian, for mill	long ton	21.00	— 22.00
Graphite, Ceylon lump, first quality	lb.	.06	— .07
Graphite, Ceylon chip	lb.	.04½	— .05½
Graphite, high grade amorphous crude	ton	15.00	— 30.00
Kieselguhr, f.o.b. mines, Cal	per ton	40.00	—
Kieselguhr, f.o.b. N. Y	per ton	55.00	— 60.00
Magnesite, calcined (crude)	per ton	8.00	— 12.00
Pumice stone, imported	lb.	.03	— .05
Pumice stone, domestic, lump	lb.	.05	— .05½
Pumice stone, domestic, ground	lb.	.06	— .07
Shellac, orange fine	lb.	81	— .82
Shellac, orange superfine	lb.	.84	—
Shellac, A. C. garnet	lb.	.62	— .63
Shellac, T. N.	lb.	.80	—
Silica, glass sand, f.o.b. Indiana	per ton	1.25	— 2.25
Silica, sand blast material, f.o.b. Indiana	per ton	2.25	— 4.50
Silica, amorphous, 250 mesh, f.o.b. Illinois	per ton	16 00	— 16.00
Silica, building sand, f.o b. Pa	per ton	2 00	— 2 75
Soapstone	ton	12.00	— 15.00
Talc, 200 mesh, f.o.b. Vermont	ton	7.00	— 12.00
Talc, 200 mesh, f.o.b. Georgia	ton	7.50	— 12.00
Talc, 200 mesh, f.o.b. Los Angeles	ton	16.00	— 20.00

Refractories

Bauxite brick, 56% Al_2O_3, f.o.b. Pittsburgh	per 1,000	$130.00
Chrome brick, f.o.b. Eastern shipping points	net ton	40–42
Chrome cement, 40-50% Cr_2O_3	net ton	23.00
Chrome cement, 40-45% Cr_2O_3, sacks, in car lots, f.o.b. Eastern shipping points	net ton	23.00
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	28–35
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	26–28
Magnesite brick, 9-in. straight (f.o b. works)	net ton	53
Magnesite brick, 9-in. arches, wedges and keys	net ton	70
Magnesite brick, soaps and splits	net ton	90
Silica brick, 9-in. sizes, f.o.b. Chicago district	1,000	30–32
Silica brick, 9-in. sizes, f.o.b. Birmingham district	1,000	33–35
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa	1,000	27–30
Silicon carbide refractory brick, 9-in	1,000	1100.00

Ferro-Alloys

Ferrotitanium, 15-18%, f.o.b. Niagara Falls, N. Y	net ton	$200.00 —	$225.00
Ferrochromium, per lb. of Cr contained, 6-8% carbon, carlots	lb.	.11 —	....
Ferrochromium, per lb. of Cr contained, 4-6% carbon, carlots	lb.	.12 —	....
Ferromanganese, 78-82% Mn, domestic	gross ton	67.00 —	69.00
Spiegeleisen, 19-21% Mn	gross ton	36 00 —	..
Ferromolybdenum, 50-60% Mo, per lb. of Mo	lb.	2.00 —	2 25
Ferrosilicon, 10-15%	gross ton	38.00 —	40.00
Ferrosilicon, 50%	gross ton	56 00 —	58.00
Ferrosilicon. 75%	gross ton	115.00 —	120.00
Ferrotungsten, 70-80%, per lb. of contained W	lb.	.45 —	.50
Ferro-uranium, 35-50% of U, per lb. of U content	lb.	6 00 —	.....
Ferrovanadium, 30-40% per lb. of contained V.	lb.	3.00 —	3.50

Ores and Semi-finished Products

All f.o.b. New York Unless Otherwise Stated

Bauxite, domestic, crushed and dried	net ton	$6 00 —	$12.00
Chrome ore, Calif. concentrates, 50% min. Cr_2O_3	ton	19 00 —	20 00
Chrome ore, 50% Cr_2O_3, f.o.b. Atlantic seaboard	ton	19 00 —	20 00
Coke, foundry, f.o.b. ovens	net ton	6 75 —	7 00
Coke, furnace, f.o.b. ovens	net ton	6 25 —	6 50
Fluorspar, gravel, f.o.b. mines, New Mexico	net ton	17 50 —	.....
Fluorspar, standard, domestic washed gravel Kentucky and Illinois mines	net ton	20 00 —	22 00
Ilmenite, 52% TiO_2, per lb. ore	lb.	.01½ —	.01½
Manganese ore, 50% Mn, c.i.f. Atlantic seaport	unit	.26½ —	.27
Manganese ore, chemical (MnO_2)	net ton	60.00 —	65 00
Molybdenite, 85% MoS_2, per lb. of MoS_2, N. Y.	lb.	.50 —	...
Monazite, per unit of ThO_2, c.i f., Atlantic seaport	unit	27 00 —	.....
Pyrites, Spanish, fines, c.i.f., Atlantic seaport	unit	10½ —	.11
Pyrites, Spanish, furnace size, c.i.f. Atlantic seaport	unit	.12 —	13½
Pyrites, domestic, fines, f.o.b. mines, Ga	unit	Nominal	
Rutile, 95% TiO_2 per lb. ore	lb.	.12 —	.....
Tungsten, scheelite, 60% WO_3 and over, per unit of WO_3 (nominal)	unit	2 50 —	2 75
Tungsten, wolframite, 60% WO_3 and over, per unit of WO_3, N. Y. C	unit	2 75 —	3.00
Uranium ore (carnotite) per lb. of U_3O_8	lb.	1 25 —	1.75
Uranium oxide, 96% per lb. contained U_3O_8	lb.	2 25 —	2 50
Vanadium pentoxide, 99%	lb.	12.00 —	14 00
Vanadium ore, per lb. of V_2O_5 contained	lb.	1.00 —	.....
Zircon, washed, iron free, f.o.b. Pablo, Florida	lb.	.04½ —	.13½

Non-Ferrous Metals

New York Markets

	Cents per Lb
Copper, electrolytic	13.625
Aluminum, 98 to 99 per cent	19.00–20.00
Antimony, wholesale lots, Chinese and Japanese	5.40–5 50
Nickel, ordinary (ingot)	36.00
Nickel, electrolytic	39.00
Nickel, electrolytic, resale	29.00–32.00
Monel metal, shot and blocks	32.00
Monel metal, ingots	35.00
Monel metal, sheet bars	38.00
Tin, 5-ton lots, Straits	31.75
Lead, New York, spot	5.65–5 75
Lead, E. St. Louis, spot	5.50
Zinc, spot, New York	5.75
Zinc, spot, E. St. Louis	5.25–5.30

OTHER METALS

Silver (commercial)	oz.	$0.72½	
Cadmium	lb.	1.15–1.20	
Bismuth (500 lb. lots)	lb.	2.00@2.10	
Cobalt	lb.	3.00@3.25	
Magnesium, ingots, 99 per cent	lb.	1.10	
Platinum	oz.	85.00@87.50	
Iridium	oz.	150.00@175.00	
Palladium	oz.	55.00	
Mercury	75 lb.	55.00	

FINISHED METAL PRODUCTS

	Warehouse Price Cents per Lb.
Copper sheets, hot rolled	20. 25
Copper bottoms	27.75
Copper rods	19.25
High brass wire	16.75
High brass rods	14 25
Low brass wire	18 25
Low brass rods	18 75
Brazed brass tubing	23 00
Brazed bronze tubing	28 00
Seamless copper tubing	20 75
Seamless high brass tubing	18.00

OLD METALS—The following are the dealers' purchasing prices in cents per pound:

Copper, heavy and crucible	10 25@10.50
Copper, heavy and wire	10 00@10.25
Copper, light and bottoms	7 75@ 8 25
Lead, heavy	3 90@ 4 15
Lead, tea	2½–2
Brass, heavy	4 50@ 4 75
Brass, light	4 00@ 4 25
No. 1 yellow brass turnings	4 00@ 4 25
Zinc	2.00@ 2.25

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and larger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named:

	New York	Chicago
Structural shapes	$2 48	$2 48
Soft steel bars	2 38	2 38
Soft steel bar shapes	2 38	2 38
Soft steel bands	2 98	2.98
Plates, ¼ to 1 in. thick	2 48	2.48

Construction and Operation

Arkansas

TEXARKANA—The plant of the Liberty Cotton Oil Co., Rose Hill, has been acquired by new interests, headed by N. P. Sanderson. A company is being organized to operate the property, and preliminary plans are being considered for extensions and improvements. Work will be commenced at an early date.

California

RICHMOND—The Pacific Sanitary Mfg. Co., recently organized with a capital of $2,000,000, will take over and operate three existing plants in this vicinity, heretofore controlled by officials of the new organization. These plants comprise an enameled-iron works at North Richmond, and two potteries on Barrett Ave., San Pablo. Plans are under way for extensive additions and improvements in all three plants, to increase the capacity approximately 100 per cent. N. W. Stern is president, and M. E. and E. S. Wangenheim, first and second vice-presidents, respectively.

OXNARD—The Associated Oil Co. has plans under way for additions and improvements in its local distributing plant to cost about $50,000.

COALINGA—The Continental Petroleum Refining Co. is planning for the construction of a series of new distributing plants in the San Joaquin Valley section. Property has been acquired at Hanford and Tulare, and the first plants will be located here. Other sites will be purchased at an early date.

Georgia

DUBLIN—The Southern Mfg. Co. will soon commence the construction of a new local plant for the manufacture of paints, varnishes, etc. A list of equipment is being arranged for installation, to include grinders, chasers, etc. L. H. Harville is general manager.

Illinois

MATTESON—The K. I. Herman Chemical Corp., 332 South Michigan Ave., Chicago, has commenced the construction of its proposed local plant, 3-story and basement, 60x140 ft., estimated to cost approximately $300,000. The general contract has been awarded to the Chicago Heights Construction Co., Chicago Heights. Harvey C. Miller, 112 West Adams St., Chicago, is architect. K. I. Herman is head.

CHICAGO—The Western Foundry Co., 3634 South Kedzie Ave., manufacturer of small gray iron and other metal castings, has filed plans for the construction of a 1-story plant addition, 76x138 ft., to cost about $15,000, exclusive of equipment. Frank D. Chase, Inc., 645 North Michigan Ave., is architect.

Louisiana

MONROE—The Atlas Oil Co. will commence the immediate construction of a new carbon mill and gasoline extraction plant in the Ouachita Parish district. The initial works, with equipment, will cost in excess of $200,000.

HOMER—The Atlantic Oil & Refining Co., Shreveport, has acquired the local property of the Gilliland Co., as well as holdings and plant of the same company at Haynesville, from P. J Hurley and George O. Baird, receivers. A consideration said to be $3,300,000, was given for the property, and the new owner has tentative plans under way for a number of additions and improvements.

Maryland

BALTIMORE—The Pyrocolor Corp., 503 East 88th St., New York, N. Y., manufacturer of special composition indestructible signs and kindred specialties, has tentative plans under consideration for the construction of a new local plant, and is in negotiation for the purchase of a suitable site. The Industrial Bureau of the Merchants' and Manufacturers' Association, Baltimore, is interested. Lawrence L. Stevens is engineer in charge.

Massachusetts

CHELSEA—The United Indigo & Chemical Co., Ltd., 176 Federal St., Boston, has work under way on an addition to its plant at 960 Broadway, to be 40x60 ft.

Michigan

IONIA—The Michigan Porcelain Tile Co. has awarded a contract to Glenn Pierce, Ionia, for the erection of a new 1-story and basement plant, 120x160 ft., to cost about $40,000, for the manufacture of tile and other burned clay products. Harry E. Kidder is general manager.

Missouri

ANNAPOLIS—The Annapolis Lead Co., 1217 International Life Bldg., St. Louis, has awarded a general contract to Stupp Bros., St. Louis, for the erection of its proposed new local plant, consisting of a crusher and concentrating building, power house and other structures. The plant will have an initial capacity of about 1,000 tons, and will cost approximately $400,000, including machinery. M. C. Rhodes is president.

KANSAS CITY—The Rubber Mfg. Co. is planning for enlargements in its plant, comprising the former works of the Rubber Products Co., recently acquired. It is purposed to increase the capacity to 1,000 tires and tubes per day.

New Jersey

NUTLEY—George LaMonte & Son, Kingsland Rd., manufacturer of paper products, have awarded a contract to Henry Doremus, 36 Orange St., Newark, for the construction of a 1-story plant addition, 60x80 ft. Fletcher-Thompson, Inc., Fairfield Ave., Bridgeport, Conn., is engineer.

YARDVILLE—A new company is being organized under the direction of Edward D. Newman, 29 Broadway, New York, N. Y., to operate the plant of the Zee Zee Rubber Co., recently acquired from the receiver, Henry Klag, Jr., for a consideration of $58,000. The works will be used for the manufacture of automobile tires and tubes, and a number of improvements will be made. The plant comprises two main 1-story buildings, 50x90 ft. and 40x90 ft., respectively, on a 3½-acre site.

NEWARK—The Federal Button Co., New Jersey Railroad Ave. and Market St., manufacturer of composition products, has plans under way for the construction of a 4-story addition to its plant at Wright and Emmett Sts., comprising the former works of the Klaxon Co., and recently acquired. Present buildings will also be remodeled and improved. The work, including machinery installation, is estimated to cost close to $300,000. S. Mendel is president; and Edward J. Duggan, secretary and treasurer.

DELAIR—The Kieckhefer Paper Co., Camden, manufacturer of paper products, has let a contract to Erwin & Leighton, 126 North 12th St., Philadelphia, Pa., for the construction of a new plant on the river front at Delair, N. J. The company is a subsidiary of the Kieckhefer Box Co., Milwaukee, Wis. J. W. Kieckhefer is president.

New York

ONEIDA—The Mohawk Asbestos Slate Co., Madison Ave., has tentative plans under way for the construction of an addition to its plant.

NORTH TONAWANDA—The Frontier Mfg. Co., Erie Ave., is considering plans for the rebuilding of the portion of its oil-manufacturing plant, destroyed by fire, May 23, with loss reported at about $22,000.

BROOKLYN—The Hugo Brand Leather Co., 178 William St., New York, has acquired the 2- and 3-story buildings, on site 71x100 ft., on 13th St. near 3rd Ave., South Brooklyn, for a new plant. The property heretofore has been held by the Charles A. Schieren Co., manufacturer of similar leather products.

BUFFALO—The Department of Public Works will take bids until July 11 for the construction of its proposed new filtration plant at the city water works, estimated to cost in excess of $3,500,000, including equipment. George G. Andrews, City Hall, is water commissioner. Plans will be available about June 11.

Oklahoma

WAYNOKA—The Santa Fe Salt Co. has plans under way for the construction of a new plant with initial output of about 200 tons of salt per day. The company has extensive salt deposits in Woods County, where the plant will be located. P. L. Clifton, Pomeroy, O., is president and manager; C. T. Cavan, Waynoka, is consulting engineer.

ALLEN—The Pacific Petroleum Co., Tulsa, has leased the local oil refinery of the Crystal White Refining Co., and in the future will operate the plant. It is proposed to develop at once a capacity for handling about 1,000 bbl. of crude oil a day. R. A. Irwin is general manager.

Pennsylvania

PHILADELPHIA—The Gill Glass Co., Inc., Amber and Venango Sts., will break ground at once for the construction of a 2-story addition, 85x120 ft., estimated to cost about $42,000. The general building contract has been let to William R. Dougherty, 1608 Sansom St. Francis D. Gill is president.

LIMERICK—The Vulcweld Rubber Co., Pottstown, has preliminary plans under way for the construction of a new local plant on property recently acquired, about 300x400 ft., to be equipped for the manufacture of automobile tires and other rubber products.

PHILADELPHIA—The Griburn Co. has leased a portion of the building at 721-23 Cherry St., for a new plant for the manufacture of lubricating oil products.

Texas

MINERAL WELLS—The Great Texas Oil & Refining Co., Fort Worth, has preliminary plans under way for the erection of a new local refinery with initial output of about 1,000 bbl. a day. The company is now operating plants at Breckenridge and De Leon, and is capitalized at $2,000,000. F. O. Stevenson is consulting engineer.

BRECKENRIDGE—The Hurley Gas Co. will soon commence the construction of a new gasoline extraction plant, on site about 2 miles from the city. It will be equipped for a capacity of about 6,000 gal. per day, with facilities for handling approximately 15,000,000 cu.ft. of gas daily. W. P. Dykemann and H. P. Lyons are in charge.

WICHITA FALLS—The City Council is planning for the immediate installation of a new filtration plant at the municipal waterworks. It is estimated to cost close to $25,000.

Virginia

GOSHEN—The N. Q. Speer Co. has plans under way for the installation of a new local plant for the production of glass sand, with estimated cost reported at about $30,000.

GLOUCESTER—The Roaring Springs Marl Lime Co. is planning for the immediate development of a tract of lime property, totaling about 10 acres, and will install machinery for an output of about 50 tons a day. A complete lime producing plant is contemplated. R. M. Janney heads the company.

NORFOLK—The City Gas Co. will make extensions and improvements in its artificial gas plant to cost about $175,000. Plans have been completed. T. Norman Jones is general manager.

West Virginia

NITRO—The Charleston Paper Mfg. Co., Charleston, W. Va., has acquired local property consisting of a number of buildings, on a tract of about 10 acres of land, for the establishment of a new plant. The structures will be remodeled and machinery installed at an early date, with cost estimated at approximately $350,000. Charles G. Hartje, Steubenville, O., is president of the company.

WARWOOD—The Wheeling Oxygen Co., Wheeling, has preliminary plans under consideration for the erection of a new local plant for the manufacture of commercial oxygen products.

MORGANTOWN—The University of West Virginia, Lee Coulter, dean, is completing plans and will soon take bids for the erection of a new 2-story chemical laboratory, estimated to cost close to $400,000, including equipment. Paul A. Davis, 3d, 1713 Sansom St., Philadelphia, Pa., is architect.

PADEN CITY—The Paden City Glass Mfg. Co. will soon break ground for the erection of a new plant addition, 80x140 ft. Bids for equipment will be called during June. The company has recently increased its capital to $150,000 for expansion. David Fisher is president.

Canada

HAMILTON, ONT.—The Firestone Tire & Rubber Co., Akron, O., will soon commence the construction of a new local plant, to be equipped for an initial capacity of 3,500 tires a day. It is proposed to have the factory ready for operation late in the fall.

Industrial Developments

RUBBER—The Armorcord Rubber Co., Morgantown, W. Va., has resumed operations at its local plant following a shutdown for a number of months.

The B. F. Goodrich Co., Akron, O., is arranging for an immediate increase in working schedule from 5 to 5½ days, with 8-hour working day as a minimum in all parts of the mills, and an overtime schedule operative in a number of departments. Production is now on a basis of approximately 18,000 tires a day.

The Hood Rubber Co., Watertown, Mass., has adopted a capacity schedule of production in all departments at its plant with the exception of the rubber footwear branch, which is now running at about 70 per cent of normal.

The Seiberling Rubber Co. is operating on a basis of 2,500 tires per day at its Barberton, O., and New Castle, Pa., plants, the former averaging 1,400 daily of the aggregate, and the latter 1,100 tires.

The Essex Rubber Co., Trenton, N. J., has adopted a double-shift basis of operation in a number of departments at its plant, giving employment to approximately 400 persons. The shock absorber department is running under exceptionally heavy production.

Tire plants at Akron, O., are now running at close to 90,000 tires a day, collectively, or about 90 per cent of maximum production. There is a shortage of skilled labor in the local industry, and a number of plants are advertising for help.

CEMENT—All cement mills in the Birmingham, Ala., district are operating on full time, with regular working force. The plants at Ragland, Leeds and Demopolis are increasing production to maximum and taking on additional employees.

Cement mills in the Lehigh Valley section of Pennsylvania are developing full production, including the Atlas Portland Cement Co., Lehigh Portland Cement Co., Alpha Portland Cement Co. and Coplay Cement Co.

IRON AND STEEL—The La Belle Iron Works has advanced operations to close to 85 per cent of normal at its Wheeling, W. Va., works. The company has inaugurated an improvement program at its Steubenville, O., plant, including blooming mill and open-hearth departments, and will add about 250 additional men to the working force as soon as completed.

The Replogle Steel Co. has blown in its furnaces at Wharton, N. J., following a shutdown for a number of months. During this period the furnaces have been rebuilt and a number of other plant improvements made. A good working quota is being employed and will be increased at an early date.

The Carnegie Steel Co. is now operating at its Homestead, Pa., works on a full 100 per cent basis in all departments. The plant at Duquesne, Pa., is also being brought up to this working basis, and will soon give employment to additional operatives.

A number of plants in the Shenango Valley section of Pennsylvania, vicinity of Sharon, are making ready for considerable increase in outputs. The Sharpsville Furnace Co. is rebuilding its stack and expects to have the unit ready for service at an early date. The Clair Furnace Co. is making improvements in its furnace stoves. The Shenango Furnace Co. is increasing the capacity of one of its stacks to 500 tons of pig iron a day. The expansion and improvement program at the different mills is estimated to cost close to $400,000.

The Wheeling Steel & Iron Co., Wheeling, W. Va., has brought its Top Mill blast furnaces up to 100 per cent capacity, following a curtailment of many months. The Yorkville plant of the company is running on a basis of close to 70 per cent of normal; the Belmont mill is operating at about 65 per cent of regular output; the Benwood plant at slightly better than 40 per cent, while the Martin's Ferry, O., mills are still on the inactive list.

The Gulf States Steel Co., Gadsden, Ala., is increasing production at its local plant; a night force is being assembled for the bar mill, and will be placed in service at an early date, making a double shift for this division of the works.

The American Sheet & Tin Plate Co., Sharon, Pa., has resumed operations at the last of its hot mills at the Sharon, Pa., plant, and is now running full. The company has also placed two more hot mills in service at its New Castle, Pa., works, bringing production up to 100 per cent with complete battery of twenty mills.

MISCELLANEOUS—The Hillside Mines Co. has started operations at its new fluorspar mill near Rosiclare, Ill., and will develop capacity production. The plant has been in course of construction for some time past and has a rated output of 25 tons of crude ore per hour, under single shift. It is electrically operated in all departments, and is one of the largest plants of its kind ever built. G. H. Jones, formerly vice-president of the Inland Steel Co., is head of the company.

The Holly Sugar Co. is planning for the early resumption of operations at its mill at Delta, Col. The plant was closed throughout 1921.

The Hercules Powder Co., Kenvil, N. J., is increasing production at its local plant and adding to the working force. The mill has been running under low production for a number of months past.

The American Smelting & Refining Co., Raritan Copper Co., Barber Asphalt Paving Co. and the Henry Maurer Co., manufacturers of firebrick, etc., all with plants at Perth Amboy, N. J., have resumed operations following a curtailment due to a strike of employees. Approximately 2,500 men have been out with a demand for increased wages. A settlement has been effected on a basis of 5 cents an hour advance in wage scale.

The Ralph Gypsum Co., Le Roy, N. Y., is arranging for immediate operations at its properties in the northwestern section of the city.

The United States Industrial Alcohol Co. is running at full at its plant at Curtis Bay, Baltimore, Md., and plans to double the present output during the coming months, following the completion of extensions and installation of new machinery, now under way. The company has reopened its different branch plants, including the works at New Orleans, La., closed during the early months of the year.

Capital Increases, etc.

THE GRAND RAPIDS PLASTER CO., Grand Rapids, Mich., has filed notice of increase in capital from $250,000 to $400,000.

THE HORWEEN LEATHER CO., 2015 Elston St., Chicago, Ill., has filed notice of decrease in capital from $1,200,000 to $500,000.

E. I. DU PONT DE NEMOURS & CO., Wilmington, Del., has disposed of a common stock issue of $2,000,000, the proceeds to be used for general operations.

THE DETROIT VARNISH CO., 1960 East Milwaukee St., Detroit, Mich., has filed notice of dissolution under state laws.

THE BURNSIDE TISSUE MILLS, INC., East Hartford, Conn., has filed notice of increase in capital from $150,000 to $400,000, for general expansion in paper plants.

THE FORMICA INSULATION CO., Cincinnati, O., has filed notice of increase in capital from $100,000 to $150,000.

THE AMERICAN RADIUM CO., 7 East 42nd St., New York, N. Y., has filed notice of increase in capital from $100,000 to $200,000.

THE ILLINOIS RUBBER CO., Chicago, Ill., a Delaware corporation, has filed notice of change of name to the Nuelle Rubber Co.

THE BOHEMIAN GLASS CO., INC., 17 West 42nd St., New York, N. Y., has filed notice of increase in capital from $25,000 to $250,000.

THE PHILLIPS PETROLEUM CO., 115 Broadway, New York, N. Y., is disposing of a bond issue of $600,000, the proceeds to be used for expansion, general operations, etc.

Property of the VALLEY FORGE MAGNESIA CO., Port Kennedy, Pa., will be sold by the receivers, George Flint and Wilfred S. Griffiths, including land, buildings and equipment.

THE SHELL-UNION OIL CORP., San Francisco, Cal., has arranged for a new preferred stock issue of $20,000,000, the proceeds to be used for general operations, expansion, etc.

New Companies

THE PAPER & PULP PRODUCTS CO., New Haven, Conn., has been incorporated with a capital of $100,000, to manufacture pulp and paper products, and chemicals for treatment of same. The incorporators are Grant Hammond, E. M. Sime and A. W. Chambers, 315 Exchange Bldg., New Haven.

HENRY SUNDHEIMER, INC., New York, N. Y., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are Henry Sundheimer, N. H. Maas and I. Skutch. The company is represented by Feiner & Maass, 66 Pine St., New York.

THE PACIFIC AMMONIA CHEMICAL CO., Seattle, Wash., has been incorporated with a capital of $300,000, to manufacture chemicals and chemical byproducts. Robert W. Greer is the principal incorporator. The company is represented by Raymond G. Wright, Leary Bldg., Seattle.

THE INDUSTRIAL CHEMICAL PRODUCTS CO., 31 East Woodbridge St., Detroit, Mich., has been incorporated under state laws to manufacture chemicals and chemical byproducts. The incorporators are Wilbert Kromis, Ray J. Smith and Clete Boyle, 1298 Beniteau Ave., Detroit.

THE EUGENE ARNSTEIN PAINT CO., 253 North Western Ave., Chicago, Ill., has been incorporated with a capital of 100 shares of stock, no par value, to manufacture paints, oils, varnishes, etc. The incorporators are Richard Alheim, Carl R. Hines and Alfred J. Parker.

THE RADIUM SULPHATE MFG. CO., Wilmington, Del., has been incorporated with a capital of $100,000 under state laws, to manufacture chemical and affiliated products. The company is represented by Horace G. Eastburn, Ford Bldg., Wilmington.

THE ART BRONZE & IRON WORKS, INC., Danville, Pa., has been incorporated with a capital of $50,000, to manufacture brass, bronze, iron and other metal products. D. J. Reese, Danville, is treasurer.

THE AMERICAN NATIONAL PETROLEUM CO., Paintsville, Ky., has been incorporated with a capital of $60,000, to manufacture petroleum products. The incorporators are M. F. Patrick, Hervie Stambaugh and D. G. Sublte, all of Paintsvilles.

THE INSULATALL PRODUCTS CORP., Buffalo, N. Y., has been incorporated with a capital of $100,000, to manufacture brick, tile and kindred products. A. C. Smith, 2342 Fillmore Ave., Buffalo, is the principal incorporator.

THE SILICON PRODUCTS CORP., Wilmington, Del., has been incorporated under state laws with a capital of $1,250,000, to manufacture commercial silicon and kindred specialties. The company is represented by the Delaware Registration Trust Co., 900 Market St., Wilmington.

THE RITZ CHEMICAL CO., 25 Division Place, Newark, N. J., has filed notice of organization to manufacture and deal in chemicals and chemical byproducts. Walter L. Swartz heads the company.

THE VI-CAR OIL & REFINING CO., Franklin, Ky., has been incorporated with a capital of $100,000, to manufacture refined petroleum products. The incorporators are D. T. Blakey and John S. Milllken, both of Franklin.

THE DALLES FOUNDRY CO., The Dalles, Ore., has been incorporated with a nominal capital of $8,000, to manufacture iron, steel and other metal castings. The incorporators are Carl and C. O. Mattes, and H. U. Martin, all of The Dalles.

THE ELLWOOD CHEMICAL CO., New York, N. Y., has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. The incorporators are F. Michelson, G. F. Borowski and C. E. Smith. The company is represented by Walter & Woolf, 120 Broadway, New York.

THE GULF TURPENTINE & ROSIN CO., Wilmington, Del., has been incorporated under state laws with capital of $600,000, to manufacture turpentine, rosin and affiliated products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE VENTURA-COLORADO OIL CO., Portland, Me., has been incorporated under state laws with capital of $300,000, to manufacture petroleum products. P. E. Coyle is president, and A. B. Ewing, treasurer, both of Portland. H. P. Sweetser, Portland, represents the company.

THE TRIANGLE SWEEPING COMPOUND CO., 1105 Garfield Ave., Chicago, Ill., has been chartered under state laws to manufacture chemicals, sweeping compounds, etc. The incorporators are Edwin W. Piper, Armin M. Freitagg and Edgar J. Scott.

THE LUNAPOL POLISH CO., INC., 363 Cal-

vert Bldg., Baltimore, Md., has been incorporated with a capital of $20,000, to manufacture chemicals, chemical compounds, polishes, etc. The incorporators are W. Arthur Darby, F. Stanley Porter and Theodore C. Waters.

THE HOUSTON CLAY PRODUCTS Co., Houston, Tex., has been incorporated with a capital of $10,000, to manufacture brick, tile and other burned clay products. The incorporators are W. M. Merritt, C. L. Hunter and George Kruger, all of Houston.

THE JAMES T. BLUE CHEMICAL Co., Washington, D. C., has been incorporated under Delaware laws with a capital of $25,000, to manufacture chemicals and chemical by-products. The incorporators are James T. Blue, Emery W. Williams and Joseph N. Gownder, all of Washington. The company is represented by the Delaware Registration Trust Co., 900 Market St., Wilmington.

Industrial Notes

THE DODGE SALES & ENGINEERING Co., Mishawaka, Ind., announces the removal of its New York City branch from 21 Murray St. to the new Dodge Bldg., located at the corner of Park Place, West Broadway and Murray St., and known as 53 Park Place.

THE AMERICAN INDUSTRIAL ENGINEERING Co., Chicago, has recently taken an order from the Tennessee Coal, Iron & R.R. Co. for the installation of complete low-pressure pulverized coal-burning plant for utilizing pulverized coal as fuel under one of the boilers in that company's new power plant at Ensley, Ala. The boiler under which this installation is to be placed is a Sterling 834 hp. designed to operate at 200 per cent of rating. A particularly interesting feature of this installation is in the system of control whereby the operation with this fuel will be practically automatic. The pulverized coal-burning equipment is designed with sufficient capacity to run the boiler on this fuel alone, but it will be operated in conjunction with blast-furnace gas, so that the two fuels can be used independently.

THE NITRO PRODUCTS CORP. and the SEYDEL MANUFACTURING Co. announce the merger of their interests and their future operation under the name of the Seydel Chemical Co., with manufacturing facilities in Nitro, W. Va., and Jersey City, N. J.

THE CELITE PRODUCTS Co., Chicago, Ill., announces that the first large freighter to be loaded entirely with Celite products recently left Port San Luis, Cal., bound for Atlantic ports by way of the Panama Canal. A second freighter is now receiving its cargo, and this will be followed by still another boat also devoted exclusively to their materials. Although the Celite Products Co. has made water shipments quite frequently in the past to the Atlantic coast, this is the first time that three entire vessels have been used to the exclusion of other cargoes. Loaded to capacity, these ships mark a departure from their established transportation method which will undoubtedly be repeated at frequent intervals.

THE METAL & THERMIT CORP., New York, announces the removal of its Pittsburgh branch office from 1427 Western Ave. to 801-807 Hillsboro St.

THE NATIONAL ANILINE & CHEMICAL Co. has moved its executive office to 40 Rector St., New York.

G. M. SHERMAN, formerly representing the Quigley Furnace Specialties Co., has connected with the Keystone Refractories Co. of New York and has been made New England sales manager, with offices at 818 Hospital Trust Bldg., Providence, R. I.

THE AMERICAN-LA FRANCE FIRE ENGINE Co., INC., and S. F. Hayward & Co., their subsidiary, have moved their New York offices to the Fisk Bldg., 57th St., between Broadway and Seventh Ave.

THE HILLSIDE FLUORSPAR MINES announce the completion of a new mine, comprising a shaft three-level development with the lowest level at 350 ft. The plant is electrically equipped throughout, including a mill concentrating building for separation of fluorspar from the impurities in the material as mined. The spar is stored in concrete bins drained and covered to insure dryness and thence loaded direct into railroad cars by belt conveyors. The mine on the original Rosiclare (Illinois) vein is now producing gravel and lump fluorspar.

THE RAYMOND BROS. IMPACT PULVERIZER Co., Chicago, Ill., has established a permanent Western office at 1002 Washington Bldg., Los Angeles, Cal. The office will be in charge of W. B. Senseman.

THE OLIVER CHEMICAL Co. has purchased a site at Penticton, B. C., and will commence at once to erect a factory for the manufacture of spraying compounds. The company, which really consists of John Oliver, Premier of British Columbia, and his two sons, has been operating an experimental plant at Vernon, B. C., for some time, and the company's sprays have met with so much favor in the Okanagan Valley, which is the principal fruit district in the province, that the larger venture has been decided upon.

THE QUIGLEY FURNACE SPECIALTIES Co., New York, announces that the American Supply Co., 135 Washington St., Providence, R. I., has been appointed agent for the Providence district to represent the Quigley company. The Quigley products are warehoused in Providence for quick delivery to local points.

THE RAYMOND BROTHERS ENGINEERING Co., Chicago, has recently been incorporated for the manufacture of equipment for "Rayco" pulverized coal systems for the utilization of pulverized coal as fuel in metallurgical operations, cement plants, and under boilers in power plants, and for the designing and installation of such systems. The new company takes over the business of the American Industrial Engineering Co. of Chicago, which has made a number of such installations, and L. H. Bergman, who has been secretary and chief engineer of the American Industrial Engineering Co., will remain as general manager of the new company. Mr. Bergman has been specializing for a number of years in the design, installation and operation of pulverized coal systems and is widely recognized as an authority on the subject, particularly in connection with the relation of furnace design to the most efficient use of this form of fuel. The Raymond Brothers Engineering Co. is a subsidiary corporation of the Raymond Brothers Impact Pulverizer Co., Chicago. The general offices of the Raymond Brothers Engineering Co. will be at 1315 North Branch St., Chicago.

THE COMBUSTION Co., 4256 North Western Ave., Chicago, Ill., has purchased from the receiver for the General Combustion Co., Chicago, the name, patent rights, drawings, patterns, trade marks and good will, including all contract records.

THE BRISTOL Co., Waterbury, Conn., on May 1 opened a new branch office at Philadelphia, Room 1311, Widener Bldg. C. C. Eagle, Jr., salesman and service engineer, is in charge.

THE ROTHACKER FILM MFG. Co., 1339 Diversey Parkway, Chicago, Ill., has made an eight-reel educational film for the Carborundum Co. entitled "The Jewels of Industry."

Two Italian chemists who have become acquainted to some extent with American methods and American materials through their war experience indicate their desire to make arrangements for representation of American firms in Italy. These men are interested in import of chemicals, chemical apparatus and related supplies. Those who desire to develop Italian markets may care to communicate with Anthony Costa, via le Observanza 22, Bologna, Italy, and Antonio Redaelli, via Lozzaro Palazzi 21, Milan, Italy.

H. H. Buckman and G. A. Pritchard of New York and Mineral City, Fla., announce that they have sold their interest in and severed their connection with BUCKMAN & PRITCHARD, INC., to the Titanium Pigment Co., Niagara Falls, N. Y., which will continue the business in the production of zirconium silicate and other specialties for enameling and affiliated service.

The pulverized fuel department of the Quigley Furnace Specialties Co. has lately been operated as the Quigley fuel systems department of the Hardinge Co., Inc. This pulverized fuel business has now been incorporated as the QUIGLEY FUEL SYSTEMS, INC., with general offices at 26 Cortlandt St., New York City. William H. Baker is president, W. O. Renkin managing engineer and L. W. Marso represents the company in the Pittsburgh district. The new company is entirely independent of the Hardinge Co., although Mr. Baker continues as vice-president and consulting engineer for the Hardinge Co. The company is just completing the largest installation of powdered coal in the world at the steel works of the Societe Anonyme Ougree-Marihaye at Liége, Belgium.

THE CENTRAL STEEL Co., Massillon, O., has appointed Frank Gibbons district sales manager of the Cleveland district, with headquarters at 904 Swetland Bldg.

THE GENERAL ELECTRIC Co. announces that following a meeting of the board of directors, held in New York May 16, C. A. Coffin retired as chairman and was succeeded by Owen D. Young, long associated with the company as vice-president. The position of president was filled by the election of Gerard Swope, president of the International General Electric Co., succeeding E. W. Rice, Jr., who requested to be permitted to devote his entire energies to the further upbuilding of the scientific, engineering and technical phases of the company's work in the broadest sense and who will become honorary chairman of the board of directors. Anson W. Burchard, for many years identified with the company as vice-president, with particular reference to public utilities and foreign investment, was elected vice-chairman of the board. J. R. Lovejoy, vice-president in charge of sales, was elected a director, as was also G. F. Morrison, vice-president.

Manufacturers' Catalogs

HENRY VOGT MACHINE Co., Louisville, Ky., is distributing, upon request, copies of its new bulletin on its new water-tube boiler, which is illustrated and described. The purpose of the bulletin is to outline the factors that should be given consideration when purchasing water tube boilers and to explain briefly the principles of design, the details of construction, and other features of the boiler.

THE CONNERSVILLE BLOWER Co., Connersville, Ind., has issued an attractive catalog, No. 20, on Connersville Cycloidal Pumps. This catalog is limited to illustrations and descriptions of cycloidal rotary pumps, which the company builds in a number of styles for a great variety of applications and in many sizes with displacements as small as 1/20 gal. per revolution and as large as 1,200 gal. per revolution. The construction of the pumps is given and also their advantages.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold a joint meeting with the Pacific Division of the Association, on the occasion of the annual meeting of the latter, in Salt Lake City, June 22 to 24.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Pittsburgh, Pa., Sept. 5 to 9.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 21, 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN FOUNDRYMEN'S ASSOCIATION is holding a convention and exhibit at Rochester, N. Y., this week. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, Canada, June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its nineteenth annual meet- at Bigwin Inn, Bigwin Island, in the Lake of Bays district, Ontario, Canada, on June 21, 22 and 23.

AMERICAN SOCIETY FOR STEEL TREATING will hold its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

ANNUAL SAFETY CONGRESS OF THE NATIONAL SAFETY COUNCIL will be held in Detroit, Mich., Aug. 28-Sept. 2.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NATIONAL FERTILIZER ASSOCIATION will hold its twenty-ninth annual convention at the Greenbrier, White Sulphur Springs, W. Va., the week of June 12.

NATIONAL LIME ASSOCIATION will hold its annual convention June 14-16 at the Hotel Statler, Cleveland, O.

NEW JERSEY CHEMICAL SOCIETY will meet at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

The following meeting is scheduled to be held in Rumford Hall, the Chemists' Club, New York: June 9—American Chemical Society, regular meeting.

Less Politics And a Better Tariff

WHILE Republicans and Democrats alike were inclined at first to be hostile to the Senate Finance Committee's proposal to introduce an element of flexibility in the tariff, there is an increasing recognition of the meritorious features of such a provision. Sentiment in that direction is being encouraged each day as the debate drags along in the discussion of details with which Senators can have only limited knowledge. It is becoming more apparent that machinery must be set up to give an opportunity for all concerned to be heard and to make possible the adjustments that economic changes require.

Those who oppose giving the President power to alter rates see in it not only the surrender of valuable prerogatives but fear that the President will be influenced to grant favors to special interests. As is well known, the plan for a flexible tariff contemplates a study of each case by the United States Tariff Commission. The President would act only on its recommendation after the particular case had been carefully studied by that body.

The idea is to handle tariff matters in much the same way that the Interstate Commerce Commission adjusts freight rates. If Congress were to attempt to pass upon the reasonableness of railroad rates, it is very apparent that intelligent action could not be had. With the increasing intricacy of the interchange of goods between countries, the tariff is entirely comparable, in diversity, with railroad rates.

If the flexible provisions are written into the law—and it is believed on Capitol Hill that this will happen—complaints probably will be filed with the Tariff Commission just as rate cases are now initiated with the I. C. C. With machinery much like that being operated by the Interstate Commerce Commission, careful consideration can be given to all phases of the particular duty involved and ample time provided for all concerned to be heard. This usually is not the case with Congressional committees. Notwithstanding the fact that the Senate Finance Committee was unprecedentedly liberal in the time it accorded witnesses, there were many instances where millions of dollars were involved and yet only two hours could be given to the entire discussion. When it is considered that Senators have manifold duties, there is little possibility of their being able to familiarize themselves with the economic situation surrounding the thousands of articles affected by a tariff bill. Furthermore if railroad rates could be adjusted only once in four years, great inequities would be occasioned. Just such inequities are being worked by the existing tariff policy, although these will not become fully apparent until the elastic system has been put into operation. A sudden change in industrial methods abroad frequently has resulted in very serious injury to an American industry. An example is had in the Canadian process for making acetic acid synthetically from acetylene. In other cases, actual practice frequently demonstrates that a rate is too high or too low. If the lesson of experience could be applied immediately, great losses and unnecessary burdens could be avoided.

The Need of Another Hearing on Chemical Warfare

DR. JOHN BASSETT MOORE, former Counselor of the Department of State and now a member of the lately created International Court of Justice, has been appointed to represent the United States on the Rules of Warfare Commission authorized by the recent Disarmament Conference. This High Commission is to consist of not more than two representatives each for the United States, Great Britain, France, Italy and Japan. The time and place of meeting are still to be determined. The names of the other members of the commission have not yet been made public.

We have been in communication with Dr. MOORE, with a view to providing a way for the presentation of a memorial in relation to chemical warfare. He reminds us that "the commission shall be at liberty to request assistance and advice from experts in international law, and in land, naval and aërial warfare," and points out that the question of assistance and advice from experts is one which the commission as a whole rather than any single member of it is to regulate. He very naturally desires to avoid saying anything just now which might place him in an attitude of speaking for the commission in advance of its constitution and organization.

We sympathize with him in his attitude. But that does not relieve us of our obligations. The learned International Disarmament Conference at Washington concluded that there is to be no more chemical warfare. There were two opinions presented on the subject: One, that it is wise to declare that there is and shall be no such thing, and the other, recognizing its existence, to establish measures of control. The conflicting opinions were presented respectively by

1. Statesmen and lawyers who are unfamiliar with chemical and physical processes, and representatives of the military service that do not know how to use chemical warfare for offense or to meet it in defense.

2. Chemists and physicists who recognize the constant possibility of the use of these munitions and that in a conflict at arms the force that uses chemical warfare against an unprepared army is almost certain to win. Supporting these was the smaller section of the military service that is familiar with chemical warfare

in offense and defense, and that realizes its effectiveness.

The members of the conference were themselves statesmen and lawyers, also unfamiliar with the processes and principles of science, and they listened with greater favor to the talk of the uninformed than to the advice of the informed. It was the old situation with which we are familiar in industry: When science gets a hearing the listeners either will not or cannot understand.

Here is a weapon of offense that doubles the potency of munitions, that can put regiment after regiment of enemy troops *hors de combat* at once, make them prisoners of war, and yet avoid a single fatal casualty. And it can also deal death at wholesale. The wrath of man is one of the devastating forces of nature, and when it bursts out into war it is, like fire and flood, a monster of destruction. Anger is madness, and we cannot reason with madness. Now chemical warfare is a weapon already developed and at hand. At any time in future wars chemical munitions will be available, like a loaded pistol, quickly made ready for use—and we are sure to discover that to forbid their use will not prevent it.

War is different from peace. There is not even a *code duello* among nations. Consider, for instance, the many phases of "military strategy" and how criminal and dishonorable the very substance of it is in times of peace! We repeat that in time of war we are dealing with madmen. Soldiers won't fight until their wrath is aroused. And the great conference in Washington agreed that in the event of such madness no signatory power was to misbehave in the matter of chemical warfare.

What will a signatory power do if it finds itself engaged with an enemy that uses so-called chemical munitions? How binding will that agreement be when such an enemy begins to conquer?

The High Commission that is about to assemble will consist of statesmen and lawyers. It is doubtful if a single man of ripe scholarship in physical science will sit in conclave. They will be men of great legal learning and of splendid type, judged by the American representative already named. What they will need to know is the ease and secrecy with which so-called chemical munitions may be launched when the fortunes of war turn against an army in battle. They will be eminent humanists who are familiar with the workings of the human mind in peace and in war. With the facts properly presented it is to be hoped that they will not, as did the Washington Conference, close their own minds to the unfamiliar language of science.

The subject is of supreme importance because civilization as we understand it is at stake. The weapon is always at hand, and it is sure to be used. To forbid it and let it go at that is like cautioning a Sicilian, engaged in a struggle to the death with his mortal enemy in a dark alley, not to draw his stiletto, or to request a negro to keep his razor in his boot during a fight.

It is the duty of the chemists of the United States and England, France, Italy and Belgium to explain the nature and operation of chemical warfare to the High Commission so that its members can really understand. It is difficult to explain, and the situation is difficult to meet, but that does not exonerate us from our duty in trying to make matters clear. Now is the time for our chemical societies to appoint committees to get the memorials ready to present.

Labor Unions Are Suable

ON THE simple and reasonable basis that it is utterly impossible to do justice otherwise, the United States Supreme Court held on June 5, in the case between the Coronado Coal Company and the United Mine Workers, that strike funds are assessable for damages and that a labor union is suable despite the fact that it is not incorporated.

The decision is of the greatest importance, for there has been agitation for 15 years or more in favor of legislation requiring the incorporation of labor unions. The argument was that the unions were evading responsibility for their acts and escaping the penalties of the law by not incorporating. The Supreme Court now settles this matter. The evasion of failing to incorporate cannot be employed. This seems elementary. It was possible to sue before there were corporations.

The law does seem to be growing more human as we build up interpretations of it. There is the Sherman law of July 2, 1890. For several years it was thought to be so drastic as to be unenforceable, and was considered a dead letter. There was agitation for amending it by writing in the word "reasonable," which would be rather unreasonable, for a "reasonable restraint of trade" would be contrary to the general spirit of law, which requires in most cases that a motive—or reason—be shown. Some years ago the Supreme Court settled the matter by asserting that the Sherman law must be interpreted "in the light of reason," which is really a totally different thing. That is, one cannot be convicted under the law on a mere technicality. Now the Supreme Court holds that a labor union cannot escape by a mere technicality.

On various occasions Congress in making appropriations for government expenditures has provided that no part of the funds should be used for the prosecution of labor unions. The limitation was tantamount to an admission that under the law labor unions are subject to prosecution, and Congress simply degraded itself. It did not enact legislation by imposing such limitations on the expenditure of funds appropriated. The limitations were obtained simply by the activity of the labor union lobby. The issue was not raised in such a manner that the general public would take a deep interest, particularly so since an appropriation is an annual affair, while legislation is permanent unless repealed. Should the labor unions now attempt to have Congress modify the law under which the recent Supreme Court decision was rendered, the whole thing would be brought out into the open and Congress would quickly have forced upon it knowledge that the public will not tolerate legislation to exempt labor unions from the operation of the laws of the land.

Repeatedly during the past few years distinguished leaders of thought in industrial relations have urged that laws in restraint of trade be applied to capital and labor alike. The incorporation of labor unions was advocated at President WILSON'S first Industrial Conference and stanchly opposed by Mr. GOMPERS, who proudly declared that it is impossible to incorporate human souls. This was a fine gesture, but it made no impression as a sound argument. Apparently the Supreme Court has visualized the whole situation very clearly and we may reasonably hope that henceforth labor unions will act and speak with due regard to their responsibility as organized bodies of men.

Byproduct Coking Continues to Gain

DESPITE the interruption of coal supply by the strike the output of byproduct coke has continued to increase since the first of the year until in April 2,227,000 tons was made. This represents about 90 per cent of the rate of production in 1920, when the average output was the maximum ever attained in the history of this industry—namely, 2,565,000 tons per month.

Not only is there this evidence that the byproduct industry is progressing steadily toward high-capacity operation, but also it has recently been announced that a tremendous extension will be made of the coke plants of the Eastern division of the U. S. Steel Corporation. It is stated that another plant even larger than the present Clariton plant will be erected in the near future in order to insure that the metallurgical coke supply of the East will be maintained without dependence upon the beehive branch of the industry.

Long ago the ultimate doom of the beehive oven was foreseen. But the war period and industrial conditions since the war show that even the more optimistic prophets were not unduly sanguine. Already much over half the coke supply comes from byproduct ovens. Soon it will be three-quarters of the total, and one might even dare to forecast that within a decade the beehive branch of the coke industry will be an altogether negligible part of the total when figuring the industry on a national basis. Locally it will, of course, remain in many districts an important or even dominating factor. But as a whole the more efficient system, the one which conserves the more valuable portions of coal will prevail.

Setting a Bad Example

ANNOUNCEMENT has been made by the American Petroleum Institute that hereafter the hydrometer scale with the modulus of 141.5 will be known as the "A.P.I. scale" (American Petroleum Institute scale). Thus at last the petroleum industry recognizes that hydrometers made according to this standard cannot properly be called "Baumé." Also this terminates the long-standing controversy between the Bureau of Standards and the petroleum industry regarding testing and use of this type of instrument.

It is most unfortunate that commercial considerations prevent the petroleum industry from abandoning altogether this hydrometer standard. It has no real excuse for existence on the score of science or technology. It originated from erroneous manufacturing practice and the fact that it has been permitted to take root and grow up within this industry is certainly not to the credit of petroleum technologists. It is commendable, however, that the scale is now recognized by a distinctive name and that the industry no longer attempts to use the A.P.I. standard under the name Baumé, as has often been the former practice.

There is really a question in our own minds as to whether the reasoning which led to the perpetuation of this standard is sound. The industry feels that a change in hydrometer standard would mean a change in specifications that would be unacceptable to the customers or else the loss of the certain fraction of a degree just at the limiting point of gravity specifications. This small change in the limit of gravity would be particularly important on such products as gasoline and would have real dollars-and-cents significance. Nevertheless it does seem unfortunate, to say the least, that the actual gravity of petroleum products cannot be recognized by hydrometer specifications which are acceptable in other industries and which could for all but this one commercial reason quite readily be used in petroleum marketing. It is certainly to be hoped that other industries will not emulate this example of special standards, for we already have far too many methods of expressing specific gravity.

Old Man, Go Back to School

OVER fifty years ago HORACE GREELEY created a magnificent slogan. When he said: "Go west, young man," he stimulated the imagination of the youth of his day and many followed his advice. We have no such slogan, but we have a message, "Go back to school, old man!" Study some more. Round out your development. Enlarge your point of view. There's an answer to "Why?" and "How?"

It is true that there are fewer chemists unemployed now than there were in August, so our friends in the employment bureau of the Chemists' Club tell us. Nor will there be great difficulty in placing this year's crop of graduates. It is also true that some firms are waiting till this year's graduates are ready before filling in their organizations because they are looking for cheap men. But what will be the fate of these graduates in industry? Their position almost without exception will be routine. Advancement will usually be very slow and a dead wall will be encountered over which there is no jumping in that company. Another company will treat them little better. Gradually from the control laboratory they will drift into the plant. Their progress will always be slow because they have not the technical equipment for pulling themselves above the average. This has been the experience of the vast majority of chemists and chemical engineers in the past. Their salaries remain low and their work stays routine.

As distinguished from the average is the group of chemists and chemical engineers who have taken this additional training. In general their progress through the research and operating departments is more rapid. They hold the desirable positions both from the standpoint of compensation and of interest. They had completed a college course before they entered professional training and then they had returned for graduate work and training in research. In short, their more mature mentality was stimulated by their study.

These two classes are not completely differentiated. They overlap. Men without additional training dominate. Men with it are submerged in routine. But the distinction is there. There is no escaping the essential fact. Success is in proportion to background, education and training.

And this year with the average weekly wage probably less than $25 and with the general history of the profession as it is, "Go back to school, old man." With two or three years of research behind you and with the true significance of Ph.D. after your name your services are much more easily marketable. With a year or two of research you will be able to lift yourself out of the technical routine. With a year or more of engineering studies or advanced courses you will be out of the routine class. Beg, borrow or—no, don't steal, but work for your expenses. It can be done. And the return on the investment is several hundred per cent.

Readers' Views and Comments

Atmospheric Pollution From Sulphuric Acid Plant Fumes

To the Editor of Chemical & Metallurgical Engineering

SIR:—I desire to call attention to two omissions in the article on "Atmospheric Pollution From Sulphuric Acid Plant Fumes," which you published under my name in your issue of May 24, 1922. Your readers may recall that the writer, in summing up the work of the committee of the American Institute of Chemical Engineers, stated that "the report of the committee places squarely upon the shoulders of the Manufacturing Chemists' Association the responsibility for further advances and action in this matter. Unfortunately in your abbreviation of the manuscript, however, you omitted the particular paragraph in the official report of the Institute's committee on which my statement had been based. That paragraph reads:

> The committee believes legislation and regulation concerning atmospheric pollution are more properly the subject for action by the chemical manufacturing associations, but that the Institute should hold itself ready to co-operate with such associations when called upon.

Of somewhat less importance but nevertheless of current interest in connection with the paper Dr. O'Gara is to present before the Institute's meeting at Niagara Falls on June 19 is the second omission:

> Your committee has especially requested Dr. P. J. O'Gara, head of the department of agriculture and semelter byproducts investigations of the American Smelting & Refining Co., Salt Lake City, Utah, to publish at the earliest possible date the conclusions of his notable work on atmospheric pollution.

I am grateful to you for the opportunity of bringing these matters to the attention of those of your readers who are interested in the important subject of atmospheric pollution.

JAMES R. WITHROW.

Columbus, Ohio.

Electric Steel in California

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the May 3 issue of CHEMICAL & METALLURGICAL ENGINEERING the author of the article on the Electric Steel Plant at the Southern Pacific Shops made certain statements upon which I desire to comment.

Under the subject of "Cost," in the second column, the statement is made that the electric furnace was selected for this plant on account of a smaller production cost, when compared to other forms of melting equipment. In referring to open-hearth operations the author then continues: "Inability to obtain 'hot metal' for the open-hearth furnace militated against this process." I do not see why any plant in California should exclude the open-hearth furnace from an installation on this account. California already has open-hearth furnaces in operation producing over 30,000 tons of steel a month, using scrap only, scrap and ore, or cold pig scrap and ore. These furnaces are producing ingot steel at less cost than can a Heroult furnace of the capacity described, comparing steel of the same grade and analysis. The inability to obtain hot metal is no well-founded reason for eliminating the open-hearth furnace, with the conditions for steel manufacture and supplies of raw melting stock existing on the Pacific Coast. The engineers who decided the choice of furnace for this plant may have desired to use the hot metal pigging process, but this is no interference unless an iron blast furnace were operating with a hot metal surplus from its casting requirements.

The author states also, "Furthermore, on account of the refractory nature of California iron ores, the erection of a blast furnace in this region is a very distant possibility." There are no refractory iron ores in California, considered as commercial ores of iron. The *nature* of the iron ores from a metallurgical or chemical standpoint has not contributed to the delay in establishing blast furnaces and reduction plants. In Placer County a plant operated in 1881 and produced over 5,000 tons of merchantable iron. The fact that California magnetites and hematites are suitable for pig-iron production has been demonstrated and proved since 1881, and in recent metallurgical history they have been proved suitable for electric reduction also. There seems to be current rumor in certain uninformed and misinformed circles on the Western Coast that the iron ores are not suitable for iron production. Until I read this article I never heard of a California iron ore as exhibiting any "refractory nature," and I have been working on the Pacific Coast with such ores since 1909.

R. C. GOSROW,

Chicago, Ill. Metallurgical Engineer.

Ido, the New Universal Language

To the Editor of Chemical & Metallurgical Engineering

SIR:—I note with interest the letter on "Ido, the New Universal Language," by Earl Walter Sutton, and I believe it will help the cause of introducing the international language. He said at the end, in regard to Europe: "I am informed that Esperanto is there meeting with the fate of Volapuk—obscurity." I believe he is wrong in this, as I follow the Esperanto movement quite closely and only wish it were spreading with the same rapidity in America as in Europe.

The difficulty that we international language people are chiefly confronted with, it seems to me, is prejudice against any artificial language. It would, therefore, be a good thing if all of us international language people could get together and agree not to throw one another down, or claim special perfection as against the others, but try to overcome the inherent prejudice of humanity.

In an article recently published in the new International Year Book, 1921 (Dodd, Mead & Co.), the writer of international languages seems to think that Esperantida (the latest) is going to win out.

I wish Mr. Sutton would put these three languages in parallel columns and let us know without prejudice what he thinks of their respective merits. I believe he would find that there is not 5 per cent difference in their virtues; hence the more reason for getting together and letting the truth hit where it will.

G. W. LEE,

Librarian, Stone & Webster, Inc.
Secretary, Esperanto Association of North America.

Boston, Mass.

Meeting of American Foundrymen and Institute of Metals

Rochester Entertains Foundry Trades—Prominent Metallurgists From Europe and Canada Guests of the Association—Ten Technical Sessions on Various Phases of Iron, Steel and Non-Ferrous Foundry Technique—Attention Also Paid to Industrial Relations

AFTER an interval of 18 months, spanning the business depression, the American Foundrymen and the Institute of Metals held a very successful joint meeting at Rochester, N. Y., June 5 to 9. According to custom, an extensive collection of modern foundry and shop equipment and supplies was on exhibition by over a hundred manufacturers and firms, and was visited by large numbers.

The selection of meeting and exhibition places was much happier than the last. Rochester possesses far more hotel accommodations than Columbus—an important detail bearing upon the enjoyment of any gathering—and the local committee having this matter in charge was very efficient. Technical sessions and the exhibits were held in Exposition Park, where a number of substantial buildings are set amid charming lawns, trees and flowers. Indeed, out of doors provided active competition with the business of the day.

As usual, many entertainments and plant visitations were provided. Governor Allen of Kansas was the principal speaker at the annual banquet, which, as is usual nowadays, was converted into bedlam by a company of "musicians" whose principal claim to fame is the possession of tremendous lungs and amazing endurance. Not the least of the feature events was a boat ride on Lake Ontario, where, in the apt language of the official announcement, "Lunch and supper will be served and refreshments will be provided continuously."

European Exchange Papers

Shortly after the Columbus convention the A.F.A. completed arrangements with the Institution of British Foundrymen for each association to have prepared annual exchange papers. Since that time the Association Technique de Fonderie de France and the Association Technique de Fonderie de Liége, the foundry associations of France and Belgium respectively, have consented to join in this arrangement, to promote greater friendship and respect of the foundrymen of these countries for each other.

F. J. Cook, of Rudge-Littley, Ltd., West Bromwich, Birmingham, England, presented the first exchange paper of the Institution of British Foundrymen, entitled "American vs. British Gray Cast Iron." Experience with poor quality of cast iron contained in many imported American machine tools, and reports appearing in American papers of failures of flywheels or of parts passing superheated steam have given the English foundrymen the impression that their gray cast iron is distinctly superior. While the methods of casting and breaking test-bars vary considerably in the two countries, it is possible to allow for these factors in making comparisons, and the author's works never produces metal testing as low as the electric furnace American iron described by George K. Elliott having similar silicon content but much lower sulphur and prosphorus.

Englishmen give especial attention to the relative amounts of combined carbon and graphite carbon, seeking a microstructure which contains (under 1,000 magnifications) fairly large areas of well-defined, laminated pearlite partly inclosed by thick sheaths of cementite, and relatively small thin graphite flakes. Silicon, sulphur and phosphorus are not so closely considered in England; in Mr. Cook's opinion, the distribution of phosphorus is of far more moment than its amount. If, after deep etching with 20 per cent HNO_3, bright, well-defined veins appear in a dark background (under 30 magnifications), the metal may be confidently expected to be far superior, even double in tensile strength, to an iron of the same chemical composition which appears with mottled, poor contrast after the same treatment. The author also expressed the opinion that this characteristic clear definition of phosphide existed in the pig by virtue of manufacture in slow-running furnaces with blast not over 900 deg. F., and persisted throughout subsequent melting.

New French Electric Furnace

R. Sylvany, of the Association Technique de Fonderie de France, described an electric furnace employed at Jarville during the war for the deoxidation of converter metal. Using 1,000 kg. per heat, with 3,000 amp. direct current at 80 volts, 8 tons of metal was handled per 24 hours, or one heat in 3 hours. The furnace is a closed crucible, set in a tilting device. It is charged and poured through the top, normally closed by a tight fitting cover. Through this cover passes a sheathed carbon electrode, of cross-section about half that of the crucible. Direct current is used; this electrode is positive and becomes hollowed out into an efficient heat reflector. Refining appears to be quicker with direct current, possibly because free oxygen is immediately attracted to the carbon electrode and consumed.

A strong magnesia bottom is shaped into a trough, to contain the first molten metal which forms electrical contact with a bundle of pure iron wires at either side, imbedded in a mixture of magnesia and tar, and united at the ends to give good contact. These electrodes operate during the melting or preheating period. For refining, current is drawn from the bath near its surface by an upper row of electrodes consisting of a great number of 10-mm. wires set into the side lining. Use of many small metal conductors gives uniform distribution of the current to all parts of the slag layer, and it is rapidly heated to attain correct fluidity and intense chemical action.

European Malleable Iron

Recognizing the evident superiority of American malleable iron, and its ability to compete with steel

castings, T. Levoz, of Auxonne, France, described efforts which the Europeans were making to improve their product. He ascribed the failures due to scoured molds to oxidized metal rather than superheated metal. Therefore it is essential that malleable shall be melted in furnaces capable of producing hot metal without forming ferrous oxide. Few European foundries have an output which warrants a reverberatory furnace; a cupola puts far too much oxygen into the metal; the crucible requires fine raw materials or excessively high temperatures. Germans have solved the problem by melting in the cupola and then blowing out the silicon in a side-blown converter. If a bottom-blown converter is used, ferrous oxides remain after the silicon has gone, and are reduced by carbon more or less promptly with the absorption of heat. Consequently the metal is chilled, it boils, traps slag, and liberates graphitic carbon at the moment of solidification even if it has been superheated sufficiently to pour a good casting. Using a side-blown converter and deoxidizing with aluminum, good results were obtained in France during the war.

Subsequently an electric furnace was added, making a triplex process. It is recommended that the cupola be provided with double row of tuyeres, thus separating the combustion zone from the fusion zone. A side-blown converter must be used, which ejects the slag as fast as it is formed and produces ferric oxide at the surface of the bath. An electric furnace then holds the metal for the necessary refining operations. Such hot, clean metal pours into castings of superior surface condition and even of very thin section, and can remain in the sand until quite cold. After annealing the physical properties approach those of cast steel.

One great advantage of the combination of equipment described is that the foundry possessing it can produce at will any kind of iron or steel casting.

Steel Castings

"Analysis Control in Acid Electric Steel Practice" was discussed by A. C. Jones, of the Electric Steel Co. of Chicago, who stated that off-analysis heats are often far more costly than imagined. A prolific cause of off-heats is frequent and unnecessary changes in furnace practice, trying to correct some fault which is not due to the quality of the metal. Continuous production of standard analysis by a carefully devised routine in a tight furnace will of course give the least trouble. Bridging over unavoidable delays is often done by charging heavy scrap into the hot empty furnace; this charge will lose more Si, Mn and C because it will be excessively oxidized during the wait. Especially avoid current interruptions during the melting-down period.

Low silicons are usually due to excessive oxide in rusty scrap or slow melting. The slag resulting is thin and watery, holding less than 30 per cent SiO_2. It should be partly removed, some silica sand scattered over the bath, bringing the refining slag to 50 to 60 per cent SiO_2, and the melt then thoroughly stirred. Finally add enough high-silicon pig to bring to analysis.

High silicon in just melted metal is recognized by very quiet metal when making a temperature test. It is often caused by reduction by carbon, if the melt contains more than 0.25 and is very hot. Excess silicon is best reduced by stirring in sufficient ore.

Carbon is seldom too high, unless there is electrode trouble. It can be lowered somewhat by an excessively siliceous slag, but the reaction adds silicon to the metal. Oreing down may be resorted to, but at greater time, expense and wear on furnace. Carbon can easily be brought up by pigging at the end of the heat; or in case all other elements are high, by dipping the electrodes into the metal.

Open-Hearth Design

Willis McKee, of Cleveland, Ohio, described recent advances in open-hearth design, particularly in reference to the use of water-cooled equipment about the ports, which enables a "blow-torch" flame to be maintained consistently. He further recommends eliminating gas-regenerating chambers, locating the producers close to the furnace and introducing the gas into the air uptakes directly. Using the blow-torch principle, the air and gas thoroughly mix before issuing into the furnace. The combination is at a good temperature, because the air has a higher temperature than usual, since its checkerwork is heated by the entire waste gases from the furnace. Furthermore, the scheme saves a checkerworkful of gas at each reversal, and enables many economies to be effected in the construction of the furnace.

Non-Ferrous Sessions

Physical Properties of Cartridge Brass

C. Upthegrove and W. G. Harbert, of the University of Michigan, presented a brief paper of the above title giving data to show that the differences in temper in brass persisted after cold-working. For instance, a coarse-grained brass resulting from a high anneal was softer than a fine-grained, low-anneal brass, and remained softer after equal amounts of work had been done upon them. (Heavier reductions naturally increase the hardness, but did not change the relationship.) These hardnesses persist and even increase slightly upon annealing at 200 deg. C., whereupon recrystallization sets in, progressing most rapidly for those having heavy cold-work, and all differences in hardness disappear after annealing to 550 deg. C., when a hardness of 60 Brinell (500 kg.) appears for this analysis—68.5 Cu, 31.5 Zn. Higher anneals cause this figure to fall slightly. (Brinell 43 at 750 deg. C.)

Electrical Properties of Nickel and Monel Wires

Supplementing data published in Bureau of Standards Circular 100, Messrs. Hunter, Sebast and Jones, of Rensselaer Polytechnic Institute, showed that nickel wires of lowest resistance (specific resistance 7.55 to 7.60 microhms per cm. and temperature coefficient of 0.0056 ohm per degree C. per ohm at 20 deg. C.). may be made in limited amounts by slitting a sound cathode sheet and rolling it into a wire.

If any quantity of such material is desired, the purest metal must be melted by having a hot vacuum furnace so designed to receive a charge of, say, 5 lb., and melt it very quickly so as to pour within a very few minutes. Even then about 0.75 per cent of manganese must be used to make a sound casting. Under such circumstances the specific resistance of 9.12 with temperature coefficient of 0.0049 may be had. The authors also publish curves comparing the relative resistance of electrolytic nickel, grade A, C and D, and Monel metal at temperatures varying from 20 to 1,000 deg. C. As would be expected, the specific resistance rises and the temperature coefficient falls with growing impurity. Furthermore, the curves show definitely the reversible

magnetic transformation at about 360 deg. C. to be lowered progressively with increasing impurities, arriving at 93 deg. C. for Monel. Magnetic releases operating at any temperature between those limits could apparently be constructed of nickel alloys of varying purity.

Embrittlement of Copper Wire on Annealing

Another evidence of the extreme sensitivity of high-grade metal to foreign substances was cited by T. S. Fuller, of the General Electric Co. He found that if high-conductivity copper wire was packed in sea sand in a closed iron pipe and annealed 1 hour at 800 deg. C. in an electrically heated furnace, it was rendered so brittle it would break on a right-angle bend. The trouble was thought to be due to reduction of CuO by hydrogen or carbonaceous gas derived from the steel or organic matter in the sand, whereupon some resulting gases of slow diffusibility accumulate in sufficient volume to wedge the grains apart—at least at the surface, the most dangerous region. Oxygen-free copper was not made brittle. Neither was commercial tough pitch wire, annealed in Al_2O_3 in a porcelain tube, or annealed in calcined sand in an electrolytic iron tube.

N. B. Pilling, of the Westinghouse Co., pointed out that copper may be deoxidized in molten c.p. salt, by H_2 derived from the dissociation of traces of water of crystallization. In fact it is at times extremely difficult to maintain non-reducing atmospheres. At other times copper does not seem to be so sensitive to its surroundings, as witness the everyday performance of brazing operations.

Technical Control in the Foundry

E. H. Dix, Jr., described the foundry at McCook Field, Dayton, Ohio, where all the castings for experimental aircraft parts are made and where the design and alloys are perfected before contracts are let for larger quantities. Their furnace equipment consists of stationary and tilting crucible furnaces, and a high-frequency induction furnace for melting refractory alloys or hardeners. Temperatures during melting and pouring are controlled carefully—base metal thermocouples protected by iron tubes are used in aluminum alloys. For quick readings iron-constantan "pyods" are useful. Bare No. 6 gage chrome-alumel wires spread wide apart may also be used—they waste away slowly, but are easily re-welded, and the metal lost does not harm the alloy. In brass or bronze a chromon tip protecting tube has been very satisfactory. Following is a table of temperatures used for the small castings used in aircraft:

Alloy	Melting Point Liquidus, Deg. F.	Maximum Furnace Temp., Deg. F.	Pouring Temp., Deg. F.
Cu 8, Al 92	1,148	1,400	1,200 1,300
Cu 10, Al 90	1,130	1,400	1,200 1,300
Cu 85, Sn 5, Zn 5, P 5	1,780	2,000	1,950
Cu 88, Sn 10, Zn 2	1,825	2,200	2,050
Cu 80, Sn 10, Pb 10	1,735	1,950	1,900
Cu 60, Zn 37+3 Hardener	1,600	1,800	1,700 1,750

An extended study has been made in order to locate the correct way to place a test coupon or to cast a test-bar so that it will really represent the condition of the finished casting. Separately cast test-bars have been decided upon; thereby all disputes as to methods of gating may be avoided. In correlating the properties given by such standardized test-bars to those of important castings it is the practice to pour several full-sized castings from the same heat, and those castings are tested as nearly as possible under the same stresses as they will receive in service. Many different heats are cast, varying the pouring conditions and the disposition of gates.

Microscopic examination of all heats is made. All the data—pouring conditions, physical tests, chemical analysis and metallography—are then collected on one card and filed. With a sufficient accumulation of such data, it is thought that in time very definite and valuable indications may be derived from the microscopic examination.

Metallic Oxidation at High Temperatures

One of the most important papers of the meeting was presented by N. B. Pilling and R. E. Bedworth, of the Westinghouse Co., in that it gave a new and stimulating idea on the subject of corrosion. The authors confine their attention to oxidation by atmospheric gases at high temperatures—i.e., temperatures where the solid phases participating in the reaction diffuse with high speed, and this diffusion has become the dominant force.

In the first place, noble metals are separated from base metals by the fact that the dissociation pressure of the oxides of the noble metals are equal to or above atmospheric pressure at temperatures below the melting point, whereas the corresponding values for the base metals are extremely minute. But the character of the first-formed oxide furnishes a further classification of base metals: If the layer of oxide formed takes up more space than the volume of metal which was oxidized to produce it, the oxide layer forms a tight fitting, solid sheet, thus impeding further oxidation. Computations made on this basis for twenty-three metals separate those which oxidize readily from those which do not. Some of the former—having a porous or cellular oxide structure—have been shown to oxidize at a uniform rate until all the metal has vanished. Compact oxide coatings, however, have been shown to grow at a rate which varies inversely as the thickness—i.e., "the speed of the reaction is not determined by any property of the metal at all, but by some combination of physical properties of the oxide." These properties of the oxide coatings are discussed, and an equation derived between the rate of oxidation and the temperature which closely agrees with experimental values.

Leady Bronze, So-Called "Engine Brass"

R. E. Lee and F. B. Trace, of Allegheny College, told in an interesting manner of an investigation undertaken to determine proper foundry practice to produce Cu: Sn: Pb alloys containing up to 30 per cent Pb without "segregation"—i.e., with a structure simulating that of a eutectic—despite the fact that the system is not truly eutectiferous and that 15 per cent is sometimes spoken of as the limit for lead in such alloys. Sometimes high lead is handled by addition of nickel or other "carrier."

It was found, however, that if the melt was superheated to 2,000 deg. F. (or 200 deg. higher if all virgin metal was used), deoxidized by phosphor copper and skimmed, the metal, which formerly tended to separate into two immiscible layers, becomes capable of more intimate mixing or even is mutually soluble. The charge is quickly dumped into an oversize pot, which gives the necessary stirring, and also chills it to 1,800 deg. F., whereupon it is poured into firmly rammed sand molds, and cooled in the mold. When a 5x10½-in.

bearing is made in this way it possesses high strength, and a fracture shows a uniform light color, free from dark "segregated" spots, even though it contains no nickel. Well-selected scrap may form all the charge except necessary additions to bring to analysis.

Melting Furnaces for Brass and Aluminum Alloys

A posthumous paper by T. H. A. Eastick emphasizes the fact that no "best" furnace or fuel existed for copper alloys. N. K. B. Patch, of the Lumen Bearing Co., agreed emphatically, saying that successful melting is a combination of fuel, furnace and brains, and if sufficient brains are available, almost any furnace will do. Therefore the character of the available help is as important as the first cost of a furnace or the fuel cost. The electric furnace is of considerable advantage in holding down melting losses in certain alloys which must be poured very hot, but often the open flame furnace will do just as well if the atmosphere is properly maintained. Jesse E. Jones, of the Westinghouse Co., recommended that large foundries diversify their equipment and thus be ready for any emergency, citing an incident where Mr. Marconi provided three independent sources of current to make sure that certain demonstrations would not fail for lack of power. Two sources did fail, but the third worked!

Aluminum foundrymen were unanimous in saying that a satisfactory furnace of large capacity was yet to be designed. When this arrived it would probably be an electric furnace, because the atmosphere is most easily controlled, although present designs left something to be desired. Robert J. Anderson, of the Bureau of Mines, in presenting his paper entitled "Aluminum and Aluminum-Alloy Melting Furnaces," recommended for sizable foundries an open flame furnace, barrel shaped, about 12 ft. long by 6 ft. in diameter. This should be operated with close temperature and atmospheric control, and additions of pig made periodically to match pourings, so as to maintain a molten bath at all times.

Apparently the iron pot holding 400 lb. of Al is widely used, even by large foundries, and many members spoke of methods whereby the life and performance could be bettered. Mr. Anderson said that forty-seven heats per pot was the average of many reports in his hands, and that the chemical composition of the iron did not seem to have much influence. A sound gray iron, preferably low in carbon, silicon and phosphorus, was as good as or even better than more expensive high-silicon irons. Many pots would fail in a very few heats, but that was ordinarily due to defective molding practice. W. M. Weil, of the National Smelting Co., said it was perfectly possible to get 300 heats from an iron pot if properly cared for. In the first place, the furnace setting should be deep, with at least 1 ft. for a combustion chamber below the pot. The burner is placed tangentially at the very bottom, so that the swirling flame envelops the pot without striking it. Furthermore the burner should be operated with a very slight deficiency in oxygen, so that scaling would not waste the pot and obstruct the heat flow. The inside of the pot is sand-blasted during the night and painted with lime and silicate of soda. It was further recommended that the pot be made somewhat deeper than the diameter, to reduce the surface of the bath.

John A. Lange, in a paper, "Melting Aluminum for Rolling Into Sheet," described the development of a quick melting furnace which on long campaigns has given the following performance:

	Charge		
	Virgin Metal	Clean Mill Scrap	Oily Stamping Scrap
Melting loss	9%	16%	31%
600 b.t.u. gas per 1,000 lb. Al	2,500 cu.ft.	2,800 cu.ft.	2,900 cu.ft.
Wt. of charge	1,100 lb.	850 lb.	850 lb.
Time to melt	23 min.	23 min.	23 min.

This furnace is also shaped like a drum, the chamber being 33 in. in diameter and 96 in. long, and tilts when pouring. One end has a 9-in. pouring opening, while the opposite has an 18-in. charging and skimming opening, closed by a swinging door, reducing the opening to 9 in. for the burner. Automatic air-gas mixing valves were installed. The drum makes a complete revolution in 4½ minutes, a feature which promotes uniform and rapid melting. The lining is of special 5½-in. low-silica firebrick, which withstands 10,000 heats.

About 1 lb. of cryolite is charged with the cold charge, and when melted about 4 oz. of $ZnCl_2$ scattered over the bath and the dross immediately skimmed. Temperatures of the furnace atmosphere should not exceed 1,800 deg. F. Metal is poured at 1,250 deg. F. into cast-iron ladles containing ½ teaspoonful of $ZnCl_2$, skimmed and poured into open-top slab molds about 12 x 18 x 1¾ in.

Natural-Gas Gasoline in 1921

The output of natural-gas gasoline in 1921 increased 23 per cent over that in 1920, but the market for natural-gas gasoline was rather unstable because of the depression in the petroleum industry, according to a preliminary statement of the United States Geological Survey. The statement is based on incomplete returns from the producers and is subject to revision. Seventy-five per cent of the output was recovered at compression plants and the remainder at absorption plants. The average daily production was 1,297,000 gal., as compared with 1,054,093 gal. in 1920. The average production per plant in 1921 was 408 gal., compared with 333,400 gal. in 1920.

A decrease in the value of natural-gas gasoline was naturally produced by the breaking of the market due to the depression in the petroleum industry. The total value in 1921 was about $6,000,000 less than in 1920. The prices received by the producers declined to 8 cents a gallon, and the average price as computed from the total output in 1921 was 5 cents less than in 1920. Although the output was greater, 5 per cent less gas was treated, so that the plants showed increased efficiency in 1921. The average yield of gasoline per thousand cubic feet of gas was 0.2 gal. greater in 1921.

Texas has become an active field for the natural-gas gasoline industry, with an output in 1921 that was 172 per cent greater than in 1920 and occupied second place in the list of producing states. California also increased its production, but West Virginia, which was second in rank, showed a decrease and occupied fourth place.

The following figures are for unblended natural-gas gasoline. It is understood that blending with higher grade gasoline is essential before the product can be used for motor fuel.

	Compression and Vacuum Process		Absorption Process	
	1920	1921	1920	1921
Number of plants	967	957	187	204
Gasoline produced, gal.	281,131,973	355,346,900	103,611,949	118,311,600
Average price per gal., cents	17.9	13	20.8	17
Estimated volume gas used, 1,000 cu.ft.	112,887,802	134,817,400	383,543,150	344,609,200
Average yield of gasoline per 1,000 cu.ft., gal.	2.49	2.6	0.27	0.4

Hydrogen Peroxide—A Novel Process for Its Manufacture

By H. A. Doerner

THE following experiments were carried out at the plant of the Chemical Products Co. in the year 1916 and the results of the work are embodied in a patent owned by that company. At that time the company was manufacturing hydrogen peroxide, using the usual phosphoric acid method, and was having difficulty in obtaining a supply of phosphoric acid of satisfactory quality. There were impurities in most of the acid then obtainable, which resulted in an inferior product. The expense of purifying the acid would have been serious and the plant was not equipped to do it. This situation led to an attempt to find some substitute for the phosphoric acid.

Since the barium salt formed by the action of the acid on barium peroxide must be separated from the hydrogen peroxide solution produced, it is evident that an acid which gives an insoluble barium salt must be used unless distillation is employed. Sulphuric acid cannot be used except in conjunction with phosphoric, because free sulphuric acid causes decomposition of the hydrogen peroxide. Carbonic acid is the only other cheap acid which forms an insoluble barium salt. Textbooks on chemistry state that hydrogen peroxide may be prepared by slowly adding barium peroxide to a carbonic acid solution according to the equation

$$BaO_2 + H_2O + CO_2 = BaCO_3 + H_2O_2$$

The use of carbon dioxide would effect three important advantages:

1. No impurities would be introduced by the acid.
2. The byproduct, barium carbonate, is more valuable than the barium sulphate produced by the usual method.
3. Carbon dioxide is cheaper than the phosphoric and sulphuric acids required by the usual method. Since the cost of liquid carbon dioxide as placed on the market is largely due to the expense of liquefying and to the overhead on costly containers, this economy can be greatly increased by operating the process near to a source of carbon dioxide, and using the gas at comparatively low pressure.

Experimental Tests Encouraging

Preliminary experiments in the use of carbon dioxide were not encouraging. The gas was bubbled through an emulsion of barium peroxide in ice water. The hydrogen peroxide decomposed nearly as fast as it was formed. Slowly adding the barium dioxide to ice water through which the carbon dioxide was bubbling gave only slightly better results. Nothing approaching commercial requirements in recoveries or strength of product could be obtained by the method as described in textbooks.

In comparing these experiments with the commercial method it seemed probable that the failure of the former was largely due to the fact that an excess of carbon dioxide could not be maintained because of its slight solubility and slow absorption in water. An excess of barium peroxide, even if local, will cause decomposition and loss of hydrogen peroxide as shown by the reaction

$$H_2O_2 + BaO_2 = Ba(OH)_2 + O_2$$

It seemed reasonable to expect that if barium peroxide were slowly added to a solution of carbon dioxide which was maintained at a relatively high concentration by means of an atmosphere of carbon dioxide under high pressure, a condition analogous to that in the usual method would then exist and good results be obtained.

We were unable to devise an experimental apparatus which would accomplish the above-mentioned conditions without involving a greater expense than would be permitted. The difficulty lay in the problem of slowly feeding the barium dioxide into a chamber having a high internal gas pressure. So we decided to see what results could be obtained by treating an emulsion of BaO_2 (barium peroxide) and water to a high pressure of carbon dioxide gas. To this end we made a reaction chamber of pipe fittings consisting of a 2-in. sleeve closed at one end by a cap and connected at the other end by means of a bushing and a ¼-in. pipe to a cylinder of carbon dioxide. The chamber was charged with an emulsion of barium dioxide and water, tightly closed, cooled to 4 deg. C. by an ice pack, connected to the cylinder of carbon dioxide and the pressure turned on to 80 lb. pressure for 20 minutes, during which time the reaction chamber was kept agitated in order to facilitate the rapid absorption of carbon dioxide.

The completion of the reaction can be judged by the fact that during the reaction carbon dioxide must be continuously supplied in order to maintain the pressure, but when the reaction is completed the pressure will remain constant without such addition. The pressure was then released, the reaction chamber opened, the charge quickly filtered and tested to determine the percentage of hydrogen peroxide recovered. This was calculated as follows:

A weighed portion of barium peroxide in a measured quantity of water will give a hydrogen peroxide solution of definite strength if perfectly converted. The ratio of the actual strength (as determined by titration with permanganate) to the theoretical strength gives the percentage recovery. A large number of such tests were made with various conditions of time, pressure, amount of charge, etc. The results ranged from 50 to 80 per cent recovery. They indicated that the carbon dioxide was absorbed as rapidly as the barium peroxide could dissolve, thus maintaining an acid condition even in the presence of an excess of barium peroxide.

The Commercial Unit

These results were so encouraging that it was decided to proceed at once to an apparatus of commercial size, as the problem of feeding the barium peroxide into the reaction chamber could be worked out more easily than in a smaller device. A 6 x 6-ft. vertical cylindrical iron tank was provided with a mechanical stirrer, a false bottom of canvas filter cloth supported by a wooden frame, and an outlet pipe with valve under the false bottom. Access to the interior was obtained by a manhole having a tightly fitting cover. Valve-controlled inlets for compressed air, carbon dioxide and barium peroxide emulsion were provided, also pressure gage, small outlet cock for taking samples and a thermometer well.

Our most difficult problem was to introduce the barium peroxide into the pressure tank, and we tried a number of different pumps without success. We also tried to feed the barium peroxide as a dry powder through a cock in which a rotating plug provided with a small depression or pocket was substituted for the ordinary plug having an opening clear through it. It was hoped that as the plug rotated the barium peroxide

would fall from the hopper above into the depression in the plug and be carried around and dropped into the reaction chamber. The device failed because it was impossible to prevent excessive leakage of gas and also because the barium peroxide powder refused to drop consistently into and out of the pocket of the rotating plug, due to its cohesive nature.

We also made an emulsion of barium peroxide with water and tried to pump it into the reaction chamber with several different types of pumps. None of these pumps could be kept in operation for any length of time due to the tendency of the barium peroxide to settle out in the valves and thus prevent them from operating. These deposits would set into a hard cement, and this tendency was increased by any carbon dioxide which might force its way back into the pump system.

Solution of Feeding Problem

This difficulty was never completely overcome, but we finally devised a simple single-stroke plunger pump using ordinary brass check valves, which operated fairly well and could be cleaned easily and quickly when necessary. I believe that a more satisfactory method would be to emulsify the barium peroxide in a small auxiliary pressure tank and permit it to run by gravity into the reaction chamber after equalizing the pressure in the two. It would be necessary to use some other means than a direct application of the carbon dioxide atmosphere for equalizing the pressure, because reaction would then take place in the emulsion chamber and the hydrogen peroxide formed would be destroyed by the excess of barium peroxide.

Our procedure was as follows: A mixture of about equal weights of ice and water was put into the reaction vessel, all openings closed, the agitator put in operation and carbon dioxide admitted to about 60 lb. pressure.

A 100-lb. batch of barium peroxide emulsified in 200-lb. ice water was prepared in a small mixing tank and pumped into the reaction tank at a rate which required from 2 to 3 hours to handle four batches, a complete run. From time to time samples were withdrawn and tested for percentage of acidity, and the pump speed and carbon dioxide pressure were regulated accordingly. We found that the best results were obtained at about 0.2 normal acidity, alkalinity and high acidity both causing decomposition and loss of hydrogen peroxide.

Irregular action and sometimes complete failure of the pump caused by barium peroxide settling in the valves and pipes frequently caused the acidity to fluctuate to a dangerous degree. Decomposition would then commence and the additional heat thereby generated would consume the ice. This condition would be indicated by a rise in temperature, and it was then necessary to filter the charge as quickly as possible in order to prevent a total loss.

The decomposition of H_2O_2 in alkaline solution could be accounted for as explained above, but we were doubtful concerning the reason for the harmful effect of high acidity. One theory advanced was that iron from the apparatus was brought into solution, causing catalytic decomposition. An interesting fact is that the barium carbonate precipitate was granular when formed at the proper acidity, but flocculent when either high acidity or alkalinity existed.

Yields Obtained on Large Unit

Our average recoveries were low, 80 to 85 per cent, which was due mostly to faulty mechanical and thermal control. On several runs we obtained recoveries as high as 95 per cent, which compares favorably with those obtained by the usual method on the same grade of barium dioxide. We were treating the lower grade of our barium peroxide production and we later heard that the Eastern manufacturers who purchased the bulk of our supply obtained very poor extractions on certain lots. Slow filtration also accounts for considerable of our losses in many instances.

After filtering the charge, the barium carbonate was washed several times with water and the washings were used as an initial solution for the next run. The main filtrate still contained some barium in solution as bicarbonate, most of which was precipitated with sulphuric acid. The final trace of barium was precipitated with phosphoric acid, a slight excess being used. After again filtering, the hydrogen peroxide solution was run to storage tanks and air bubbled through it to remove carbon dioxide.

Baffling Instability: "The Home Brew Problem."

The hydrogen peroxide so produced conformed to all the tests required by the trade, both as to purity and stability. Some impurities commonly introduced by the mineral acids were completely absent, and we found no other brand which excelled in purity. For several months it was put on the market with complete confidence in the belief that it was of superior quality. Then reports of disaster began to arrive. I use the word report advisedly, because a considerable portion of our product decomposed and the pressure of the liberated oxygen blew the corks out of the bottles.

It was a very baffling situation. Our chemical tests revealed no impurities which could cause the trouble, and most baffling of all was the fact that samples which gave a satisfactory stability test were not stable. The stability test consists in heating a flask of hydrogen peroxide on a water bath and measuring the rate of decomposition at definite temperatures. The presence of percarbonic acid, which would be destroyed during the first stage of the stability test, might account for the facts. Another theory is that minute traces of metal from the apparatus were held in solution, but the cause has never been definitely proved. We kept samples of each run and many of the samples showed no appreciable loss after many months, so we concluded that the cause of instability could not be an inherent factor of the method.

Market conditions caused us to discontinue the manufacture of hydrogen peroxide before the question of stability was solved. It is the writer's opinion that enameled ware equipment designed to give good mechanical and thermal control would solve the problem of stability both during and after manufacture, and that the process is superior to present methods.

Texas Leads in Oil Refining

The extent of the growth of the refining end of the petroleum industry in Texas is shown by the fact that there are now 109 oil refineries in the state, 63 of which are on the active producing list at the present time, with aggregate production of 345,150 bbl. per day. In addition, there are 9 refineries in course of construction. Texas now stands as the leading state of the Union in this branch of the industry, and is third in point of production of crude petroleum, with a record of 105,209,500 bbl. in 1921.

Some Causes of Rejections in Boiler Tubes

By H. G. Carter

IN THE manufacture of boiler tubes very low-carbon solid round billets are charged into a furnace and heated to a good forging temperature, which is in the vicinity of 2,100 deg. F. Upon being brought to the proper heat the billets are put into a piercing machine, where the center is punched out, the solid billets being thus converted into rough seamless tubes. These tubes are permitted to cool (usually by permitting them to roll into a tank of water) and sent to a pickling room, where the scale is removed, after which they are taken to a draw-bench and the ends tapered for a "tong hold." They are then drawn through a die and over a mandrel or plug. This process is repeated until the desired outside diameter and wall thickness is obtained, the tubes being given several process annealings and picklings during the drawing operations. When the desired size has been reached, the tubes are given a final annealing, straightened, cut to length and presented for inspection and testing.

Tubes are rejected chiefly on account of the following defects: crookedness, non-uniformity of wall thickness, seams, tears, excessive scale and brittleness as shown by expanding, flattening or hydraulic pressure tests.

FIGS. 1 TO 4—STRUCTURE OF DEFECTIVE BOILER TUBE

Fig. 1—Coarse grain. Etched with HNO_3. × 60

Fig. 2—Burned steel. Unetched. × 30

Fig. 3—Lap seam. Etched with HNO_3. × 60

Fig. 4—Crack following dirt string. Unetched. × 60

Rejections due to crookedness and brittleness are usually temporary, because crooked tubes are put through a straightening machine and the brittle ones reannealed and both returned for inspection.

Tubes that are rejected because of non-uniformity of wall thickness are redrawn to make tubes of a smaller size and after annealing and straightening are submitted for inspection.

Tubes with seams and tears are absolutely rejected and are either scrapped or sold for low-grade tubing for uses such as electrical conduits.

Let us look into the cause of some of these rejections.

Brittleness is usually the result of large grains caused by overheating during the annealing, which is the result of carelessness on the part of the furnace man or is caused by poor furnaces of improper design or by faulty pyrometers. Fig. 1 shows a structure which failed the expanding and flattening tests due to excessive grain size, but was salvaged by reannealing, which produced a much finer structure.

Another cause of brittleness not usually discovered in the inspection department is due to burnt steel, a defect which generally appears in the piercing machine or at the draw-bench. Burning can usually be traced to the heating for piercing. Fig. 2 shows an extreme example of burnt steel; here the grain boundaries have opened and are lined with iron oxide. Other examples of burnt steel have been observed, not sufficient to oxidize the grain boundaries to a visible extent, but the billet was nevertheless so brittle that drawing was impossible. Of course burning may take place in the steel mill, but this does not usually happen.

Lap seams are the usual type found in seamless tubes and are caused by folding excess metal over upon itself during the first pass in the drawing process, which is subsequently drawn down to a thin fold but not united to the metal beneath it. Fig. 3 shows such a seam.

Tears occurring during the drawing process and cracks resulting from hydraulic tests are usually traceable to dirt chains and ghost streaks. Fig. 4 shows a crack from a fracture following a dirt chain. Cracks often follow a ghost streak (band of metal which remains bright after etching with Stead's reagent). Excessive dirt in steel is usually found to be located within these ghost streaks.

Rejections due to crookedness, non-uniformity of wall thickness, excessive scaling, brittleness caused by overheating in annealing and burnt steel (excepting steel burnt at the steel mill) are preventable, unnecessary and constitute a very large part of the total rejections. They are the result of carelessness, incompetency or the lack of intelligent supervision of those in charge of the departments in which they originate.

Rejections caused by dirt, gas holes, ghosts, segregations and burning at the mill may be classified as unavoidable rejections, except that they can be greatly reduced by purchasing a good grade of steel and by making a complete trial run of a few bars before starting the entire shipment through the mill.

Waverly, Mass.

The Katathermometer

The katathermometer is an instrument contrived by Dr. Leonard Hill, an eminent English physiologist. Dr. Hill, after exhaustive experiments, concluded that the rate of cooling of the human body was the controlling factor in determining comfort or discomfort. The katathermometer measures the rate of cooling of the body. A preliminary study by the Bureau of Mines indicates that the instrument will be useful for making determinations of comfort conditions in coal and metal mines.

Handling the Finished Products of Industry—III

General Consideration of Soap Manufacture—Why It Is Profitable to Use Mechanical Methods in Handling Finished Soap—Two Examples From Existing Soap Factories, Showing Amount of Non-Productive Labor Eliminated in Each Case*

By GRAHAM L. MONTGOMERY

HANDLING the finished product—from the time the last true manufacturing process is completed until the article passes out of the ownership of the maker—often costs more than all the other charges which the work must bear, as pointed out in the first article of this series. This is particularly true in an industry where the process of manufacture is one entailing but little labor, an industry essentially adapted to production in bulk. In such an industry the operations necessary to prepare the finished product for the market are the operations entailing most of the non-productive labor and are responsible for most of the labor cost which enters into the sale price. The reduction of the cost of this non-productive labor therefore presents the possibility of increase in profits or reduced selling price. As an illustration of such an industry and an example of the steps which can be taken toward cutting down the non-productive labor, let us consider the manufacture of soap and its preparation for the market.

Soap Manufacture

Soap making is an ancient art. During the many centuries of the development of this art a routine of manufacture has been established which eliminates all unnecessary labor during the process. Whatever the type of soap manufactured, be it soft or hard soap—cold or hot process—the material flows from step to step by gravity or pump. The function of labor has been reduced to the control of the process and there is little possibility that much more reduction in labor can be brought about.

In handling the raw material, the field for economies is again small. Today this raw material is largely liquid and its handling is extremely simple and inexpensive. In case a hard fat forms the basis of manufacture, it is first melted and can then be handled as an oil would be. The savings possible in this part of the work are at best slight, so slight that their study promises little immediate reward.

The last operation in the manufacture of the soap leaves it in the large block in which it has set in the frame. A number of these blocks are shown in the accompanying illustration. As these blocks stand, they are finished soap and no further changes need be made in their constitution. But they are not in marketable form. They must be made into cakes of a size suitable to the uses and the buying habits of the consumers who will ultimately purchase them. Other operations that must be gone through—depending on the quality and use of the soap—are: marking with suitable name or trade mark, wrapping and packing in boxes, cartons, or cases.

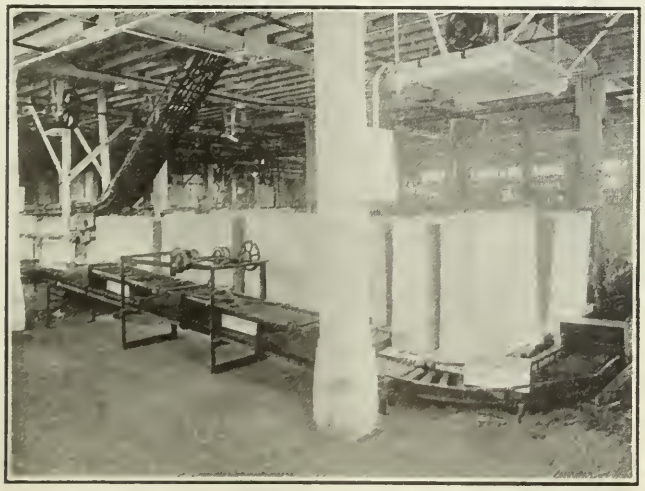
Preparing Soap for the Market

The first operation performed in preparing soap for the market is to cut the blocks mentioned above into slabs. This is done by forcing the block through a frame in which are a number of vertically strung wires. The spaces between these wires determine the thickness of the slabs. After the slabs are formed they are put through the cutting machine. Sometimes this machine only cuts the slabs into strips and then these strips have to be put through another cutting machine which cuts them into bricks of soap of a proper size to form the desired cake. Usually these two cutting operations are done on one machine, the slab being forced through the strip-cutting wires and then all the strips together being moved at right angles through the brick-cutting wires.

The bricks of soap resulting from the last operation are placed next in the press. This takes each brick separately and presses it into the desired cake-form. At the same time the names, trade marks, ornamental designs or other devices are imprinted on its surfaces. Some grades of soap contain too much moisture when in the brick form and it is necessary to dry or cure them before they reach the press. If space is available and cheap, this can well be done by the atmosphere in any well-ventilated and dry room. It is, however, more usual to place the soap bricks in drying rooms, where the drying is expedited and kept under control through the use of artificial heat.

After the cakes leave the press, the next operation generally consists of placing the wrapper on them. This is now usually done in automatic machines, although in some cases where the cake is of a fancy shape it is still customary to do the wrapping by hand. From the

*Article I of this series appeared in Chem. & Met. Eng., vol. 26, No. 18, p. 823, May 3, 1922. Article II appeared in vol. 26, No. 19, p. 885, May 10, 1922.



BLOCKS OF SOAP FROM FRAMES WAITING TO GO THROUGH SLABBER

wrapping department, the soap passes to the packing tables. Here it is packed in some sort of container, depending on the quality of the soap and how it is marketed.

Labor Used in Preparing Soap for Marketing

The routine of preparation described above is not the only one used and various manufacturers follow different methods, according to the kind of soap they make and the requirements of their market. It is, however, general enough to serve as a pattern, any variations which occur being easily interpreted in the above terms.

The labor used in these operations consists of that needed to perform the actual cutting, pressing, wrapping and packing; and that used in moving the soap from operation to operation. Of the former, it is safe to consider the cutting and pressing as productive, since these two processes actually enhance the market value of the soap. The wrapping and packing, together with all the handling, are non-productive.

As stated above, there is little opportunity to cut down the productive labor in soap making. The use of automatic machinery for cutting and pressing is quite general. In the exceptional cases where machines are not employed for this work, it is possible to effect a considerable labor saving by adopting these machines. And in almost all cases where drying rooms are employed between these two operations there is handling in connection with these rooms which could easily be eliminated. That, however, actually comes under the non-productive classification.

The non-productive labor in soap making is, as we have seen, almost entirely confined to that expended in handling the finished soap. Of late years there has been a creditable introduction of automatic wrapping machinery and some plants have also installed more or less complete mechanical handling equipment from the presses onward to the packing tables. The following two examples from actual working installations will serve to show what has been accomplished to date and perhaps point the way to a more complete realization of the savings to be obtained from such improvements.

Before passing to these examples it is well to point out that no attempt is here made to criticise the manufacturing methods in vogue throughout the soap industry. It is no doubt possible that improvements which will lessen the cost of this manufacture can and will be effected as time goes on. But while the present processes and methods hold their favored place with manufacturers, and assuming no immediate, decided drop in cost of raw materials or fixed charges, it is to the reduction of the non-productive labor cost to which we must look for lowered production costs and increased efficiency.

A Plant for Making Cheap Soap in Large Amounts

Let us take for consideration first a plant where the total bulk of product is large—where the product, while divided into two or three grades, is really all about the same, and where the selling price must, in accordance with the nature of the product, be low. In the first place, in making soaps of these grades, the methods employed by all manufacturers in the actual manufacture are essentially the same. The raw materials will in most cases be obtained by all the competitors at about the same price. The amount of labor is about the same for any of these plants, diminishing proportionately per ton output as this output increases. This fact makes it desirable for every manufacturer to increase the bulk of his sales and hence the relative output per unit of productive labor cost in order to compete with others in the field. However, most of the producers have sufficient bulk of product to meet this condition successfully and if they desire to reduce their total production costs so that they may increase their profits or lower their prices they must look to some other means. A number of plants of this type have found the solution in the almost complete adoption of mechanical equipment for the handling and forming of the soap between the point where the frame is stripped and that where the soap is loaded out of the plant.

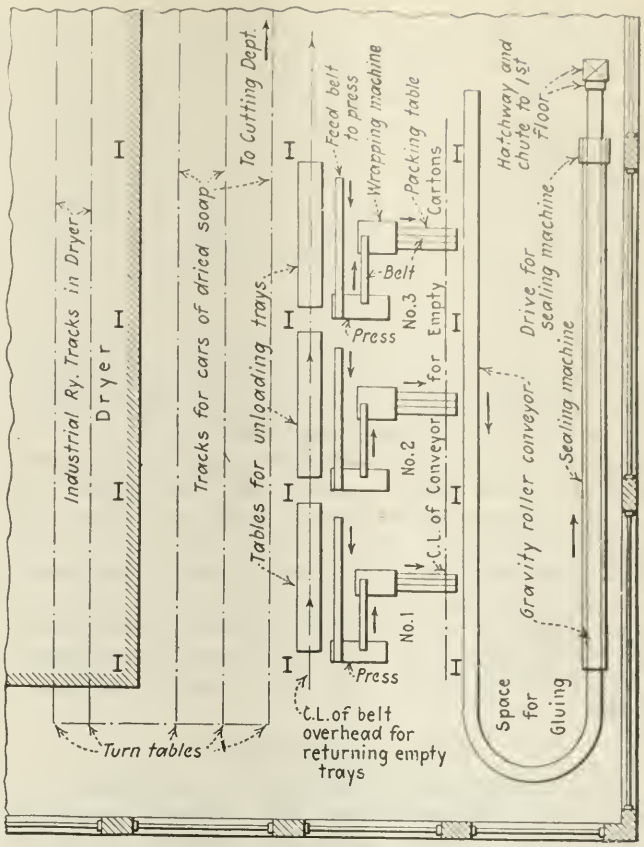


FIG. 1—PLAN OF HANDLING IN PRESSING, WRAPPING AND PACKING DEPARTMENTS

The sketch marked Fig. 1 shows a part of one of the most complete installations of this type of equipment so far put in. Here the blocks of soap from the frames, shown in one of the accompanying illustrations as standing on the wheeled bottom of the frame after the frame-sides have been removed, are put through a slabbing machine. This cuts the blocks into slabs having the cross-sectional dimensions of the original block for length and breadth and thickness enough to meet the requirements of the finished cake. The slabs are then put through the cutting machine, which, automatically in two cuts, produces bricks of soap of the proper size to be pressed into the finished cakes.

These bricks are placed by hand on slatted wooden trays as they come out of the cutter, about 100 bricks to the tray. The filled trays are stacked ten high on wooden platform industrial railway cars, making 1,000 cakes per car. After a car receives its full load of trays, it is pushed down the track and into the drier. Here the soap is dried sufficiently so that it is stiff enough for pressure into the desired cakes.

On leaving the drier, the carful of trays of soap bricks is taken by means of the turntables in the industrial railway to one of the tracks marked for this purpose on Fig. 1. The trays are removed and piled upon the adjacent tables. Between each of these tables and the belts marked "Feed Belt to Press" stands a worker whose function it is to remove the cakes from the trays and place them one at a time on the press feed belt. When a tray is emptied, it is placed on the overhead belt conveyor and returned to the cutting machines to be refilled.

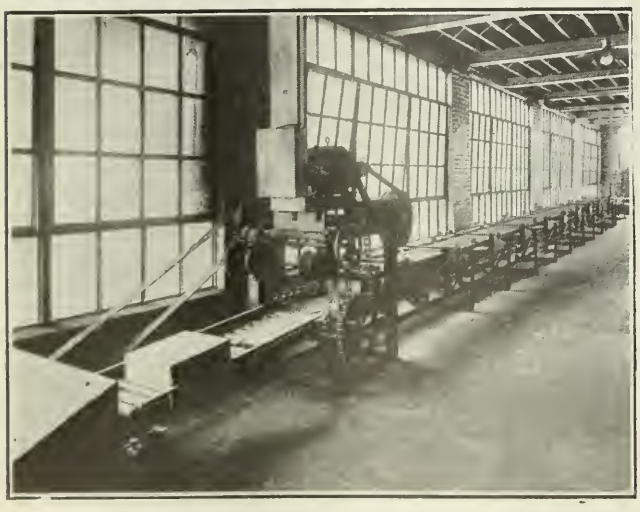
The soap bricks on the press feed belt are automatically fed one by one into the press. This press takes each cake and presses it into the shape desired for the finished cake, at the same time imprinting on the sides of the cake the desired name, trade mark, etc. After this pressing is completed, the cake is automatically discharged to a second belt. This second belt conveys the cake to the wrapping machine. Here the cake is wrapped and passes onto a third belt, which runs down the center of the packing table. On either side of these tables the packers stand and place the cakes of soap in paper cartons as they take them off the belt. The empty cartons are fed in on a gravity roller conveyor which passes over these packing tables, as shown on Fig. 1.

Sealing the Cartons

After the cartons are filled they are placed, open side up, on the U-shaped gravity roller conveyor shown in Fig. 1. This conveyor takes the cartons to the point marked "Space for Gluing." Here the flaps of the carton are glued down and the carton is turned over, so that its own weight, pressing it down against the conveyor, tends to seal it. In this way it enters the sealing machine, shown in the accompanying illustration. This machine forces the carton to pass between upper and lower sets of rollers, which exert sufficient pressure to seal it effectually. After passing out of this machine the carton is delivered by gravity conveyor to an inclined conveyor of the push-bar type, which delivers the cartons to the car-loading and storage system of gravity conveyors on the floor below.

Loading by Conveyors

This system of gravity conveyors, shown on Fig. 2, is so arranged that three cars may be loaded at the same time, the cartons coming either direct from the packing department above or from any one of the storage spaces shown on the figure. This is accomplished by means of an ingenious arrangement of switches. The end sections, which extend into the cars when they are being loaded, can be raised out of the way when not in use so that the track is free for movement of cars. The loading platform, with three cars in position for loading, is shown in the accompanying illustration.



SEALING MACHINE AND CONVEYOR TO FIRST FLOOR

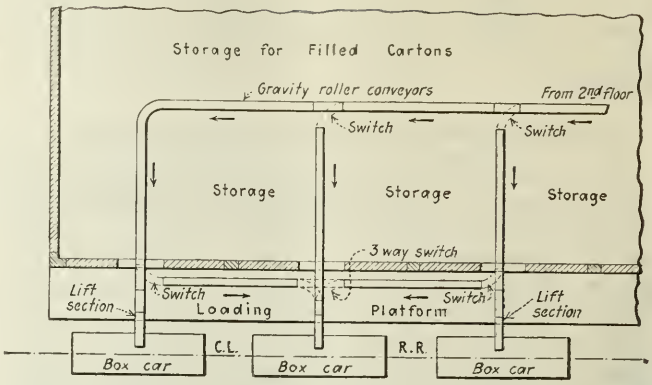


FIG. 2—LOADING CONVEYOR SYSTEM

A Plant for Making Expensive Soaps in Large Variety

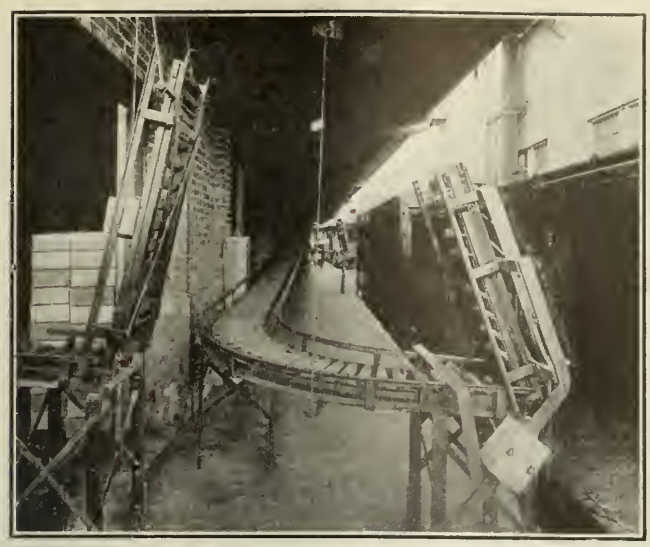
The second example is a plant for the manufacture of toilet and other similar grades of soap. In the particular plant in question the soap is packed in two ways. That for the general market is pressed into oval cakes bearing the trade name on one side and the manufacturer's name on the other. Each of these cakes is then wrapped in a fancy wrapper. After wrapping, three cakes are placed in a fancy pasteboard box and these boxes are in turn placed in paper cartons or wooden boxes for shipment.

Soaps to be shipped from this plant to South America are cut into bars only. The name and trade mark are pressed into these bars, which are then packed in paper-lined wooden cases of heavy construction, holding 100 bars each. The difference in packing methods is due to the fact that South American shipments undergo particularly rough treatment and precautions must be taken to prevent damage to the soap.

It will be noticed that the soap made in this plant is not put through a drying room between the cutting and pressing. This is because of the manufacturing methods used by the plant, the moisture content of the soap from the frames being right without further drying.

How the Soap Is Handled

Fig. 3 shows the layout of the departments where the finished soap is handled in this plant. The soap which is shipped abroad in the heavy cases is adapted to an extremely simple handling routine. The slabs are brought from the fourth floor to the fifth floor in the elevator shown on Fig. 3 on hand trucks and transferred by hand from these to the cutting machines. The packers stand at the discharge of the cutting machines and as the bars come from the machines, place them in cases which are standing on one of the roller conveyors adjacent. When a case is filled, it is shoved to the end of the conveyor and at this point the cover is fastened on. As fast as the last operation is finished, the boxes are transferred to the gravity conveyor which runs at right angles to those mentioned above. This last conveyor takes the case to the large spiral chute



LOADING PLATFORM AND CONVEYOR

shown on the outside of the building. The cases go down this chute directly into the shipping department.

Handling Fancy Toilet Soaps

The toilet soaps are delivered to the fifth floor in slabs as described above and are transferred from the elevator to the department where they are cut—shown in Fig. 3—on hand trucks. After being cut and pressed into the desired cake form, the cakes are loaded into wheeled transfer boxes and pushed over to the row of twelve packing tables shown.

These soaps are packed, three or more per box, in fancy paper boxes. When the boxes are filled and closed, the packers place them one by one on the gravity conveyors which run between the ends of the packing table and the wall toward the small spiral chute leading to the third floor. These boxes run by gravity down the conveyor to this chute and down the chute to the table marked "Receiving Table" on the third floor.

At this receiving table, the small boxes are placed either in paper cartons or wooden cases depending on where and how they are to be shipped. These cartons and boxes when filled weigh about 200 lb. each. When they are filled and sealed or covered, they run down a gravity roller conveyor which leads from the receiving table to the large outside spiral chute. Then they run down this chute to the shipping department.

The Shipping Department

The foot of the large spiral chute is situated in a one-story building which serves for a shipping department. The outlet of the chute discharges onto a roller conveyor of slight inclination, which serves for distributing the cases and cartons to storage areas or for delivering them to truck or freight car as desired. Due to the slight inclination of this conveyor, the packages move only when slightly pushed. This serves to keep them at rest while they are marked or labeled.

Labor Saved in First Plant Cited

In the first example given the labor employed from the point where the soap is in the frame up to the point where it is unloaded from the tray to the press is the same as if there were no labor-saving devices employed in the plant. Beyond this point the labor used is as follows: One worker to remove soap bricks from trays and place them on press feed belts, making three in all. Two workers at each packing table, making six in all. One worker for gluing cartons. Three men on loading platform. Total workers now employed for work in question is thirteen.

Before the labor-saving machinery was installed the labor required was as follows: One worker unloading trays at each press, making three in all. One worker feeding each press, making three in all. One worker feeding each wrapping machine from discharge of press, making three in all. Two workers packing at discharge of each wrapping machine, making six in all. One worker gluing cartons. Six workers trucking sealed cartons from second floor to storage and shipping on first floor. Six workers on first floor loading cars. Total workers formerly employed, twenty-eight.

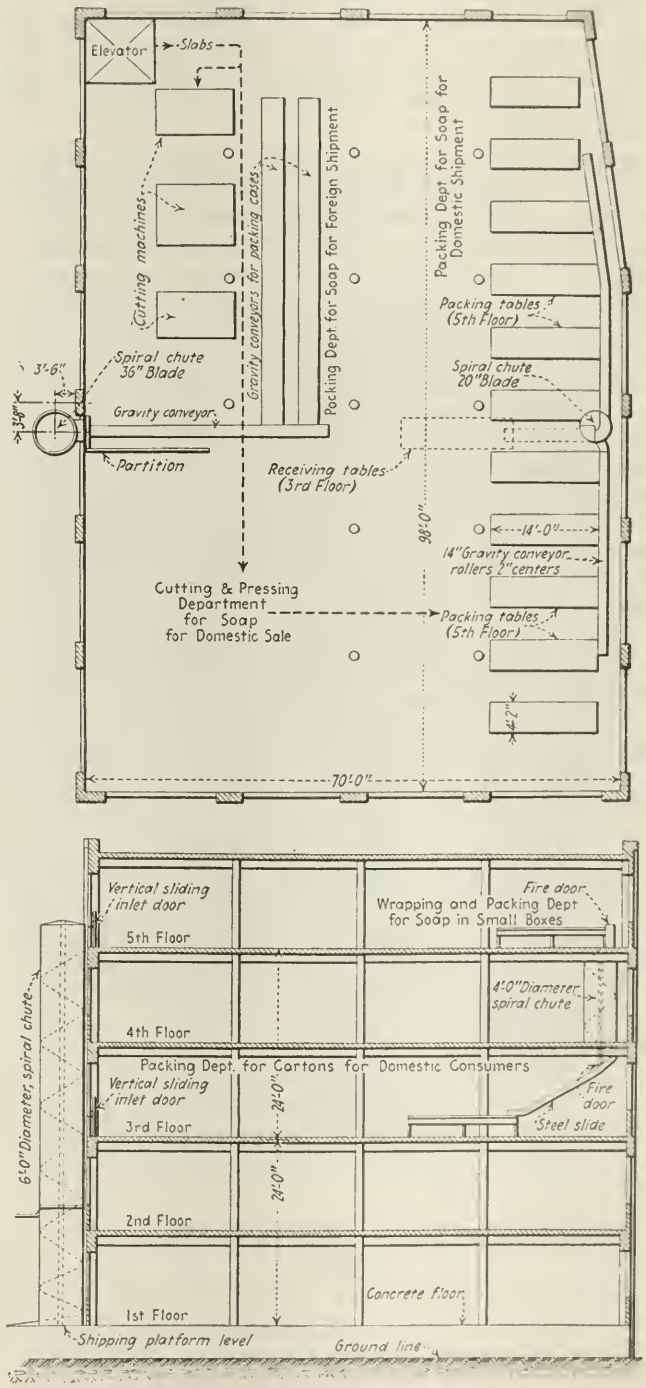


FIG. 3—PACKING DEPARTMENT AND CONVEYORS FOR FINE SOAP FACTORY

The saving, then, in labor due to the installation of labor-saving machinery in this plant was fifteen men, or 54 per cent. Since this type of work requires workers of the same pay-rate throughout, we can safely say that a saving of 54 per cent of this labor cost was effected. As the workers on the press and wrapping machines and at the packing tables were enabled to turn out a larger product than formerly, the actual returns of the new equipment were even greater than this 54 per cent.

Labor Saved in Second Plant Cited

In the second example given the labor must be analyzed in three parts: First, that where the soap is packed for shipment to South America. Second, that where the soap is packed for ordinary shipment. Third, the labor saved in the shipping department.

In the first division of this work the same number of men is used for packing and closing the cases as formerly, this number being five. The men used to truck the cases to the elevator, two in number, are no longer employed.

In the second division the workers employed at the cutting, pressing and packing work and for handling the soap between these processes remains as before, the number being twenty-two. From the packing department to the shipping room there are no workers used, where formerly six were employed.

In the third division, the shipping department, two men are now employed, one to place boxes on the conveyor, the other meanwhile unloading them in truck or car; or one to label and tag, while the other removes boxes from the conveyor. Formerly, for unloading from the elevator with hand trucks and wheeling the boxes to the various required points, six men were needed to handle the same volume of product in the same time. This gives us a saving of four workers in this division of the work.

To recapitulate, the plant now employs twenty-nine workers on this labor where it formerly employed forty-one, so that the saving amounts to 29 per cent. As in the first plant, more volume of product can now be turned out in the same time, so that this 29 per cent does not represent all the advantage made possible through the material handling equipment that was installed.

Conclusions

From the examples which have been cited above, it is evident that the more complete the handling system used the larger is the percentage of the non-productive labor that can be eliminated, provided all other influencing conditions remain the same.

It is also evident that, taking no account of increased production through elimination of confusion and through speeding up of work, savings made through a lowered labor turnover, and the decrease in the management burden, material handling equipment in many cases pays well by the non-productive labor it eliminates alone.

The writer desires to express his appreciation of the kindnesses extended to him by The Dow Co., of Louisville, Ky., the manufacturer of the conveying equipment described in this article. The data which form the basis of this discussion and the photographs and drawings used for illustrating were made available by The Dow Co., and The Dunning & Lueckel Engineering Co., of New York City.

Commercial Production of Mucic Acid

Mucic acid [$(OH)_4C_4H_4(CO_2H)_2$] is one of the most recent of the rare organic chemicals to become available on a large commercial scale. It is being produced at Eureka, Mont., by a process patented by Professor Acree of Harvard University and worked out on a plant scale by the International Chemical Products Co., of Baltimore, Md. The process consists in the hydrolysis and oxidation of mixtures of glucose and galactose obtained from the species *Larix occidentalis*, which is commonly known as Western larch. Oxalic and other organic acids are obtained as byproducts.

Some idea of the extent of operations can be obtained from the statement that the Montana plant covers 20 acres and has an annual output of approximately 600 tons of mucic acid. The production has been almost entirely sold to the manufacturers of self-rising flour. The cost of the product is said to be considerably less than that of citric acid or cream of tartar and when its higher neutralizing strength is considered, it is entirely comparable with the cost of high-grade phosphates.

Mucic acid is a white crystalline or powdered material, without water or crystallization. It is readily assimulated in the metabolism of the human body,[1] probably due to the fact that it is a partly oxidized carbohydrate. Most of this company's output is of the chemically pure grade, but a small amount of the technical product has been sold for use in the dyeing of textiles, where it acts as a mordant and fixing agent in the place of cream of tartar. Mucic acid is marketed under the trade name "Cream of Milk Sugar."

The principal use of mucic acid at present is as a baking acid in the self-rising flour industry. It is claimed that its insolubility in the cold enables it to be kept in a baking mixture almost indefinitely without releasing leavening gas. This property is also of value in connection with its use in baking powders. Samples of baking powders containing mucic acid have been kept in incubators saturated with water vapor and at the end of a test of 14 months showed losses of less than 2 to 3 per cent of available carbon dioxide. Theoretically, pure mucic acid will neutralize 80 parts of pure sodium bicarbonate as against 75 parts and 45.6 parts in the case of monocalcium phosphate and cream of tartar respectively. The use as a mordant and chrome assistant in the dyeing of textiles has already been mentioned. It is also believed that the pure acid will be comparative with citric acid in the preparation of effervescent salts, soft drinks, ice cream and other food products.

New Alcohol Mixture for Motor Fuel

Tests recently completed by the Sociedad Nacional de Agricultura of Rio de Janeiro, Brazil, indicate that a satisfactory fuel can be produced at a cost which compares favorably with gasoline. The selling price of alcohol at the Campos sugar mills in Brazil is about 27 cents per gal., while the price of gasoline in Rio de Janeiro is about 75 cents per gal. The alcohol is made from sugar cane residue, at present thrown away because of lack of transportation facilities.

The best results were obtained from a mixture composed of 65 parts alcohol, 25 parts ether, 9.5 parts kerosene and 0.5 part pyridine. The consumption of a heavy Benz car during the test was 98.5 c.c. per kilometric ton of weight, while the consumption of a light 1American car was 126 c.c. of gasoline per kilometric ton.

Corrosion of Petroleum Refining Equipment*

By R. R. Matthews and P. A. Crosby

In earlier papers which have been published in this magazine[1] we have shown that in refining mid-continent petroleum in a so-called pipe still hydrochloric acid is formed as result of the hydrolysis of the magnesium chloride in the brine associated with the petroleum. This caused rapid corrosion wherever the acid vapors condensed, and in consequence increased costs of maintenance. As a preventive measure ammonia was introduced into the vapor system; first the anhydrous was used and later aqua ammonia. This reduced the corrosion and lengthened the life of the apparatus—especially of the condensers. It is true that corrosion may also be caused by dissolved gases, such as hydrogen sulphide, oxygen and carbon dioxide, but hydrochloric acid is only the corrosive agent whose cause and effect have been studied here.

In the present paper further evidence is offered of the corrosion caused by hydrochloric acid produced in refining petroleum, and it is shown that this corrosion is not confined to refineries using the pipe still, but is also noted in installations where shell stills are used.

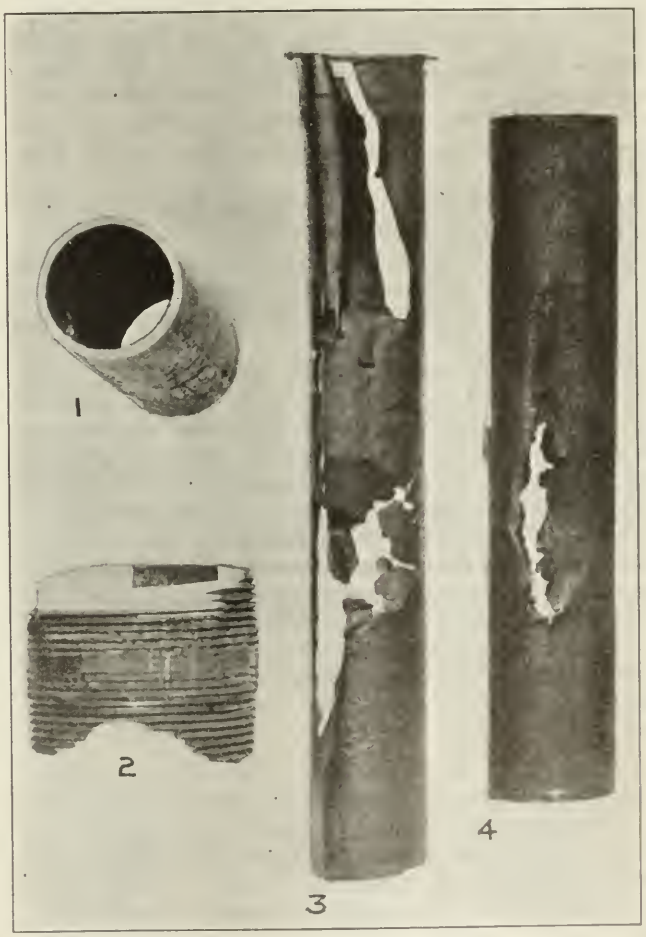
In this particular case eight stills had been set up for continuous operation—that is, the oil flowed from one still to another, each successive still being held at a higher temperature so that by the time the eighth still was reached the finished residual product could be drawn off. Each still was equipped with a dephlegmator and the necessary condensers and coolers, the latter being of the tubular type. The stills were also equipped so steam could be used in the bottoms of them.

This bench of stills has been operated only periodically since completion with, say, a month's operation and then several months' idleness. After about 2½ years it was noted that some of the tubes in the condenser used with No. 4 still were leaking. The next time the bench was not in operation the leaking tubes were replaced. Examination of the tubes removed showed that the top portion, where the vapor entered, had been corroded for about 18 in. on the oil side until the metal was very thin. This was the same sort of hydrochloric acid corrosion which had previously been observed in the pipe stills, although it had been felt that such trouble might be avoided in the shell stills because considerable salt water would settle from the crude oil in the first still and could be drawn off. Furthermore, the remainder of the brine would be dehydrated in the next still and the salts pass with the oil through the other stills, causing no trouble.

In order to investigate this point in the laboratory, crystalline magnesium chloride was added to water-free oil and then heated up slowly in a distillation flask. Hydrochloric acid vapors began to come over shortly after reaching a temperature of 175 deg. C. (347 deg. F.), and considerably more were noted when the temperature was brought up to 200 deg. C. (392 deg. F.). This showed that the water of crystallization in the crystalline magnesium chloride is sufficient for the hydrolysis. Of course, the brine in the oil consists largely of sodium chloride, and, even though concentrated considerably, or reduced to crystalline form in passing through the first stills, there would probably be but little acid liberated at first because of the relatively small proportion of magnesium chloride. As the oil reached the hotter stills, rapid hydrolysis would result. The laboratory results show that when such stills were reached, acid would be produced and carried over with the oil vapors. The result of the latest tests indicates that this hydrolysis takes place most vigorously at temperatures above 150 deg. C. (302 deg. F.); and that sodium and calcium chlorides apparently do not enter into the reaction.

Conditions in No. 4 still were extremely favorable for this hydrolysis of $MgCl_2$. The temperatures of the oil in this still were found to fluctuate between 177 deg. C. (350 deg. F.) to 243 deg. C. (470 deg. F.) during the time the stills had been operated, and this temperature, aided by the fact that superheated steam was being used, undoubtedly resulted in the formation of hydrochloric acid vapors, which were carried over until they struck the cold tubes of the condenser. The condensation there, of course, meant action on the tubes and eventually reduced them to the paper-like thinness which was noted when they were removed.

Later it was also found necessary to change the tubes



FIGS. 1 TO 4—EXAMPLES OF CORRODED PETROLEUM REFINERY EQUIPMENT

Fig. 2—A short nipple showing how threads on pipes were corroded away.

Fig. 3—A piece of one of the corroded tubes removed from a condenser at the bench of eight stills.

Fig. 4—A portion of the tube taken from the heat exchanger, showing the place where it gave way.

*A paper read before the Petroleum Section of the American Chemical Society at Birmingham, Ala., April 5, 1922.

[1]Chem. & Met. Eng., vol. 22, No. 11, p. 491 (March 17, 1920), and vol. 23, No. 23, p. 1122 (Dec. 8, 1920).

in the condenser on No. 5 still. Temperatures there were found to have ranged from 182 deg. C. (360 deg. F.) to 260 deg. C. (500 deg. F.). The condensers on the four other stills have not yet caused trouble, so it seems likely that the most of the hydrochloric acid is liberated in the temperature range from 175 deg. C. to 250 deg. C. Michael Freund,[2] in experiments with Russian petroleum, also found that these temperatures and conditions were most conducive of this type of corrosion.

Other refiners of our acquaintance have also noted this acid formation, but it appears to cause more serious corrosion where steam is used in the stills. No doubt the steam does assist somewhat in the hydrolysis of the magnesium chloride and also dilutes the acid at the point of condensation. thus spreading it over a large surface of the metal.

Acid Corrosion in Heat Exchanger

Another evidence of acid corrosion was noted when a tube in a tubular heat exchanger, in which the hot residual oil flowed around the tubes and crude oil through them, suddenly started to leak. The heat exchanger was arranged with baffle plates so that the crude oil made four passes through the tubes in going from the bottom to the exit at the top. It was first thought that the tube had given way as a result of the abrasion of the earthy matter which is always carried along with the crude, but when the tube was removed the hole was found to be on the top side. If the abrasive matter had caused the hole, it would probably have been on the bottom, since such matter is heavier than oil, especially when the oil is warm and the viscosity thus decreased.

Careful examination of the removed tube showed the hole had been made from the inside, and the fact that it was on top supported the idea that it was another case of hydrochloric acid corrosion. Comparison with the other examples of this sort of corrosion helped to confirm this conclusion.

It was rather surprising to learn, however, that hydrochloric acid corrosion had taken place to such an extent at that particular point, since the temperature of the crude oil there was seldom above 110 deg. C. (230 deg. F.). Investigation, however, showed it was decidedly feasible, since oil-well casing has been known to be badly corroded by such action and Rogers[3] calls special attention to this point, showing that it is possible for this corrosion to take place at such temperatures. To be sure, the action at that temperature is slight, but is not to be ignored. The heat exchanger referred to had been in service for about 1½ years before the tube gave way, thus furnishing concrete evidence that the action is slow but positive.

Remedial Measures

Experience here has shown that ammonia introduced into the vapor fractionating system of pipe stills is the best combative agent thus far found for reducing the corrosive effect of the hydrochloric acid. In addition it no doubt neutralizes organic acids which might aid in the corrosion. Ammonia will not prevent such effects as noted in the heat exchanger, however, since it is introduced beyond that point in the vapor system. Also the use of ammonia on a bench of stills would be rather difficult, due to the necessity for introduction into the vapor system of each still. Thus, on the whole, the most practical solution would be to remove the salt water from the crude oil as it come from the well, or at least before it is put into the pipe line. Various methods of dehydration of crude oil have been proposed and some are in use, but none has yet removed the brine so thoroughly that this sort of corrosion would be entirely prevented.

The authors desire to acknowledge the assistance of P. E. Foster and R. C. Roberts, who are directly in charge of the stills where these observations have been made.

The A.P.I. Scale for Reporting Gravity of Liquid Petroleum Products

In reporting the gravity of liquid petroleum products, the United States Petroleum Association in 1864 adopted a scale, or rather a set of instruments graduated in accordance with a scale, on which the readings were expressed in "degrees Baumé." Since that time this scale has been in general use, without change, throughout the petroleum industry. Later investigation following the adoption of this scale showed it to be represented by the conversion modulus 141.5.

In industries other than the petroleum industry, however, an American standard Baumé scale based on a modulus of 140 has found universal use for reporting the gravity of liquids lighter than water.

The confusion arising from the use of the two scales —namely, 140 and 141.5—the readings on both of which were designated in "degrees Baumé," was brought to the attention of the American Petroleum Institute by representatives of the petroleum industry and, at the same time, the necessity was urged of having one or the other of the two scales formally adopted as a single standard for the industry. The technical advisory committee of the American Petroleum Institute then recommended the adoption of the gravity standard based on the modulus of 141.5, which is most generally in use by the petroleum industry, and on Jan. 23, 1922, the Institute transmitted broadcast to the oil industry a questionnaire which was, in substance, as follows: (1) Do you approve of the modulus 141.5 as applied to the oil industry? (2) Do you approve that the scale be known as the "American Petroleum Institute Scale"? To this inquiry the replies were almost unanimously in the affirmative.

After careful consideration of the question it has now been agreed by the American Petroleum Institute, the Bureau of Mines and the Bureau of Standards that the scale based on the modulus 141.5 be approved and recommended for exclusive use in the petroleum oil industry, and that this scale be designated the "American Petroleum Institute Scale." This action is believed to be in the interest of uniformity of practice within the petroleum industry.

When reporting gravities of liquid petroleum products it is to be understood, therefore, that the hydrometer scale based on modulus 141.5 is standard, and the expression "degrees A.P.I." should be used in order to avoid confusion with the scale based on modulus 140. In reporting the gravity of liquids lighter than water, the United States Bureau of Standards has requested that the expression "degrees Baumé" apply only to the scale based on modulus 140. In cases of doubt or when disputes may arise it is recommended that the gravity reported in "degrees A.P.I." be followed by the statement of the "true specific gravity" in parentheses.

Dip-Brazing With 80:20 Brass and the Heat-Treatment of Brazed Joints

Determination of Satisfactory Methods for Dip-Brazing—Tests on the Strengths of Joints and the Effect of Heat-Treatment—Metallography of Brazed Joints—An Explanation of the Great Strength of the Bond Between Brass and Steel

BY E. V. SCHAAL
Metallurgist, U. S. Air Service, Engineering Division, McCook Field, Dayton, Ohio

BRAZING is by no means a new art, but there are many phases of the subject that have not been covered by the available literature.[1] Especially does this apply to dip-brazing in a high melting point brass and subsequent heat-treatment of the parts. Airplane construction has opened a new field for this art, and in order to use alloy steels at their fullest advantage, heat-treatment of fittings after brazing has become desirable if not necessary.

The experimental work with which this paper is concerned was carried out in the metallurgical laboratory of the Engineering Division of the U. S. Air Service at McCook Field with a view toward establishing a method of satisfactorily dip-brazing and heat-treating alloy steel fittings as well as obtaining data on the strength of brazed joints both in the heat-treated and non-heat-treated conditions.

Brazing Bath

The brazing was done in an ordinary plumbago crucible heated in a melting furnace fired with gas. The brass was made by first melting the copper under a layer of borax or boric acid and finally adding preheated zinc in small pieces. Using a flux over the molten metal held down the zinc loss due to volatilization. The proportion of 80 per cent copper and 20 per cent zinc was used on all the brazed joints reported herein (except a few specimens when a nickel brass was used), varying less than 1 per cent, as shown by chemical analyses made after the brass had been used.

Surface Appearance Caused by Various Fluxes

It was found that a clean specimen could not be obtained by the ordinary method of dipping in brass covered with a layer of borax, due to the rapid volatilization of the zinc and oxidation of both zinc and copper on the surface of the specimen after it was removed. This difficulty is not encountered in brazing with alloys of lower melting point. The high brazing temperature required for 80:20 brass apparently renders the flux very fluid, and permits it to run off the specimen almost the instant it is withdrawn, thus exposing the surface of the hot metal to the atmosphere. In an effort to overcome this difficulty, boric acid and potassium metaborate were both tried as fluxes. A slight improvement was found with potassium metaborate, but it was discovered that a thick layer of boric acid (1 in. or more) nearly obviated the difficulty. However, there were still discolored spots on the specimens.

It was also discovered that if the specimen were immediately transferred into a bath of molten borax or boric acid at about 1,500 deg. F., and held there from 30 seconds to 1 minute, the surface luster was preserved after it had been withdrawn and cooled to room temperature. When a cooling bath of flux is used, its temperature should be 200 to 300 deg. F. below that of the brass. Borax can be kept at a lower temperature, but boric acid becomes too viscous below 1,600 deg. F. and clings in a mass to the specimens when they are withdrawn. Boric acid is otherwise much more desirable, because it can be washed off in hot water, while borax must be cracked off either by quenching, by pounding with a hammer or by a sand blast.

Joints Made by Different Fluxes

As it was desired to determine the flux that would produce the strongest joint with the 80:20 brass, five butt specimens of S.A.E. 1020 steel were brazed with each of the following fluxes: Potassium metaborate, boric acid, borax. Borax was used as a cooling flux.

All the specimens were preheated to a dull red heat before dipping in order to speed up the process and prevent cooling the brass unduly after inserting each specimen. They were allowed to remain in the brass at 1,825 to 1,850 deg. F. for 2 minutes, during which time they were moved up and down. Thereupon the brazed pieces were transferred to a cooling flux of borax at 1,500 to 1,550 deg. F., where they remained 1 minute, then removed and cooled in air. Results are shown in Table I.

Borax appears to be the most desirable flux from the standpoint of the strength of the joint. However, the latter part of the work reported herein was done with a layer of boric acid 1 or 2 in. thick as a flux, and the cooling flux was dispensed with. As noted above, this was done to simplify the process, and it was found that the specimens came out as clean by this method as

[1] "The Metallography and Heat-Treatment of Metals Used in Aëroplane Construction," F. Grotts, CHEM. & MET. ENG., Aug. 1 to Oct. 1, 1918. "Brazing, Welding and Soldering in Aëroplane Construction," Boulton, *Aerial Age*, Oct. 6, 1919. "The Heat-Treating of Brazed Fittings for Aircraft," Archibald Black, *Journal*, S.A.E., March, 1920.

when a cooling flux was used and borax used on the brass. It is believed, however, that borax is more active as a flux than boric acid, and therefore it removes oxide from the joint much quicker, insuring a better joint where there happens to be an excessive amount of scale caused from preheating in an oxidizing atmosphere.

As a means of preventing oxidation of the joints of airplane fittings during preheating, a paste was made by mixing equal parts of borax and boric acid in a little water. The parts to be brazed were dipped into this mixture before heating, and it was found that preheating to a dull red heat produced no scale, as the surfaces and joints were protected by a film of the molten flux. It may be suggested also that the use of a flux while preheating would tend to increase the reliability of the brazing job, since it not only prevents scaling of the joints during preheating but also insures that the joint is well supplied with flux before the brass comes into contact with it.

Preparation of Butt Specimens

Standard tensile test specimens were cut in the middle and the ends faced off square in a lathe. These specimens were left approximately 0.08 in. oversize and no threads were cut on the ends. In order to hold the two parts of each butt specimen in place while brazing, two steel strips, or stays, were welded to opposite sides by means of an acetylene torch, care being taken to align the two parts as nearly as possible. During welding the heat was confined as much as possible to the ends, and there it was very much localized. The middle part, where the braze was to be made, never became hotter than 1,000 or 1,100 deg. F. during the welding of the stays, and excessive oxidation of the surfaces to be brazed was therefore avoided.

Final machining consisted of cutting off the stays, turning the specimen true in a lathe and cutting threads on both ends. This left them clean and true with no brass on them except at the joint.

Strength of Butt Joints

After it was determined to use borax as a flux over the brass, two series of tensile tests on butt joints were made, as shown in Tables II and III. In both cases the brazing temperature was kept within 25 deg. of 1,850 deg. F., the specimens were immersed 2 minutes, then transferred for 1 minute to a borax bath at 1,525 — 25 deg. F. Carbon steel samples were machined and tested, giving an average strength at the joint of 32,680 lb. per sq.in. with three bad samples below this figure. S.A.E. 2335 nickel steel specimens in Table II were quenched in oil from 1,500 deg. F., and drawn at 1,000 deg. F. before testing. Under these circumstances the average strength at the joint was 62,290 lb. per sq.in. and of the steel 149,000 lb. per sq.in. Four samples were so imperfectly joined as to give strengths below this average.

The effect of heat-treatment upon brazed joints is yet uncertain. After obtaining the increased strength from heat-treating nickel steel butt joints as compared with the non-heat-treated carbon steel joints, it was thought that perhaps heat-treatment was a means of increasing the strength of the bond between the two pieces of steel, but later results do not uphold that idea. It is more likely that the brass in tension in the butt joints was supported more by the hard nickel steel than by the soft carbon steel so that the process of necking (which originates in the brass itself) was retarded, causing a higher breaking load. Such a phenomenon as that just described could not take place in a shear test and there was later found no evidence of an increase in shearing strength due to heat-treatment or to the use of nickel steel.

Strength of the Brass

After completing the brazing of the butt joints, three tensile specimens were cast from the brass in sand molds. These specimens were used for tensile tests, shear tests and chemical analysis, and gave extremely consistent results. The castings for the test specimens were poured at the brazing temperature (1,825 to 1,850 deg. F.). Results follow:

Chemical analysis: Cu 79.12, Zn 19.54, Fe 1.34, Sn trace, Pb trace. Ultimate strength in tension, 44,803 lb. per sq.in. Elongation in 2 in., 28.7 per cent. Ultimate strength in shear, 33,530 lb. per sq.in.

Tensile Tests on Lap Joints

A series of carefully made lap joints were tested in tension, but the results were so variable that this method was abandoned as fundamentally incorrect. Therefore a shear specimen was designed and used on all later work on brazing. Butt specimens, while giving fairly uniform results, were extremely difficult to manipulate and expensive and so were discarded in later tests. Shear specimens were made of ¼-in. stock, lapped about ⅝ in. and riveted at each end, making a piece approximately 1½ in. in length with a distance between the rivets slightly exceeding 1 in. One of these specimens is shown in the photograph, Fig. 1, taken after the specimen had been brazed. A hole was drilled in one corner through which a wire could be inserted for dipping. After the brazing had been completed, both ends of the specimen were cut off, thus removing the rivets, and the area of the lap was reduced to exactly ½ sq.in.

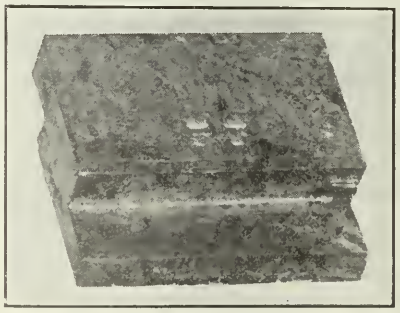

FIG. 1—SHEAR SPECIMEN AFTER BRAZING AND BEFORE MACHINING

Nickel Brass for Brazing

After adopting the shear specimen for brazing tests, the investigation was divided into four steps, as follows:

1. Determination of the merits of a nickel brass.
2. Determination of the proper brazing temperature.
3. Determination of proper clearance between parts.
4. Determination of the effect of heat-treatment.

The first inquiry was conducted by brazing ten specimens of low-carbon steel with 80:20 brass and ten with a nickel brass made with about 6 per cent of nickel substituted for that amount of copper. A clearance of about 0.0025 in. was used on these specimens, a thin copper shim being placed at each end between the two parts just before riveting. A brazing temperature of 1,850 to 1,860 deg. F. was maintained. Borax was used as a flux and boric acid used as a cooling bath. Results follow:

Ultimate strength in shear of the 80:20 brass joints: 36,840, 36,800, 37,680, 34,800, 31,320, 35,840, 36,300. Average: 35,650 lb. per sq.in. Three specimens were not completely brazed over the joint, giving values of 29,890, 25,480 and 28,760. If these are computed with the others, the average strength is lowered to 33,370 lb. per sq.in., approximately the shearing strength of the brass itself.

None of the specimens joined with the nickel brass was completely brazed. Ultimate strength in shear: 25,340, 26,480, 21,540, 25,060, 21,200, 22,060, 24,420, 27,140, 26,860, 24,440. Average: 24,450 lb. per sq.in.

Specimens of the nickel brass were cast and tested with the following results:

Chemical analysis: Cu 73.3, Ni 5.4, Fe 0.85, Zn 20.4. Tensile strength, lb. per sq.in. (average of three ½-in. specimens), 34,666. Elongation in 2 in., per cent, 34. Shear on one ½-in. specimen, lb. per sq.in., 20,450.

Therefore, the use of nickel in the brazing brass with a view toward improving the flowing qualities proved to be useless, as it not only weakened the brass but gave a less uniformly filled joint.

Correct Temperature for Brazing

Before the work was started on the shear specimens, no systematic determination of the proper brazing temperature was made, but the general appearance and behavior of the brass during the brazing of the butt and lap joints had led to the conclusion that 1,850 deg. F. was the proper temperature to use with 80:20 brass. This conclusion was found to be correct after the second series of the shear specimens, shown in Table IV, had been tested.[2] If the imperfect specimens be disregarded, it will be observed that there is a variation of approximately 4,000 lb. per sq.in. in the averages from each group and that the greatest strength is obtained with the lowest brazing temperature. While these results indicate that the low temperature of 1,830 deg. is best, there is danger in maintaining the brass at that temperature, because it is liable to freeze around the specimens when they are inserted. Raising the temperature to 1,850 deg. prevents this danger and does not lower the strength of the joint any appreciable amount. This latter temperature has been used for brazing airplane fittings, and has proved very satisfactory.

* Flaw in brazing.

[2]All specimens were low-carbon steel, brazed with 80:20 brass under borax, and cooled in boric acid.

Effect of Clearance Between Parts

After the second series was completed the brazing temperature of 1,850 deg. F. was adopted as the proper one and the third group of soft steel specimens was made up, varying the clearance from zero to 0.0075 in. There were twenty specimens in this group with four different clearances. Table V shows the results.

TABLE V—SHEAR TESTS TO DETERMINE THE EFFECT OF CLEARANCE

3	28,810	.....	85
3	28,920	.....	90
3	30,320	29,030	90

It is evident that a very small clearance is best. Of course it is possible on a closely fitted joint, put together with a great deal of pressure, to prevent penetration of the brass, but in general a thin crack fills better than a thick one. An explanation of this probably lies in the fact that the brass enters the crack by capillary attraction, and the smaller the capillary the greater the attraction becomes.

Heat-Treatment of Shear Joints

Twenty-one carbon steel specimens and the same number of S.A.E. 2330 nickel steel specimens were prepared. Following the best results obtained in the previous work, no clearance was used, and the brazing temperature was maintained at 1,850 deg. F. as nearly as possible. Borax flux and a boric acid cooling bath were used. Heat-treatment consisted of a quench in oil from 1,625 deg. F. for the carbon steel and 1,500 deg. F. for the nickel steel, followed by a draw to 1,000 deg. F. in saltpeter for all specimens. Half of the specimens made from each steel were heat-treated and the remainder were tested without heat-treatment. The machine work was all completed on these specimens before heat-treatment. Results are shown in Table VI.

The results from the heat-treated specimens were so poor that it was decided to braze some 6-in. specimens that had been spot-welded with the acetylene torch to hold them together. They were made of carbon steel, six of ¼-in. strips and six of ⅛-in. strips. These were heat-treated (quenched from 1,600 deg. F. and drawn to 1,000 deg. F.) after brazing and then tested with a chisel and hammer to determine whether the

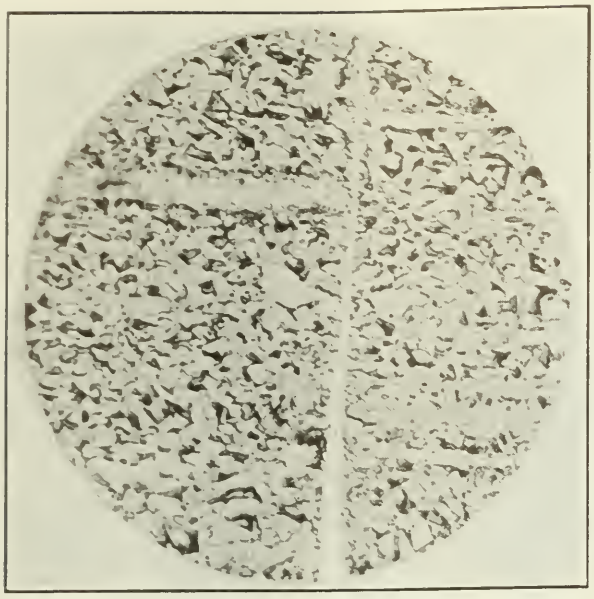

FIG. 2—BUTT JOINT IN LOW-CARBON STEEL, WITH BRASS ENTERING A MICROSCOPIC CRACK. × 100

joint had been injured by the treatment. They were found to be in good condition and three shear specimens were cut from two of the specimens made of ¼-in. stock. Ultimate strength of these specimens was 27,520, 31,820 and 23,660 lb. per sq.in. respectively. The latter showed incomplete brazing, but the two others held until the steel bent—testing was done with one end of shear knife unsupported. Evidently these larger, more rigid specimens were not so badly damaged by the heat-treatment.

TABLE VI—SHEAR TESTS TO DETERMINE EFFECT OF HEAT-TREATMENT

TABLE VII—SHEAR TESTS ON BRAZED CARBON AND NICKEL-STEEL

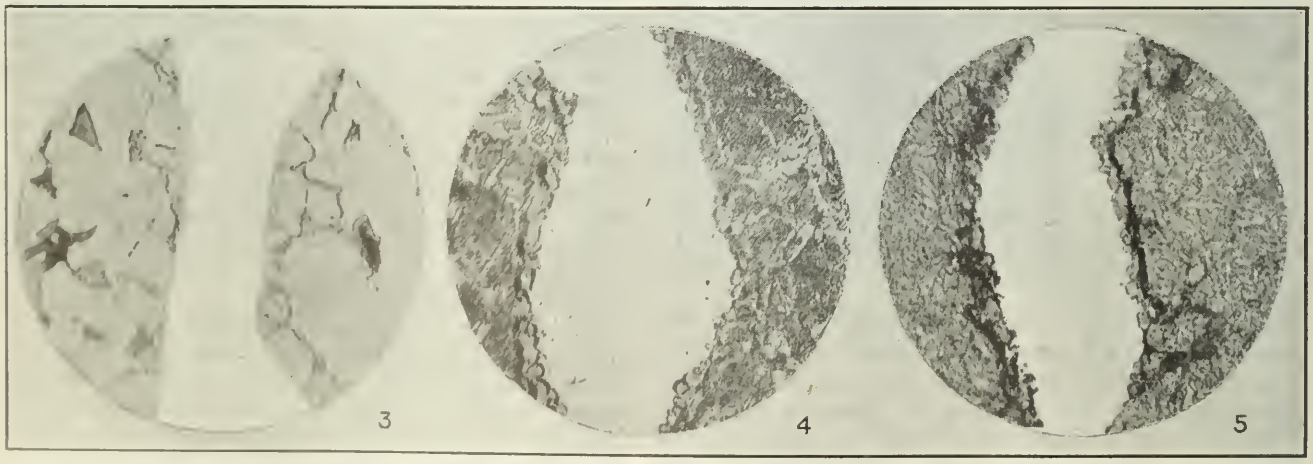
Low-Carbon Steel		Nickel-Steel	
Ultimate Strength Lb./Sq.In.	Character Of Fracture	Ultimate Strength Lb./Sq.In.	Character Of Fracture
495	Oxide	5,630	Oxide—¼ brazed
23,010	¼ brazed	30,280	¼ brazed
18,240	¾ brazed	36,550	$\frac{9}{10}$ brazed
19,900	¼ brazed	1,370	$\frac{1}{10}$ brazed
660	Oxide	22,420	¾ brazed
		25,000	¾ brazed

Thereupon another set of six each of nickel-steel and carbon-steel shear specimens was made, brazed and heat-treated. The final machining of this set of specimens was left until after the heat-treatment in order that the joints might be supported by the rivets during that operation. No shims were used in the joint. Brazing was done at 1,850 deg. F. under a deep flux of boric acid, and no cooling bath was used. Carbon steel was quenched from 1,600 deg. F., nickel steel from 1,500 deg. F. in oil, and all drawn back to 1,000 deg. F. after brazing but before machining. The results of this test are shown in Table VII.

Failure at low strength of nearly all of the heat-treated shear specimens cannot be satisfactorily accounted for, inasmuch as specimens of the same dimensions cut from the 6-in. spot-welded specimens gave good results. That the heat-treatment of first specimens weakened the bond cannot be doubted; since these were taken at random from the whole series, all brazed at the same time and under the same conditions, producing unheat-treated specimens which were uniformly good. Even heat-treating these last shear specimens with the rivets in both ends of each seemed to have somewhat of the same effect as it did on those that were machined before heat-treatment. But on none of the other types of specimens was there any detrimental effect from heat-treatment. It must be concluded, therefore, that the particular type of specimen that was used for shear tests was especially susceptible to deterioration. Just how extensive this may prove to be in airplane fittings cannot at present be stated, but no such trouble has thus far been experienced on brazed and heat-treated fittings made of nickel steel.

Metallography

Figs. 2 to 9, inclusive, are microphotographs taken of several representative brazed joints, all etched with 5 per cent HNO_3 in alcohol. Fig. 2 shows how the brass flows into a microscopic crack and it also demonstrates

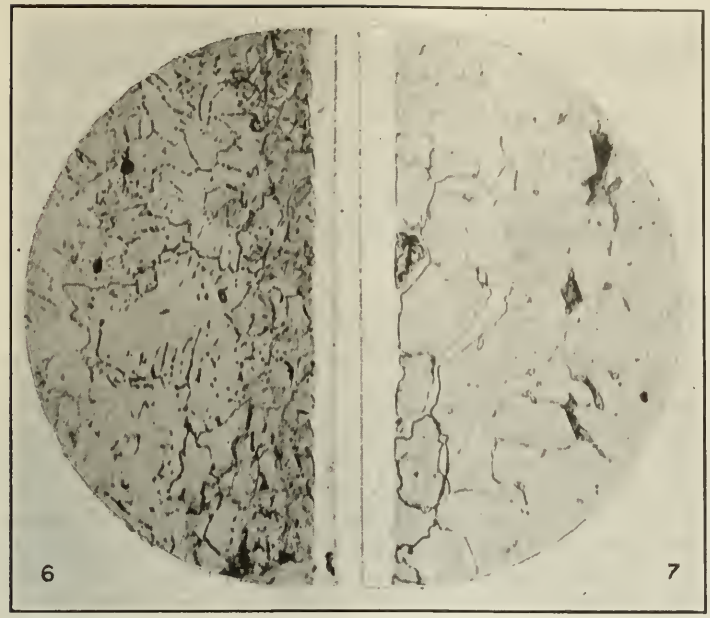


FIGS. 3 TO 5—SPECIAL INTERGRANULAR CONSTITUENT. × 350

Fig. 3—Low-carbon steel, no heat-treatment.

Fig. 4—Nickel-steel, no heat-treatment.

Fig. 5—Nickel-steel after heat-treatment.



FIGS. 6 AND 7—LAP JOINT IN CARBON STEEL, RESPECTIVELY BEFORE AND AFTER HEAT-TREATMENT. × 500

that this low-carbon steel does not develop large grains when brazed at 1,850 deg. F. Fig. 3 shows the same joint at a higher magnification, and reveals a constituent at the boundaries of the ferrite grains which has formed out of the brass in association with the iron. This constituent does not reveal itself to the eye on the unetched surface of the specimen, but after a light etch of nitric acid in alcohol it is clearly differentiated from the brass and the normal constituents of the steel.

Fig. 4 shows a similar constituent in a nickel-steel specimen. Here it presents a brownish tint when etched with HNO_3 instead of the gray color of Fig. 3, suggesting that the nickel in solid solution with the ferrite has also entered the substance which encroached upon the ferrite grain boundaries. In Fig. 5, heat-treated after brazing, this constituent shows a darker shade of brown, but with indistinct boundaries as in Fig. 4. All the remaining microphotographs show this constituent either in the light gray color or in the fuzzy brown. Note Fig. 7, in which it shows light colored with distinct boundaries, and Fig. 6, in which it is brown and fuzzy after heat-treatment. Note also that in all carbon steels, heat-treatment is necessary to cause diffusion of this constituent, while in the nickel steel the diffusion takes place before heat-treatment, and that the diffusion is accompanied by a change in color from gray to brown. As mentioned above, a very light etch is necessary to bring out any difference in color between the special constituent and the steel. There is apparently no tendency for the steel to diffuse into the brass, which is reasonable, since the steel remains solid, while the brass is molten.

The fact that all well-brazed joints which fail while being tested or otherwise do so by severing the brass and not by separating the brass from the steel is readily explained by the interlocking of the two by means of an intermediate constituent, which is undoubtedly stronger than the brass.

Summary and Conclusions

Preheating to a dull red just before brazing is found desirable, but a higher temperature or continued heating should be avoided on account of oxidation of the surfaces to be brazed. It is found advisable to coat the parts to be brazed with a paste made of borax and boric acid to prevent oxidation during preheating.

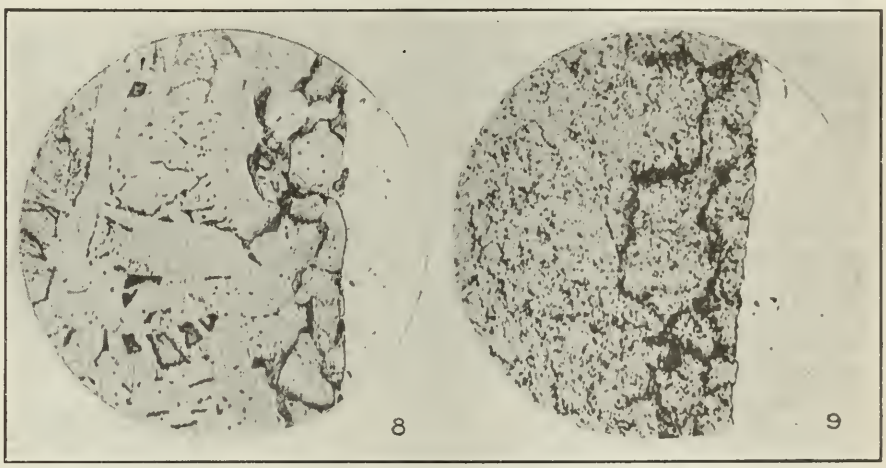
Borax gives the best joints when brazing with 80:20 brass, but should be used in connection with a cooling flux, preferably boric acid, in order to prevent surface oxidation of the specimen.

The proper brazing temperature is found to be 1,850 deg. F.

The best joints are obtained when the surfaces to be brazed are fastened close to each other by any suitable means without the use of shims or spacers.

The strength in pure tension of joints made with carbon steel, untreated, is approximately equal to the strength of the brass in tension. That of the nickel steel joints, heat-treated, is nearly twice the strength of the brass. The strength of joints in pure shear is approximately equal to the shearing strength of the brass. The shearing strength is also approximately equal to the tensile strength of the brass.

Nickel steel joints tested in shear give approximately the same results as carbon steel joints tested in shear.



FIGS. 8 AND 9—LAP JOINT IN NICKEL STEEL, RESPECTIVELY BEFORE AND AFTER HEAT-TREATMENT. × 350

Heat-treatment of brazed parts is shown to deteriorate certain types of joints brazed with 80:20 brass.

Metallographic study of brazed joints shows that low-carbon steel is not overheated by dip-brazing, and reveals an intermediate constituent between the brass and the steel which serves to hold the brass and steel together in the joint.

Aluminum Production in 1921

The value of the aluminum produced in the United States in 1921 was $10,906,000, as compared with $41,375,000 in 1920. This great decrease was due not only to a decrease in the price of the metal but to the large curtailment of its use in the automotive industries. Imported aluminum could be bought throughout the year at 2 to 3 cents below domestic prices.

The Lead Plate Test as Applied to Commercial Detonators

A Description of the Test and Series of Experiments Demonstrating Its Value in Grading Commercial Detonators According to Well-Defined Standards and Discussion of Various Factors Influencing the Efficiency of Commercial Detonators

By Bennett Grotta
Detonator Section, Reynolds Experimental Laboratory, Atlas Powder Co.

In THE entire realm of commercial explosives, no more important rôle can be found than that played by the seemingly insignificant detonator. The best explosive on the market will not function properly, if at all, with an improperly designed or defective detonator, while, on the other hand, comparatively low-grade explosives, ordinarily incapable of application, may be rendered most useful by employing specially constructed detonators. In short, the detonator is the brain and nerve system at whose command the brawn of high explosives is converted into useful work. It is doubtful if Nobel's invention of dynamite in 1864 would have been a memorable contribution to the development of commercial explosives had he not also, 3 years later, suggested the use of fulminating mercury detonators. Since that time numerous other explosive compounds have been proposed for a similar purpose, but as yet the advisability of wholly dispensing with fulminate of mercury has not been fully demonstrated.

That particular property of fulminate of mercury which renders it so well suited for initiating high explosives is difficult to describe; to devise an absolute test or means of measuring this property in fulminate of mercury or other compounds is still more difficult. Yet the need for such a test which is capable of application and interpretation, by either the maker or user of explosives, is urgent. The user could avoid many costly and dangerous misfires if he would only ascertain whether his detonators were efficient and in good condition. Manufacturers of commercial explosives would be spared many unjustified complaints if the use of inefficient and defective detonators could be eliminated.

Numerous tests have been proposed during the history of commercial detonators, but of these there is one which has survived the trial of more than a quarter of a century of extensive application and which is today the most widely known and universally used of all. It is known as the lead plate test and consists of firing a detonator while supported in a vertical position, its base resting on the center of a lead plate about 1½ in. square by $\frac{3}{8}$ in. thick. The purpose of this article is to describe the application of the lead plate test, the interpretation of results in terms of ability to initiate commercial explosives, and also to describe some of the factors which affect the efficiency of detonators as revealed by this test.

Device Used for Test

A very satisfactory lead plate testing apparatus is shown in Fig. 1. As many as seventy tests per hour have been made with this machine. Another modification is shown in Fig. 2. It should be observed that the essential feature of both types is a hollow support for the lead plate and a device for supporting the detonator, crimped onto a short section of fuse in a vertical position and in the center of the lead plate. The tester in Fig. 1 may be adjusted for various sizes of detonators by changing the position of the cotter pins in the upright standards. The tester in Fig. 2 may be adjusted by merely sliding the horizontal bar up or down on the two vertical standards. A complete tester could be made by any blacksmith in an hour's time and would be ready for immediate use in any well-barricaded location.

Lead plates may be cut from 12-lb. sheet lead, but it is more convenient and economical to buy the plates ready cut.[1] Tape fuse may be purchased in 2-in. lengths, which are convenient when a large number of tests are to be made.[2] Ordinary safety fuse, however, is entirely satisfactory. The barricade should be either of wood at least 2 in. in thickness or of sheet iron at least $\frac{1}{8}$ in. in thickness. Lighter lumber may be used if the barricade is steel lined. Obviously, the same tester may be used for testing electric detonators, the only difference being that the lead wires, instead of the fuse, are threaded through the guide, and the detonator is fired from a safe distance by means of an electric battery.

Interpretation of Plate Tests

The appearance of the lead plate after the detonator is fired furnishes a pictorial representation of the explosive action of the detonator charge. In the center

[1]Ready cut lead plates may be obtained from the United Lead Co., Philadelphia.

[2]Two-inch lengths of fuse may be obtained from the Ensign Bickford Co.

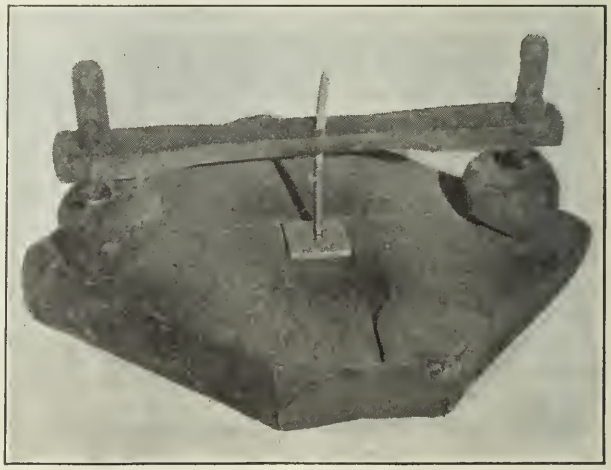


FIG. 1—DEVICE USED FOR LEAD PLATE TEST, SHOWING PLATE AND DETONATOR IN PLACE

of the plate at the point of contact with the base of the detonator there occurs a depression which is dependent for depth both upon the size and quality of the detonator. Radiating from this central depression or perforation, as the case may be, are numerous striations of fine dotted lines. These striations constitute the real index to the quality of the detonator and the explosive effect of its composition. Each dotted line is the result

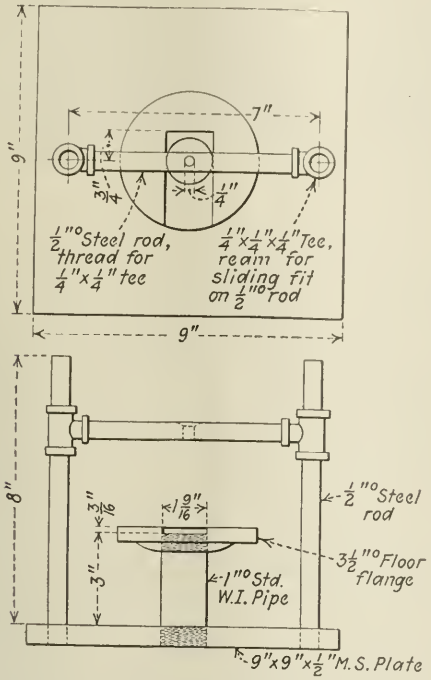

FIG. 2—TESTING DEVICE MADE FROM STANDARD PIPE FITTINGS

of a glancing blow inflicted by a single particle of the detonator shell.

The detonation of a good quality fulminate of mercury charge bursts the shell wall into innumerable concentric rings, each of which is, in turn, shattered into numerous small fragments. As the quality of a fulminate of mercury detonator is lowered, the size of the shell fragments becomes larger, due to a less brusque

TABLE I—TABULATED DESCRIPTION OF LEAD PLATES

Classification	Quality of Detonator	Indentation	Back Side of Plate	Radiations	Pittings	Remarks
A	Good	Deep, very often penetrating plate	Peeled	Fine Uniform	None	
B	Good	Deep, very often penetrating plate	Peeled	Practically uniform	Few Small	
C	Fair	Deep, very often penetrating plate	Peeled	Practically none	Large and deep	
D	Bad	Broad shallow	Not peeled	None	Large and deep	
E	Bad	Small, shallow	Not peeled	None	Large and deep	Often broad ribbon-like markings on face of plate.
F	Bad	Small, shallow and covered by remains of shell	Not peeled	None	Large and deep	Bottom and part of shell wall left on plate

action of the explosive charge, and radial striations on the lead plate tend to be replaced by large pittings or splotches at irregular intervals on the face of the lead plate, these pittings being caused by the larger fragments. If the detonator is of a very low quality, due to prolonged exposure to moisture, a defective grade of fulminate, a faulty mixture or any other cause, so that it may be practically worthless for detonating commercial powders, it will not shatter the shell into numerous small fragments, but will merely rupture the casing into a small number of broad strips. Consequently, with this detonator there are neither striations nor pittings, but instead, a few broad, ribbon-like impressions radiating from an almost imperceptible depression where the detonator was in contact with the lead plate.

Standards for Lead Plate Tests

As a matter of convenience, the various graduations of quality are classified according to six different standards, which are, in turn, designated by the first six letters of the alphabet, A being taken as 100 per cent and F as zero per cent quality. Fig. 3 shows a set of standards which represents the best judgment avail-

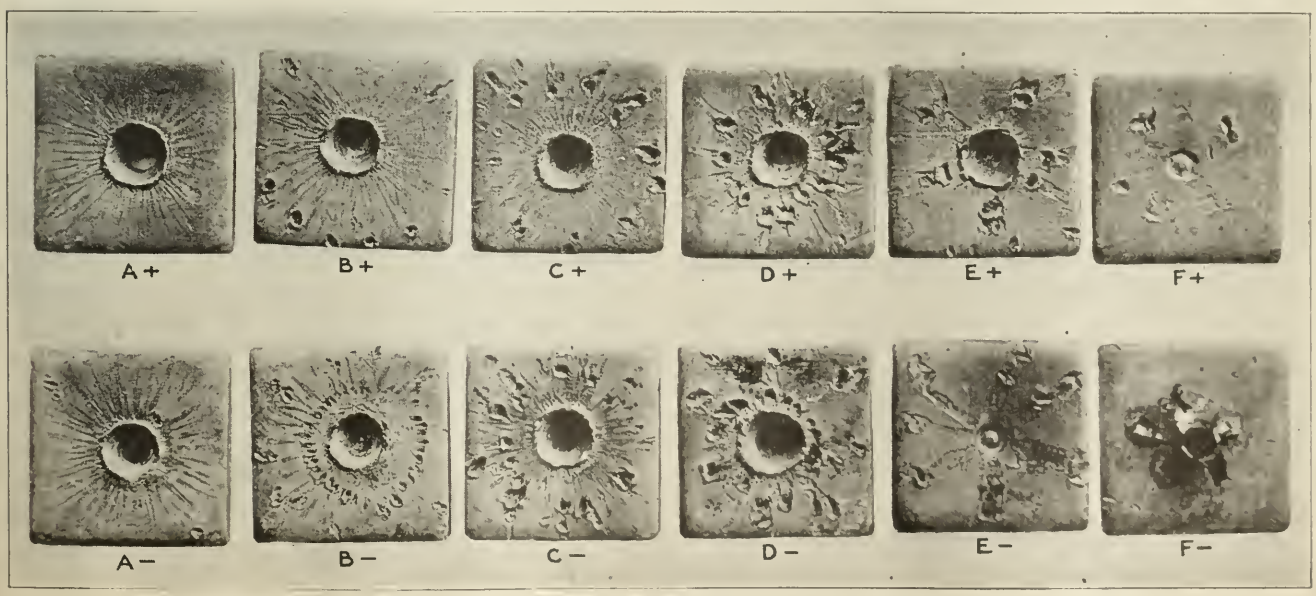

FIG. 3—SET OF STANDARD LEAD PLATES

able from several years of both intensive experience with fulminate detonators and also rather extensive experimental work with numerous other initiating compounds.

It will be observed that two plates are given for each designation, the upper plate being designated as "plus" (+), and the lower plate as "minus" (—). This is merely for the purpose of simplifying the application of the standards. Obviously, but few of the plates obtained in practice might exactly coincide in appearance with any one of a set of six hard and fast standards. Therefore, rather than a set of fixed averages, the upper and lower limits of each classification have been given. Equipped with a set of these standards and a tabulated set of descriptions as given in Table I, any one, no matter how unversed in the technique of explosives, should be able to determine the quality of the detonators he is using.

In recent years, plates made of aluminum instead of lead have become popular with salesmen, demonstrators and others who are in a position to appreciate the lightness of aluminum as compared with lead. A critical comparison of aluminum and lead plates for testing detonators has indicated that approximately similar results are obtained with both metals. Aluminum being a much harder metal, however, the impressions are not nearly as well defined as on lead plates, and it is therefore impossible to judge as closely the quality of the detonator. While lead is preferable, in general what applies to lead plates also holds true for aluminum plates.

Tests of Initiating Detonation of Explosives

It is axiomatic that the ultimate test for any detonator is its ability to initiate the detonation of commercial explosives. While, however, it is self-evident that the ideal detonator test is the detonation of dynamite, it is also obvious that such a test would involve a large number of trial shots which would make it too cumbersome and too costly for general application. In order that the results of the lead plate test might be capable of interpretation in terms of initiating value, it has been carefully calibrated by a direct comparison with several different series of dynamite detonating tests. The lead plate test has been described from time to time,[3] but as yet the actual significance of its results has not been demonstrated.

The initiating value of commercial No. 6 detonators, both as received and from lots representing two different stages of deterioration, as indicated by the lead plate test, was ascertained by using these detonators with several different lots of commercial explosives of various degrees of sensitiveness. The results of these tests are given in Table II.

The explosive used in series A consisted of a mixture of 92 parts of TNT and 8 parts of iron oxide (Fe_2O_3). This is an insensitive mixture that is frequently used by explosives manufacturers to establish various degrees of insensitiveness. By varying the iron oxide content, the susceptibility of the mixture to detonation may be closely controlled. The explosive used in series B was a straight nitroglycerine high-freezing dynamite giving an unusually high sensitiveness value. In series C, D and E, inclusive, commercial low-freezing explosives of various degrees of sensitiveness were used. Sensitiveness of the various explosives was determined as follows:

A standard cartridge of the explosive, 8 in. long by 1¼ in. in diameter is cut into two 4-in. sections. These two sections are then placed in a snugly-fitting paper cylinder, made of several layers of heavy wrapping paper, with the cut ends adjacent to each other. The detonator is fitted into one section and the maximum distance at which the two sections may be separated and still obtain propagation of the explosive wave from the first to the second section is determined by trial.

In test 1, No. 6 commercial detonators were used throughout. These detonators were supplied by a well-known manufacturer of detonators and were of the same type as the large majority of detonators now on the market. The explosive charge consisted of 1 g. (15.43 grains) of a mixture of 80 parts of fulminate of mercury and 20 parts of potassium chlorate. The detonators were of a regular run and were aged for several weeks in ordinary magazine storage before being used.

In test 2, No. 6 commercial detonators which showed partial deterioration due to wet storage were used. Ordinary detonators were placed in a humidor containing water, a small number were tested on lead plates every day and when B to C lead plates were obtained consistently the remaining caps were used for dynamite-detonating tests. In test 3 the deterioration was carried on until the detonators gave E to F lead plates consistently.

Typical lead plates of the above three lots of detonators are shown in Fig. 4. Interesting additional information on the disruptive effect on the shell of various detonators was obtained by firing the detonator in a bomb filled with ordinary salt. The salt was then dissolved in water, leaving behind the fragments of the detonator shell. From 92 to 98 per cent of the weight of the shell was accounted for in this way. The fragments from detonators used in dynamite-detonating tests 1 and 3 are shown in Figs. 5 and 6. It might be well to note that detonator shells from the same lot were used throughout in the manufacture of these detonators. This would preclude any assump-

Test 1 Test 2 Test 3

tion that the variations in fragmentations could be attributed to variations in hardness or in the degree of annealing of the shells—a point which is further considered in a later section of this article.

The significant result of the various dynamite-detonating tests may be summarized as follows:

1. Detonators, giving A to C lead plates inclusive, are suitable for detonating commercial explosives. Although it was not possible to distinguish between these classifications in detonating value, there is no doubt that detonators giving A plates are somewhat superior to C detonators. A possible explanation of the difficulty in distinguishing between the efficiency of these classifications is given later. At any rate, a preponderance of C plates in a lot of detonators indicates a general state of deterioration which may soon lead to a lower quality detonator, of questionable efficiency.

2. Detonators giving E to F lead plates may detonate extremely sensitive dynamites, but are useless for ordinary grades of commercial explosives. Furthermore it is doubtful if even the most sensitive explosives may be detonated to their maximum efficiency with a detonator of this classification.

3. Detonators of the intermediate classification of quality, giving D lead plates, should be classed with E and F lead plates with respect to initiating value.

FIG. 5—DETONATOR SHELL FRAGMENTS FROM NO. 6 COMMERCIAL DETONATOR USED IN DYNAMITE-DETONATING TEST 1

Several attempts were made to prepare D detonators, but it was found that when D quality was attained the lot would also contain a large number of E to F detonators and it was impossible to confine the deterioration to the D stage. Therefore, if for no other reason, D detonators may be condemned because of bad company.

Factors Influencing Detonation of Explosives

It is not within the scope of this article to discuss the theory of detonation, but in order to indicate an agreement between the lead plate test and the modern conception of the mechanics of detonation, reference will be made to a few generally accepted theories.

Commercial explosives are brought to a state of explosion by the generation of a sudden impulse by the detonator. In its ultimate analysis this impulse consists of an enormous local application of heat, but for practical purposes it may be observed that two distinct factors enter into the development and application of this impulse. These are quickness or brisance, and strength. In a well-designed detonator it is impossible to isolate these two factors, but both properties must be present in correctly balanced proportions, otherwise an inefficient detonator will be obtained.

Velocity of the chemical reactions involved is a function of quickness, while the total volume of the gaseous combustion products is a function of strength. Of these two properties quickness is by far the more important. In fact, it is conceivable that the element of strength is of importance only in that it sustains for an instant the concussion produced by the initiating impulse, and thereby tends to compensate for the dissipation of explosive energy up to and during that instant of application. Many compounds might be cited which excel fulminate of mercury in strength but which are useless for detonating purposes; also many compounds might be mentioned which excel in quickness but which are vastly inferior to fulminate in initiating value.

The lead plate test is essentially a measure of quickness. Strength may be estimated by either the modified Trauzel block[4] test or the sand test.[5] The reduced efficiency of detonators having impaired brisance or quickness is clearly demonstrated in the dynamite-detonating tests above in which E to F detonators were

[4]Colver, "High Explosives," p. 552 (1918).

[5]Storm and Cope, "The Sand Test," Bureau of Mines Technical Paper 125 (1916).

used. A reasonable explanation of the inability to distinguish between the efficiency of A and C detonators is that in an ordinary No. 6 detonator there is always a great excess of the strength element. Formerly, detonators containing but a fraction of a No. 6 charge were used extensively. The presence of this great excess of strength tends to mask any slight diminution in the element of quickness. Without doubt, a similar series of dynamite-detonating tests on No. 3 detonators (containing 0.54 g. of a fulminate-chlorate mixture) would reveal a lowered initiating efficiency with

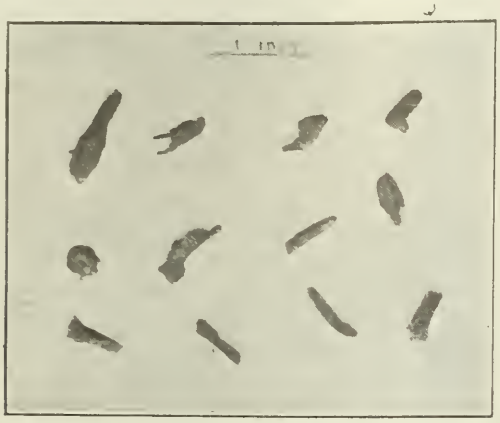

FIG. 6—DETONATOR SHELL FRAGMENTS FROM NO. 6 COMMERCIAL DETONATOR (WET) USED IN DYNAMITE-DETONATING TEST 3

each descending classification of lead paste. Since, however, No. 6 detonators comprise the bulk of the commercial article (in many countries it is illegal to market a detonator weaker than No. 6) all tests were confined to this grade.

Factors Affecting Efficiency of Detonators

An intensive study of the lead plate test would be incomplete without a consideration of the various factors which affect the efficiency of detonators as revealed by the lead plate test. The more important of these factors will be briefly reviewed in the following order:

1. Size of charge.
2. Moisture.
3. Potassium chlorate content.
4. Indentation of shells.
5. Hardness of detonator shells.

As was pointed out in a previous section of this article, the lead plate test is a measure of quickness rather than strength. The element of quickness in fulminate of mercury detonators does not vary greatly with the size of charge. Therefore the lead plate test does not indicate variations in weight of charges. This is demonstrated by the lead plates of No. 8 commercial detonators in Fig. 7. A No. 8 detonator contains just twice the charge of a No. 6 detonator.

It is true that, all other conditions being the same, the indentation in the center of the plate increases in size with the size of the charge. As the indentation is dependent on other factors also, and since the most pronounced variations are but slight, this is not a reliable index of weight of charges even in the hands of the explosives expert. It is gratifying to note, however, that under modern conditions of manufacture the tendency to produce undercharged detonators is rather remote. Reliable manufacturers build their charging machinery to deposit a standard charge and, when once constructed, it is practically impossible to operate these machines so as seriously to "short-weight" the detonator. Thus it is evident that this limitation of the lead plate test does not constitute an objection to its universal application.

Effect of Moisture

Moisture is universally admitted to be the greatest enemy of efficient detonators. This one factor is without doubt responsible for a very large majority of all detonator ills. An almost imperceptible moisture content is sufficient to impair seriously the ability to detonate commercial explosives. The E to F detonators used in the above dynamite tests were taken from a lot in which the explosive charge contained less than 1 per cent of moisture, while the moisture content of B and C detonators is scarcely weighable. Although the hygroscopicity of the potassium chlorate content is usually blamed for any tendency to take up moisture, the presence of a deliquescent salt is not a prerequisite for deterioration in wet storage. A fulminate charge absorbs sufficient moisture from condensation and capillary action to cause a rapid decline in efficiency under certain conditions. F detonators have been produced in two days storage in a humidor during certain summer seasons when there have been extreme changes between day and night temperature. Similar conditions prevail in many mines and most mining engineers are beginning to realize the importance of the "gospel of dry detonators." In addition to being urged to keep his detonator in a dry place, the blaster should be provided with facilities for making lead plate tests and encouraged to check up the efficiency of his detonators from time to time. Such a program would eventually yield big returns for the user, and also, indirectly, for the manufacturer of explosives.

Effect of Potassium Chlorate Content

Straight fulminate of mercury is seldom if ever used for detonator charges. This is due to the fact that, by itself, this compound is deficient in certain elements necessary to produce the maximum volume of combustion products, or, in other words, the maximum strength. Potassium chlorate is now used almost exclusively for the purpose of supplying this deficiency and it has been shown, both by chemical equations and actual experiments, that the most efficient mixture, from a standpoint of strength, is approximately 80 per cent fulminate of mercury and 20 per cent potassium

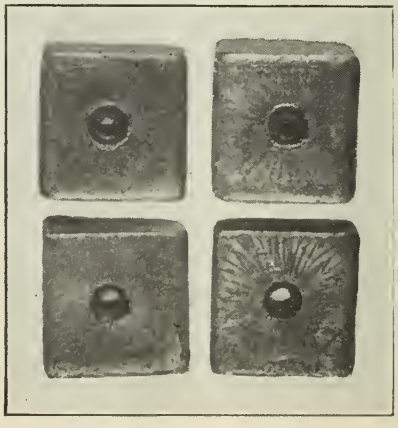

FIG. 7—LEAD PLATES FROM TESTS OF NO. 8 COMMERCIAL DETONATORS

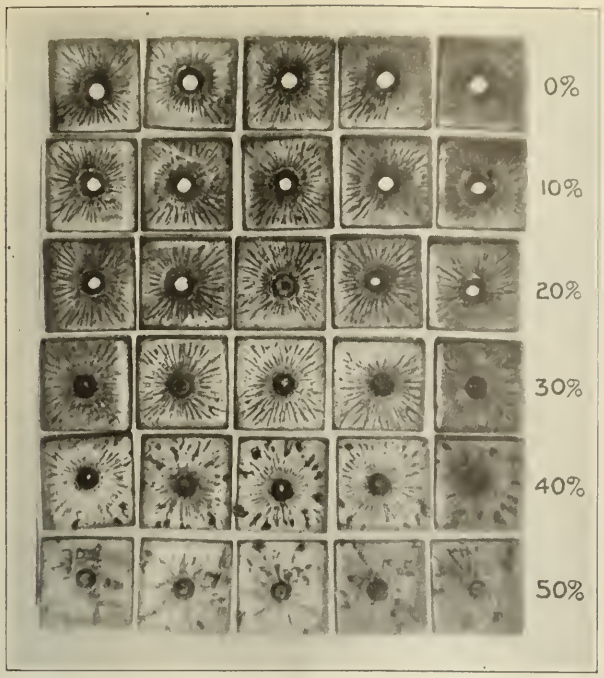

FIG. 8—EFFECT OF VARYING POTASSIUM CHLORATE CONENT (0 TO 50 PER CENT) IN NO. 6 DETONATORS

chlorate. The admixture of potassium chlorate in large quantities tends to detract from the element of quickness as indicated by the lead plate test, but without doubt the considerable increase in strength from the admixture of 20 per cent potassium chlorate more than compensates for any diminution of brisance. Fig. 8 shows the effect on detonators, as indicated by the lead plate test, of varying the chlorate content from 0 to 50 per cent.

Effect of Indentation of Shells

It is quite generally admitted by manufacturers of detonators that the efficiency may be modified by the shape of the detonator shell base. The shells of most commercial detonators bear a conelike indentation which tends to improve the quality of the lead plate both by rendering the radiations finer and more uniform and by causing a deeper indentation. Numerous explanations have been proposed for this improvement. Most of these explanations have been vague and fanciful and probably justly so, because it is very difficult to make accurate conjectures on such minute details in the mechanics of explosives.

In order to ascertain whether or not this indentation actually effected a more pronounced explosive action, or if the improvement were only superficial, several experiments were made which yielded rather interesting results. Two cartridges of 60 per cent gelatine dynamite 2x8 in. were placed on end on steel plates 5 in. square by 1 in. thick. Each steel plate was supported on a short section of wrought-iron pipe 2 in. in diameter, which, in turn, was placed on a rock foundation. A conelike indentation about $\frac{3}{4}$ in. in diameter by 3 in. deep was made in the lower end of one cartridge and the other cartridge was left intact. Both were detonated with No. 6 detonators.

The appearance of the steel plate after the shot indicated that the explosive effect had been greatly concentrated at the base of the "indented" stick of dynamite. In Fig. 9 *A* and *B* show the upper sides of the plates on which the indented and unindented sticks of dynamite, respectively, were detonated, while *C* and *D* show the reverse sides of the same plates in the same order.

In another series of tests made in connection with the effect of the detonator indentation, a number of commercial detonators were tested on lead plates, one half tested as received and the other half with the indentation filled with putty. The results (see Fig. 10) indicate that even though the indentation be filled with a plastic material, as is the case when the detonator is imbedded in a cartridge of dynamite, the advantage of this indentation is not abrogated.

But even after demonstrating that the indentation does effect a more concentrated explosive effect the task of presenting a suitable explanation remains. The diagram in Fig. 11 is intended to illustrate the lines of explosive force radiating from the interior surface of the indentation at the instant of detonation. These lines of force, or "explosive waves," always travel from the surface of the explosive by the shortest route—i.e., at right angles with respect to the surface of the explosive. Thus it is evident that in a perfect indentation—i.e., a 45 deg. cone, every line of force must collide with another line of force coming from the other side of the cone, the place of collision being the line of center. The result of these countless collisions, taking place simultaneously, is an added concussive effect or a greater concentration of explosive effect. A well-known example of a similar effect may be found in the ordinary Dautriche lead bar method of determining the velocity of detonation of powders.[9] An explosive wave is induced at the opposite ends of a small column of TNT. At the point where these waves collide a tremendous

[9]Dautriche, *Compt. rend.*, vol. 143, p. 641 (1906).

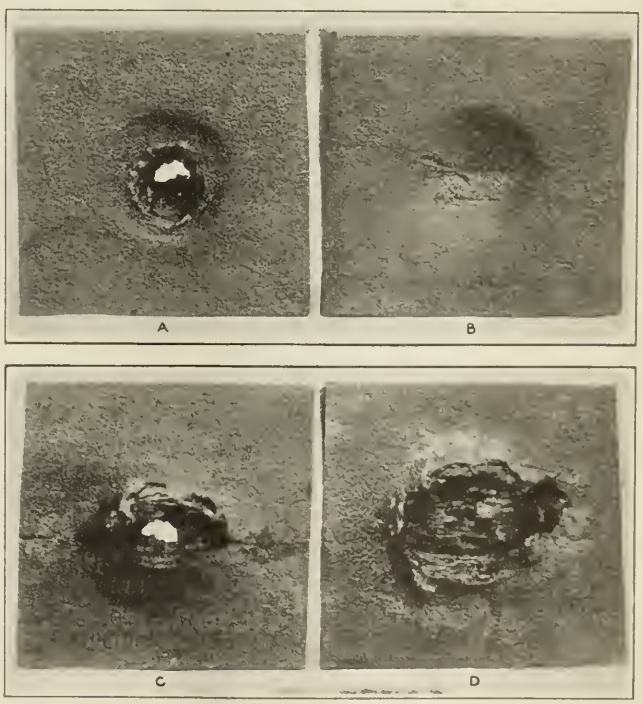

FIG. 9—COMPARATIVE EFFECT OF TWO CARTRIDGES OF 60 PER CENT GELATIN DYNAMITE ON STEEL PLATES. 1 x 5 x 5 IN.
A and B—Indented and unindented cartridges, respectively.
C and D—Reverse sides of plates, in same order.

concussion is produced, the effect of which may be discerned even on the reverse side of a lead bar ½ in. in thickness.

Effect of Hardiness of Shell

One of the very few objections which have been advanced against the lead plate test, and this is merely an imagined fault, is the belief that the quality of the test plate is greatly affected by the hardness or the softness of the detonator shell, thereby making possible the masking of a defective explosive composition by

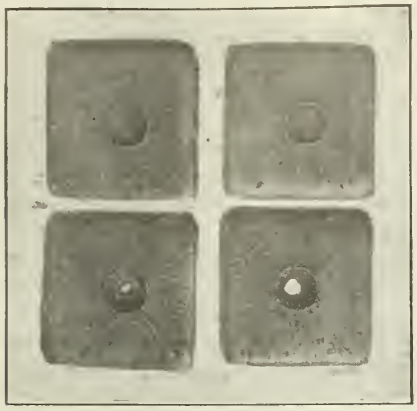

FIG. 10—LEAD PLATE TESTS ON NO. 6 DETONATORS WITH INDENTATION FILLED WITH PUTTY

using shells that are slightly harder or softer than normal. The fallacy of this assumption was demonstrated by the following experiment:

No. 6 commercial detonators were prepared using (*a*) gilding metal[1] shells that had not been annealed during any of the drawing operations and which represented an unusually high degree of hardness, giving a Shore scleroscope value of 58 to 60, and (*b*) shells of the same metal but which had been specially annealed to produce a soft shell, giving a scleroscope value of 36 to 38. Lead plates from both lots of detonators are shown in Fig. 12. These lead plates indicate that in a good quality detonator the resistance offered by the shell wall to the explosive force is so nearly negligible that the widest possible variations in shell hardness do not noticeably affect the disruptive action.

FIG. 11 — DIAGRAM ILLUSTRATING THE CONCENTRATED EXPLOSIVE EFFECT AT BASE OF INDENTED DETONATOR

In order to determine the range of variations in hardness between shells of commercial detonators a large number of scleroscope tests were made on a number of shells from detonators of the four leading manufacturers. The following four averages were obtained: 40, 41, 43, 44.

An attempt has not been made to cover the entire field of commercial detonators. Many points of theoretical interest might be included, but it has been the aim of this article to give only actual experimental data which would be helpful to explosives engineers and others who are interested in results rather than theories. Without doubt, a more intelligent and a more extensive application of a reliable detonator test will

[1]Gilding metal is the term applied to a copper alloy of approximately 90 per cent copper and 10 per cent zinc, which is used almost exclusively for detonator shell casings.

A—Annealed shells B—Unannealed shells

do much to promote efficiency and safety in the use of explosives.

"Know your detonator" should be the adopted slogan of every user of industrial explosives.

Acknowledgments

R. L. Hill and R. M. Cook have given much valuable aid in preparing the material for this article. Particularly the writer is indebted to Mr. Hill for helpful suggestions in conducting the various tests and in coordinating the results, and to Mr. Cook for the dynamite-detonating tests.

Liquid Soaps From Coconut Oil

By Michael Doniger

LIQUID SOAP may be described as an aqueous solution of soap, more particularly of a neutral potash soap. Its normal ingredients are water, glycerine and the potash soap of coconut oil. To be sure, liquid soap can be prepared from oil other than coconut, but it may be safely said that in most of these products consumed at the present time coconut oil is the fatty base, either singly or as the major component. This is not only because the properties of coconut oil fit it admirably for this purpose, but also because its cost is generally below that of any competing oil.

Ordinary solutions of soap in water are cloudy; properly made liquid soaps are clear, transparent and sparkling. These desirable properties depend to a large extent upon the presence of glycerine, alcohol or cane sugar in the finished product, but there are also certain important steps in the manufacture of this product which materially affect these characteristics.

Preparing a Clear Product

A liquid soap prepared from coconut oil and containing 35 or 40 per cent of anhydrous soap will remain clear and transparent for an indefinite period at a temperature of or above 60 deg. F. If 40 or 50 deg. F. is maintained for a few weeks, however, soap crystals will gradually be forced out of the solution. These flocculent crystals, consisting largely of the soaps of lowest solubility, rise to the top rather slowly. Under these conditions the solution acts like one that is supersaturated, and by the agency of heat alone it is difficult to dissolve the crystals and thus re-form a clear solution. As long as the temperature stays at summer heat and the proportion of glycerine naturally occurring in the soap is sufficiently great, a liquid soap that

will remain clear and transparent can be prepared without the aid of any alcoholic clarifier. The first-named condition, however, is generally impracticable and the manufacturer is forced either to add glycerine or alcohol or else turn out a cloudy product. Glycerine is a valuable addition, since it has emollient properties; alcohol is of additional value because it commonly serves as the perfume carrier. Cane sugar, on the other hand, with its total lack of detergent properties, and its stickiness, should be used only in the cheapest goods.

Cause of Cloudiness

Another cause of cloudiness is the presence of insoluble soaps, more particularly the lime soaps. In contradistinction to the turbidity caused by the precipitation of soda and potash soaps, the insoluble soaps sink to the bottom of the liquid and must be separated by filtration or sedimentation rather than by the use of an alcoholic clarifier. If the manufacturer uses distilled water, practically no insoluble lime soap will be formed. The expense is generally prohibitive, however, and the best procedure is to use a good soft water, and if a clear product is wanted, to filter the liquid soap or permit it to settle in a tank.

Other Manufacturing Requirements

It is essential that a good quality of caustic potash be used. The commercial 88 to 92 per cent grade is dissolved in the proper proportion in a covered iron tank and the insoluble impurities permitted to settle. After a short while the clear, supernatant liquid can be siphoned off and used.

Operations in Liquid Soap Manufacture

Liquid soap manufacture may be said to involve two operations: Preparation of the soap paste and the solution of this paste in the liquid. The paste soap, which is made by the usual procedure of the soapmaker, resembles bleached petrolatum in appearance. If a pale liquid soap is desired, only the best raw materials are permissible and the soap paste should be made by the so-called cold process. This manner of treatment requires great care in order to insure complete saponification; otherwise the soap paste will gradually turn yellow.

Selection of Oil Important

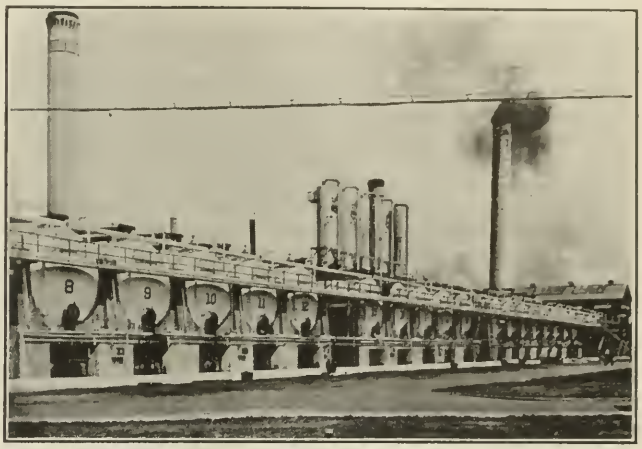
Since the oil used is one of the most important considerations, care should be taken in its selection. A good grade of coconut oil is of light color, free from objectionable odor, low in fatty-acid content, and contains practically no impurities. The ordinary Manila grade of oil, which is dark in color and has a strong empyreumatic odor, serves very well for the cheapest grade of liquid soap. Better qualities of oil are used, however, for the higher grade products. An oil of Cochin quality will furnish the base for such a product. A very superior liquid soap, practically water-white, clear and transparent, with an anhydrous soap content of 40 per cent and quite viscous, is made of an oil, the fatty-acid content of which has been reduced to about 5 per cent. Such an oil is pale yellow in color—ten yellow and one and a half red—on the color tester. Some soapmakers prefer to use refined edible oil for the highest grade goods, but this serves no better purpose than the cheaper oil and, in addition, is harder to saponify.

Brooklyn, N. Y.

Synopsis of Recent Chemical & Metallurgical Literature

Recovery of Gasoline From Uncondensed Still Vapors.—D. B. Dow, petroleum engineer of the Bureau of Mines, has recently completed a study of the different processes for the recovery of gasoline from uncondensed still vapors. This has been published in mimeographed form as Serial 2,344, *Reports of Investigations*, April, 1922. He estimates that 50,000,000 gal. of gasoline was recovered from uncondensed still vapors at refineries in 1921. Application of the system to all refineries would give a possible gasoline recovery by this method of 170,000,000 gal. yearly. Space limitation prevents giving a detailed account of this interesting, illustrated report, but an attempt is made in the following paragraphs to summarize briefly its salient features.

In the distillation in refineries appreciable amounts of the vapors are not condensed by the ordinary condensing equip-



BATTERY OF TWENTY CRUDE OIL STILLS CAPABLE OF HANDLING 10,000 TO 25,000 BBL. PER DAY. COSDEN & CO., TULSA., OKLA. (Photo by Bureau of Mines)

ment. The amount of vapor remaining uncondensed depends upon the following factors: (*a*) The amount of uncondensed vapors is proportional to amounts of gasoline produced. Other conditions being equal, more uncondensed vapor will be lost from a refinery which has increased the gasoline yield from crude by installing cracking stills than in a skimming plant which obtains only the gasoline present in the natural state. (*b*) A crude oil which gives a very volatile gasoline will lose more from uncondensed vapors than will a crude which contains gasoline of low volatility. (*c*) Summer losses due to uncondensed vapors are higher than winter losses. (*d*) The higher the temperature of the stream the greater will be the amount of uncondensed vapor. The stream temperature is directly dependent upon the temperature of cooling water and coil surface.

Experiments show that with stream temperatures exceeding 85 deg. F. the volumes of uncondensed vapors become increasingly large. Experimental data and plant data are given in the report which show effects of varying conditions of temperature.

A survey of 13 refineries of the United States which recover the gasoline from uncondensed vapors shows: A total crude charge for these refineries of 355,486 bbl. per day; a recovery of gasoline from uncondensed vapors of 128,651 gal. per day, which gives an average recovery of 0.444 gal. of gasoline per barrel of crude, or a recovery of 1.05 per cent of crude as gasoline which would otherwise be lost.

In operating a recovery plant on uncondensed vapors, one of the methods used for collecting vapors is as follows: A small vacuum is held on run-down lines where the vapors are

trapped off by means of goosenecks. This gas passes through traps which remove any condensate carried in the lines. The vacuum is held by either the intake of a compressor or in larger installations by means of an exhauster. When gas of high sulphur content is encountered, a unit for the removal of sulphur must be installed. This is accomplished by scrubbing the gas with a solution of caustic soda or suspended solutions of oxides of iron or lime.

In recovering gasoline from still vapors several different processes can be used: (*a*) The compression process is the more common, and consists of compressing the gas to a high pressure and cooling. This condenses the gasoline vapors and does not materially affect any permanent gas which may be present. (*b*) The absorption process consists of absorbing gasoline from the gas by passing it through a lower gravity distillate. When naphtha is used as the absorbent the naphtha is raised in gravity to the point where it may be marketed as gasoline. When a heavy gas oil distillate is used, the gasoline is separated from the gas oil by distillation. (*c*) Combination of the two methods is made use of when the gas after compression is passed through absorption towers.

Atmospheric temperature is an important factor in the production of gasoline from uncondensed refinery vapors. It is found that during winter months, due to more complete condensation of the vapors, the production of the "gas" plant will fall off to some extent. An unusual example of this is a certain skimming plant which produces about 6,000 gal. of compression gasoline daily through the summer months, but drops to as low as 500 gal. per day in the winter. Ordinarily, the difference is far less, but there is always a tendency for production to drop in cooler weather.

The cost of installing recovery plants will necessarily vary with different plants, depending on local conditions such as the distances between different stills which are sources of gas, the nature of gas, especially in regard to sulphur content, and the plant efficiency. However, a cost of approximately $15 per gallon of gasoline (daily capacity) should be sufficient. The operating cost of the gas plant is relatively low.

Refining of Corn Oils.—The preparation of edible oil from crude corn oil is described fully by A. F. Sievers and J. H. Shrader of the Bureau of Plant Industry, Department of Agriculture, in Department Bulletin 1010, which was issued during April. Extended experimental results are given on refining by treatment with caustic, bleaching with fullers earth and deodorizing with steam.

Two methods of refining average corn oil are found to be about equally satisfactory. The soapstock obtained in refining corn oil is soft and slimy, and special means are necessary to harden it. In one of the proposed methods a large excess quantity of caustic is used, while in the other the same result is obtained by adding soda ash after the break. A maximum temperature of 55 deg. C. is recommended in the refining of corn oil.

The value of the chemicals used and the oil lost in the treatment is 0.628 cent per pound of neutralized oil with method 1 and 0.564 cent with method 2, of which more than 80 per cent is represented by the loss of oil.

The oil is bleached with fullers earth according to the method generally used. Not less than 5 per cent of earth must be used. Corn oil does not bleach as much by this treatment as some of the other vegetable oils. The cost of the materials used and the oil lost in this bleaching process is about 0.22 cent per pound of bleached oil, of which approximately half represents the value of the oil lost.

The oil is deodorized by being blown with steam for several hours at temperatures above 400 deg. F. under reduced pressure.

The general arrangement of a refinery equipped to handle two batches of 25,000 lb. of oil a week is described and the passage of the oil through the several processes is discussed.

The cost of refining corn oil in such a plant as here described is found to be approximately 1.6 cents a pound. This cost figure was obtained by determining as nearly as possible the several charges for chemicals, oil losses, fuel, labor and overhead. The cost of the equipment, exclusive of the building, is estimated at $40,000.

Book Reviews

A DICTIONARY OF APPLIED CHEMISTRY. By *Sir Edward Thorpe*, assisted by eminent contributors. Revised and enlarged edition. Vol. 2, Calculi-Explosion. 717 pp., illustrated. New York and London: Longmans, Green & Co. Price $20.

The second volume of the new edition of Sir Edward Thorpe's Dictionary of Applied Chemistry is compiled by many of the same eminent contributors who have made the previous edition justly famous. There are some new names which would be known better in Great Britain than here. To the American reader that is, I think, a most disappointing thing about the admirable collection. There are not many names well known to the American chemical engineer, and this brings us to a point in which we find ourselves in agreement with the reviewer of the first volume. It is not unnatural that the contributors should be unfamiliar with American practice in chemical engineering, but from the American point of view it is one significant lack in the book.

The editor of such a series of essays must find himself in a very difficult position in endeavoring to accord proper weight to some of the contributions. To disagree with such weighting in certain instances is, of course, inevitable and merely the expression of an opinion that such and such a subject should not receive so much importance. In illustrating this particular point, there is a course in a certain college, part of which is devoted to a very special research problem carried out by the professor in charge while he was a student in Europe. The particular subject has very little to do with the general subject matter of the course but receives undue emphasis because of the peculiar make-up of the professor's ego. The Dictionary of Applied Chemistry is peculiarly fortunate in having a man whose experience is so wide and whose judgment is so sane as Sir Edward Thorpe. It would be difficult to find a man better qualified to proportion the space necessary for adequate discussion.

A general and gentle criticism may be suggested that too little space is given over to types of equipment and too much to theoretical chemical discussion. Specifically, it would seem to be more desirable in a Dictionary of Applied Chemistry to devote much more space to the subject of evaporation and evaporators and somewhat less to the general subject of carbohydrates. Evaporators as examples of chemical equipment have a tremendously wide use in almost every industry, and the dictionary discusses only the principles lying back of three designs now on the market. Considerable work, particularly in this country, has been done on the improvement of evaporator design, and it would seem that such discussion could be included desirably in the dictionary. Similarly, some of the discussion on carbohydrates has to do with rare sugars and their properties, the use of which is extremely limited and the general interest in which is rather negligible.

In like manner the American reader will be a little confused by the article on chlorine, for example, wherein the British methods of manufacture alone are taken up and no American operations are discussed. The technical discussion of the processes for chlorine manufacture is, however, entirely adequate.

It is to be sincerely hoped that the reader of this review will understand that my enthusiasm for this great work is very real. Consulting and operating chemical engineers who are not familiar with this would do well to look it up at once. In my experience, which has been confirmed by several acquaintances, the dictionary will supply a very adequate basis for a preliminary search on a subject upon which much information is desired and will frequently supply all the information that is necessary.

Some one has run off with the fourth volume of the older edition and I am extremely anxious to have the new edition come out and supply that missing link. That will only indicate my affection for the "mag. op."

CHARLES WADSWORTH, 3d.

LEHRBUCH DER METALLOGRAPHIE. By *Prof. Gustav Tammann.* Second Edition, 1921. 420 pp. 219 illustrations. Leipzig: Leopold Voss. 110 marks.

It cannot but be regarded as significant of a definite trend in metallography that in the new edition of "Lehrbuch der Metallographie," by Dr. Gustav Tammann of Göttingen, an entirely new viewpoint has been maintained. Like the first edition, it contains an extraordinary compilation of information concerning physical metallurgy. There are many of the chapters of the earlier edition which are again presented in substantially the same way; the additions are not alone in the form of appended or inserted chapters, but one finds the new material very effectively distributed throughout the whole treatise.

The new viewpoint is concerning the atomic arrangement in metals and alloys. Much of the actual data introduced is contained in an article entitled "The Chemical Properties of Alloys," which appeared in *Metallkunde* in September, 1921.

Tammann's own preface to the second edition may be read as follows: "The recent advance in the atomistics of crystalline substances does not deserve to remain unremarked in a domain which of late has leaned exclusively toward thermo-dynamic equilibria. Accordingly, the chapter on recrystallization is presented with a new atomistic principle and the chapter on the chemical and electrochemical properties is based on an atomistic concept of the arrangement of two kinds of atoms in a space lattice."

The metallurgist familiar with the metallography of useful metals might possibly expect a discussion of atomic arrangement to be uninteresting and impractical, but he will find these new chapters attractive because of the logical manner in which the "atomistics" of metals are associated with well-known properties—particularly chemical and electrochemical behavior—which, of course, constitute the basis of corrosion.

The mention of atomic arrangement instantly calls to mind the crystallograms made by the diffraction of X-rays by atomic planes. Prof. Tammann really has had available very little crystallographic data resulting from the application of Röntgen rays to metallography. Yet his inferences from other sources of information have been so accurate that in general they are in perfect accord with the X-ray data obtained in this country. At any rate, after reading the book the student will have a much more realistic impression of the state of existence of the metals in alloys and many words which now call to mind only microscopic appearance or physical properties will take on a mechanical significance.

The mechanism of solidification from the melt is lucidly described, and even if one does not feel inclined to agree entirely with the presentation, it nevertheless is an attractive hypothesis. Prof. Tammann says that the atoms of the melt are isotropic, but become anisotropic upon cooling. This change is prerequisite to their alignment in a space lattice. The rate of formation of the anisotropic nuclei and the rate of crystal growth from the nuclei determine the grain size. In the case of amorphous glasses the rate of formation of nuclei is so very low that before an appreciable number are started the temperature may be dropped to a range where none whatever form. Reheating in such cases either starts new nuclei or may reduce the viscosity so that an ordinary liquid results.

It is in the discussion of solid solutions that the matter of atomic distribution is chiefly stressed. The picture of the inherent nature of solid solutions offered in this country by one of the present writers is corroborated entirely by Prof. Tammann. The atoms of the solute replace atoms of the solvent in its lattice with only a change in the size or parameter of the lattice. Upon solidification of a binary solution the atoms of both metals betatke themselves to certain lattice positions, but they are not arranged in the same proportion in all parts of one grain nor are two adjacent grains necessarily of the same constitution. Above the recrystallization range of temperature a rearrangement or "place-interchange" occurs, and the two kinds of atoms become distributed as symmetrically as possible. When several modes of symmetrical arrangement are possible for a given composition, that one which gives the greatest number of atomic lines containing both kinds of atoms is built up. By this method of arrangement the smallest possible portion of the lattice will show the average composition of the whole mass of alloy. Obviously there are some ratios which will produce relatively simple distributions, notably in the regular system 12.5, 25.0, (37.5), 50.0, (62.5), 75.0 and 87.5 atoms per cent.

The proof of this is ingeniously shown by the very abrupt change in electrochemical behavior in many alloys at these compositions. Reagents which vigorously attack one constituent and are inert toward the other usually show action up to a certain content of the more noble metal and almost no action for higher concentrations. A great variety of reagents in contact with many alloys are cited and the results are tabulated. As an example, nitric acid does not attack silver-gold alloys with more than 50.0 atoms per cent of gold, but completely removes all the silver from those with less than 37.5 atoms per cent. Between these percentages of gold content the action is linear with the composition. The 25.0 per cent composition limit holds for the action of weak oxidizing agents and palladium chloride on the gold-copper series. (Palladium chloride is decomposed by the gold-silver series up to 50.0 atoms per cent.) The matter of valence is most important in the location of these composition limits, and this fact is very logically explained. If the atoms of the two metals were distributed in the lattice at random, we should have the protective action of the noble metal conforming to the law of probability and there would be no abrupt steps in the function. This "composition-for-reaction-limit" study has resulted in what is probably the most plausible explanation of the absorption of hydrogen by palladium.

The possible space distributions for various compositions are comprehensively charted in the book. It is interesting to note that the regular arrangement of two kinds of atoms in a solid solution was discovered by X-ray analysis within the past year in this country. There is, of course, no very simple space distribution for a composition corresponding to 37.5 atoms per cent (ratio 3 to 8), and indeed this value rarely marks a reaction limit. Metals deposited simultaneously from an electrolyte do not possess the regular distribution of the two kinds of atoms (unless heated to the recrystallizing temperature) and consequently do not show the normal composition limits for reaction, but, like the amorphous glasses, do not possess this interesting property.

In discussing the possibility of the formation of an uninterrupted solid-solution series between two metals Tammann states definitely that they must both have the same type of space lattice. Since he accepts the evidence for the usual statement that copper and manganese, chromium and nickel, and alpha iron and nickel form completely isomorphous series, he includes all these metals in the face-centered cubic series. Actually it has been proved that chromium and alpha iron are body-centered cubic, unlike nickel, and that manganese is not isometric at all, but is of a complex type, probably hexagonal. In this country one of the present writers has shown that certain compositions in these so-called continuous solid-solution series are built up of the two distinct crystal types belonging to their component metals.

It is to be regretted that Prof. Tammann had not available a more complete knowledge of the verified space lattices of the elements, such as given by Hull. The choice of nomenclature used in connection with the description of the known types of isometric lattices of metals is unfortunate. The simple cubic is called the 8 point, the body-centered the 9 point, and the face-centered the 14 point. These numbers refer to the actual number of lattice points in any way involved in the arbitrarily chosen elemental cube of the structure. As a matter of fact, the three types respectively contain 1, 2 and 4 atoms per unit cube. The descriptive names used in English writings on atomic structure are certainly much better chosen.

A point which appeals to English-speaking readers is the remarkable freedom of the work from the ponderous, involved style found so frequently in German scientific writings. Altogether, the book is an admirable presentation of the physical chemistry of metals and the metallographist cannot shun the new viewpoint without hampering himself in his attempt to generalize the properties of metals.

EDGAR C. BAIN and STANTON UMBREIT.

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Bills Before House Embody Acceptance of Ford Muscle Shoals Offer

The recommendations of a majority of the members of the Committee on Military Affairs of the House of Representatives in the matter of the Henry Ford proposal for the Muscle Shoals property is embodied in a bill introduced June 5 by Representative McKenzie, acting chairman of the committee.

The bill authorizes the sale of Plants No. 1 and No. 2 and the Waco quarry to Henry Ford and the lease of dams 2 and 3, including power houses and all hydro-electric and other equipment except the locks, for a period of 100 years.

Included in the property of the sale are all the lands, buildings and equipment of plants 1 and 2, the right to use all the patents, processes and designs which have been acquired and the sulphuric acid units now in storage on the premises. Mr. Ford would not be bound, however, to operate Plant No. 1 as a nitrogen fixation plant. The payment of $5,000,000 may be spread over 5 years, the first payment of $1,000,000 to be made on acceptance of the offer.

The annual rental for the plants is fixed at 4 per cent of the actual cost of acquiring land and flowage rights and completing dam and power houses. This amount does not include expenditures incurred prior to the approval of the proposal. Rental payments are to be made annually, the amount for the first 6 years after the development of 100,000 hp. being fixed at $200,000 per year. The annual rental for dam No. 2 is placed at $35,000 per annum, upkeep to be borne by the company.

Would Bind Lessee to Work on Fertilizers

The bill specifically states that the company must agree to manufacture commercial fertilizers at Plant No. 2 or such other plants as may be constructed, the annual production to have a nitrogen content of at least 40,000 tons of fixed nitrogen—the present capacity of Plant No. 2. It is also stipulated that the company will determine by research whether there may be produced on a commercial scale fertilizer compounds of higher grade and at lower prices than farmers and other users of commercial fertilizers have in the past been able to obtain, and to determine whether in a broad way the application of electricity and industrial chemistry may accomplish for the agricultural industry of the country what they have economically accomplished for other industries. If such methods be found they are to be reasonably employed.

As will be noted, the 100-year lease period which was the basis of much opposition to Ford's original proposal is retained, as is the original purchase price.

The main change in the terms of the offer is the exclusion of the Gorgas steam plant. Mr. Ford has expressly stated that he will stand or fall on his offer and that the exclusion of the Gorgas plant would be interpreted by him as the rejection of his offer.

Additional Bills

The minority of the committee's membership, which favors the unqualified acceptance of Mr. Ford's offer as amended on May 31, will submit its bill and report the latter part of the week. The majority report on its bill also will be submitted at that time. Two bills already have been introduced, proposing the acceptance of the Ford offer. One was introduced by Representative Wright of Georgia, a member of the committee but acting independent of the minority. The other was introduced by Representative Almon of Alabama, in whose district the property is located.

The Senate amendment to the War Department appropriation bill, by which $7,500,000 would be granted for the completion of Dam No. 2, aroused some discussion in the House. Several members argued for its direct consideration by the House instead of by conference. The point at issue seemed to be an uncertainty in the minds of the Representatives as to the bearing of such an appropriation on the lease proposals which are now before the House. Representative Byrns of Tennessee held that the amendment would not affect the consideration of the lease offer. Others, notably Representative Green of Vermont, who is a member of the Military Affairs Committee, felt that a question of government policy is involved. The amendment was sent to conference, with prospects of open debate on the floor of the House upon its return.

Ford's "Secret" Fertilizer Process May Be Federal Phosphorus Co.'s Method

According to recent reports, the Federal Phosphorus Co., headed by Theodore Swann of Birmingham, is contemplating the removal of its plant from Birmingham to Jacksonville. T. L. Long, representing Mr. Swann, recently appeared before the city commission of Jacksonville and asked that Jacksonville give the company power concessions for the establishment of a factory on what he intimated would be a 10-acre site.

The electric furnace process for the manufacture of phosphorus from phosphate rock, coke, sand and iron borings[1] is supposed by many to be the "secret" electrical process to which W. B. Mayo, Henry Ford's chief engineer, referred when before the Senate committee, when he said that Ford could make cheaper and better fertilizer for the farmers of the nation. Certainly Mr. Long's statements to the Jacksonville commission gave this impression very pointedly.

It is claimed that the new process will give from 35 to 40 per cent of plant food, compared to about 14 per cent secured from phosphate rock by the old acid treatment.

Jacksonville's power rate is 2 cents per kw.-hr., with a downward sliding scale for large consumers. While the commission has not yet gone into a full consideration of the application it will probably be considered in the near future.

Edison Working on Potash Extraction

Some light on experiments which it is rumored are being made by Thomas Edison with potash, from deposits in east Tennessee, is shed by a letter from Mr. Edison to State Geologist Wilbur A. Nelson and made public by Mr. Nelson. The letter dated May 16, follows:

> Your letter of May 10 has been received. Since I got some of the Cartersville potash slates the experiments have never ceased. One line of experimentation shows very promising results. The only trouble is, Can we manufacture on a large scale so as to compete with German potash? So far, it looks as if we could and also go them a little better. If we cannot quote a price at which they (the Germans) cannot sell, it will help the farmer very little. What is required is that he can get it very cheaply.
>
> Can you send me a colored geological map of the region, say covering 250 miles in diameter, with Muscle Shoals as a center? If this map could not be furnished as a single map, it would do in sections.

Mr. Nelson explains that the Cartersville slates are named from the town of Cartersville, Ga., near which they are found. The deposit extends into Tennessee.

Testimony Before Dye Investigation Committee Ends With Defence of Textile Alliance

Hearings before the Senate judiciary sub-committee conducting the dye investigation were concluded June 3 when A. M. Patterson, president of the Textile Alliance, appeared to rebut certain statements made by W. Paul Pickhardt of Kuttroff, Pickhardt & Co. At the close of this session Chairman Shortridge announced that at the present time there was no intention of holding further hearings and that the committee stood adjourned to meet again at the call of the chairman.

Says Importer Hindered Alliance

Mr. Patterson attacked testimony delivered previously before the committee by William Paul Pickhardt, of Kuttroff, Pickhardt & Co. and criticised that firm for hindering in every way possible the efforts of the Textile Alliance, as the officially designated agency of the United States Government, to secure German dyes needed by American dye-consuming industries.

The German cartel had offered to sell its dyes to the Textile Alliance as a private concern, Mr. Patterson testified, but this offer was immediately rejected. The Alliance, he said, never had attempted to substitute German dyes for American dyes in use by consumers.

Petitions "ostensibly signed" by thirty mills which had been presented to the Senate Finance Committee at hearings held by that committee two years ago, Mr. Patterson said, had been prepared and circulated by Kuttroff, Pickhardt & Co., in "spite of numerous denials." "As a matter of fact," he added, "this was nothing more than a part of Kuttroff, Pickhardt & Co. propaganda."

"In carrying out our task for the government and the consumers," he said, "we had assistance of many importers, particularly Mr. Metz, but never of Kuttroff, Pickhardt & Co."

The petition in question, he continued, had been a "dead issue" for two years and is pertinent to the present discussion only because Mr. Pickhardt had introduced it in his previous testimony before the committee. "It purports to be a spontaneous expression of opinion of consumers, but it is not what it is supposed to be," he added. The petition protested against importation of dyes through any other than the "regular commercial channels."

The Reparation Commission had refused to deal with the Textile Alliance, or any importer as a private concern, the committee was told. The Department of State had terminated the arrangement whereby the Alliance was its officially designated agent to receive these dyes. This action was taken because the Department of State believed it did not have the power to continue the Alliance or any other organization as its agent. The Reparation Commission had notified this country that unless it designated some agency to receive such dyes as accrued to it under the treaty it could not continue to supply them after June 30, 1922.

"If nothing is done in the face of this situation," Mr. Patterson said, "the German monopoly will again be a monopoly as far as the 10 per cent of dye consumption needs which we must import."

Pickhardt Presents German Offer

An offer of the German cartel has been made by him to the State Department and the Commerce Department, Mr. Pickhardt told the committee. This offer provided that the German cartel should supply the United States the needed quantity of dyes, not covered by the reparation dyes, at prices as low as if they had been secured under the present arrangement.

Chairman Shortridge questioned the efficacy of such an agreement and asked how it would be enforced. Mr. Pickhardt said he assumed it would be enforced in the same manner the treaty provisions were enforced. He denied a statement by Chairman Shortridge that the German cartel was controlled by the German Government.

Mr. Patterson declared that it was distinctly to the benefit of the American people to receive the reparations dyes and expressed the view that the Department of Commerce should be designated as the agency to receive them. He stated that unless the government takes action, the supply will be cut off on the thirtieth of June.

There followed some discussion between Mr. Patterson and Mr. Pickhardt as to what would be the loss to the country in such event. Mr. Pickhardt repeated his previous statement that no loss would be incurred by the consumer inasmuch as the German cartel had authorized him to state that it would agree to supply at low prices whatever dyes might be lost through termination of the present arrangement. Mr. Patterson insisted that this proposal did not solve the problem. The Textile Alliance did not wish to continue as the officially designated importing agency for these dyes and it had repeatedly urged that this be taken over by the government itself, but that in all events, in order to safeguard consumers' interests, some action that will make continued receipt of the dyes certain should be taken prior to June 30.

Table of Dye Prices Shows Steady Decline

Of interest in connection with the original purpose of this investigation—the alleged existence of an American dye monopoly, is a table recently issued by the Synthetic Organic Chemical Manufacturers' Association. The fact that no substantiation of the monopoly charges developed during the hearing is strengthened by the additional evidence of competition shown in the steady decrease in the price of nearly all American dyes in the past five years.

The table comprises 67 dyes of American manufacture, the tonnage production of which aggregates over 82 per cent of the total American production for the calendar year 1920.

It is particularly worthy of note that the depression in the prices of American dyes has taken place over a period during which competing dyestuffs of German manufacture were prohibited entry. The table shows the average price of each dye, each year, for a period of approximately five years, from January 1, 1917, through April 27, 1922. It also shows the percentage of decrease in the American prices over this period.

The vividness of these reductions is particularly emphasized in connection with the reduction in prices of the following colors produced in large quantities:

Indigo, produced by 12 American manufacturers, and which in 1917 had an average price of $1.42 per lb., on April 27, 1922, sold for 30 cents per lb., a decrease of 79 per cent.

Sulphur black, produced by 3 American manufacturers, and which sold in 1917 at 60 cents per lb., on April 27, 1922, sold around 18 cents per lb., a decrease within that period of 70 per cent.

Direct black, EW, produced by 14 American manufacturers, and which sold in 1919 at $1.04 per lb., on April 27, 1922, sold at 42 cents per lb., a decrease of 60 per cent.

Malachite green, produced by 6 American manufacturers, and which sold in 1917 for $6.28 per lb., on April 27, 1922, sold for $1.50 per lb., a decrease of 76 per cent.

Declines in the prices of other dyes range downward to one per cent in the price of acid yellow G. This dye, produced by two American manufacturers, was not put on the market in commercial quantities prior to 1921, when its average price was $1.21 per lb. The market price of this dye on April 27, 1922, was $1.20 per lb.

The comparatively small decreases in the prices of these newer American dyes as against those which have been produced for a longer time seems to indicate clearly that increased efficiency and lower costs result from extended experience in manufacture.

Japanese Trade in Fertilizers

Fertilizers imported into Japan during the fiscal year ended March 31 were valued at 121,800,000 yen. This was a decrease of 110,000,000 yen compared with the preceding year. The export trade also suffered a decline and in the past twelve months amounted to only 320,000 yen. This figure was over 2,000,000 yen less than in 1920.

Sentiment Strong for Dye Embargo—Manganese Put on Free List

While all plans had been made by Senate leaders to dispose of the dye embargo matter before the week of June 5, the discussion was permitted to go over for a week on the insistence of Senator King that he had been led to believe that paragraph 26 of the chemical schedule would be considered separately. Senator McCumber is at a loss to know just how such an impression was created, but in his desire to accommodate Senators and give ample time for such investigation as they are desirous of making, he granted the extension of time. It is regarded as practically certain, however, that the dye embargo will have been voted on before the end of the week of June 12.

At the time of this writing, it seems practically certain that the committee has the votes to retain the embargo provision in the bill. It is significant that Senator King is the only Democrat who has spoken against the measure. The Democratic opposition is lukewarm and it is known that some members of that party will vote for the embargo.

Perhaps the most significant development in recent weeks in the embargo situation came when Senator Frelinghuysen revealed that President Harding is squarely behind this proposal. Senator Frelinghuysen has led the fight for the embargo and in addition to his very convincing speeches on the floor of the Senate is credited with having convinced Senator Moses that there is more merit in the proposition than the latter formerly believed. The chances of the embargo were improved greatly when Senator Moses withdrew his active opposition.

Chemical Warfare Drawn Into Discussion

Gas was brought into the debate only once. Senator Borah, in condemning a continuance of chemical warfare activities, admitted that other nations are going ahead with their scientific studies of the application of gas to warfare. Senator King attempted to prove that there was no connection between dyes and the national defense. His attention, however, has been called to the British report which points out and proves the exact part which the German dye plants contributed to military prowess. The point also will be made in defense of the embargo that the Chemical Warfare Service of our own army, without any thought of its application to a dye embargo, long has been studying the exact details of converting specific American dye plants to military uses in time of war.

King's Attack Without Influence

Senator King's five-hour set speech and his numerous but less lengthy tirades against the domestic dye industry in no way influenced the vote on paragraph 26, which was adopted just as soon as an opportunity was offered for the vote. In the course of the discussion Senator McCumber pointed out that Republicans do not believe in embargoes, but that an exceptional situation had arisen—so exceptional that even a Democratic President had recommended a chemical and dye embargo.

Paragraph 25, covering dyes, which was adopted some time ago, was returned to in order to permit Senator King to offer an amendment which was rejected, placing the duties on dyes in that paragraph at 50 per cent ad valorem, and 3½ cents per pound on dyes valued at not more than 10 cents a pound and 30 per cent ad valorem and 7 cents a pound on those valued at more than 10 cents a pound. The paragraph was then adopted as recommended by the committee.

Senator King offered an amendment changing from 60 per cent ad valorem and 7 cents per pound the duties in paragraph 26 as follows: 35 per cent ad valorem and 3 cents per pound on those valued up to 25 cents a pound; 35 per cent ad valorem and 5 cents a pound on those valued up to 50 cents a pound, and 35 per cent and 7 cents a pound on those valued at more than 50 cents a pound. The amendment was rejected after debate.

Senator King opposed the committee rates, saying they were the same on intermediates as on finished products and would amount to duties of 400, 500 or 600 per cent and on other allied products 100 per cent. He objected to the same duty on dyes of varying prices. He had no objection particularly to the ad valorem duties, except that they were too high, but criticised especially the specific rate. His amendment readjusting the duties was rejected by a vote of 18 to 40, and the committee rate was than approved.

Senator King offered an amendment to strike out the provision that any article in paragraphs 1, 5, 35, 37, 56, 63, 79, 1578, 25, 26 and 1546 shall be assessed for duty or exempt from duty under paragraphs 25, 26 or 1546. The effect of this amendment would take out medicines and compounds from the paragraph giving the articles a duty of 20 or 25 per cent. Senator Smoot opposed the motion, saying the duties were recommended by the Tariff Commission, and the King amendment was rejected. The Utah Senator also offered an amendment fixing the highest instead of the lowest strength as the standard for dyes. It was opposed by Senator Smoot, who said the change would work an injustice. Senator King admitted the amendment might work an injustice and withdrew it with the understanding that he might renew it after consultation with those familiar with the dye industry. Paragraph 26 was then adopted.

Manganese Put on Free List

The Senate again overrode its Finance Committee on the amendment which carried manganese ore to the free list. The vote was 19 to 35. The effect of the vote was to restore to the bill the House rates of 1 cent a pound on manganese ore or concentrates, carrying in excess of 30 per cent metallic manganese. The amendment was offered by Senator Nicholson of Colorado, who delivered a long speech in behalf of protection to the American manganese industry, which he said had been developed during the war and which should be protected against deposits of foreign countries which were worked more cheaply than in this country. The debate largely revolved around the question as to whether American deposits of manganese were sufficient to meet the requirements of the steel industry.

Potash Paragraph Faces Fight

It is becoming increasingly apparent that the duties on potash will not be accepted by the Senate without a fight. Propaganda against the duties is afoot and farmers in large numbers are writing to their Senators asking that they oppose the duty.

Some of those favoring the potash provision of the tariff bill contend that the German syndicate is back of the propaganda. On the other hand, the paragraph has the strength which goes with hearty committee endorsement and it squares with the Republican protection policy.

A new element has been interposed in the situation by the promising discoveries of potash in Texas. The farmers and business men in southwestern Texas are acting in a united and active manner in their support of the potash duty. Each member of the Senate and of the House of Representatives has been mailed a brief signed by "owners of potash beds in the State of Texas," in which the point is made that foreign producers have effected an international combination in restraint of trade and that the consumers in the United States will suffer in the end unless American sources of potash are developed.

Chemical Warfare Service Appropriation Increased in Senate Amendment

The Senate passed the War Department appropriation bill with the committee amendment increasing the appropriation for the Chemical Warfare Service from $500,000 to $750,000. Senator Borah of Idaho opposed the increased appropriation on the ground that it was not keeping faith with the armament conference in barring poison gas. By a vote of 46 to 22 the Senate adopted the increased appropriation and the measure now goes to the House for action on this and other Senate amendments.

An amendment was proposed by Senator Wadsworth of New York, chairman of the Military Affairs Committee, providing for the employ of draftsmen, chemists and chemical engineers in the office of the chief of the Chemical Warfare Service at Washington.

Mellon Institute Annual Report Shows Value of Scientific Research to Industry

The ninth annual report of the Mellon Institute of Industrial Research of the University of Pittsburgh brings out the extent of the valuable experimental work that is being conducted by the Institute. Although the Institute has never aspired to largeness in size, there are now forty-nine industrial fellowships, and additional fellowships will begin operation just as soon as the necessary facilities can be provided.

The total amount of money contributed by industrial firms to the Institute for the eleven years ended March 1, 1922, was $1,995,922. During the eleven years the Institute itself expended approximately $477,600 in taking care of overhead expenses. Eleven of the fellowships have been founded by associations, thus enabling the Institute to be of direct service to groups of industrial concerns instead of to individual companies.

Demonstrating Value of Research to Industry

By the application of its system, the Institute has been able to demonstrate to American manufacturers and associations that industrial research, properly carried out, is profitable to them. It would be interesting to give here a statement concerning the financial gains which have been derived by donors as a result of the Institute's activities in their behalf. The executive staff is not privileged to release this information at the present time; but it may be noted in passing that 85 per cent of the problems accepted by the Institute for study from 1911 to 1922 have been solved satisfactorily from the donors' standpoints.

Among the investigations completed and under way at the Institute may be mentioned the following: Physical properties of glass; bread technology; citrus products; electrical precipitation; smoke investigation; pressed glassware; chemistry of petroleum; manufacture of carbon dioxide, carbon monoxide, hydrogen and nitrogen; composition flooring; fractional distillation; hydrometallurgy of copper; olefine gases; flotation of ores; dental cements; chemistry of laundering; natural gas; refractories; byproduct coking; fiber containers; heat insulation; glue; insecticides; food and beverage flavors; inks; protected metals; sulphur, and galvanizing.

During the past year the Institute has contributed to science and technology two books, forty research reports and thirty-one other scientific papers and has issued thirty-five United States patents.

Department of Commerce and Engineering Societies Co-operate on Standardization

At the request of Secretary of Commerce Hoover, the American Engineering Standards Committee will undertake at once a canvass to determine what simplification in manufactured products is most needed and most desirable. This canvass will be conducted through the engineering and technical bodies having representatives on the committee or co-operating in its work. The survey of simplification or standardization needs and possibilities will extend into almost every industry in America.

This assignment to the American Engineering Standards Committee is one of Mr. Hoover's steps to retrieve for American industry part of the waste which was pointed out by the well-known report on waste in industry which was made by a committee also appointed by Mr. Hoover while he was chairman of the Federated American Engineering Societies. The latter committee found that waste in industry was due largely to an overmultiplicity in number of products as well as to inefficiency in processes.

There has been considerable discussion as to what should be the relationship between the simplification work of the Department of Commerce and the standardization work of the American Engineering Standards Committee. An arrangement has been made for permanent exchange of representatives between the two organizations so that there may be the closest possible co-operation between the Commerce Department's division of simplified practice and the American Engineering Standards Committee, and duplication or overlapping will be avoided.

Former Alien Property Custodian Would Welcome Investigations of Activities During War

During the debate in the House on war frauds, Representative Garrett of Tennessee read a letter from former Attorney-General Palmer, expressing the hope that Congress would appoint a committee to investigate all contracts and expenditures made by the War and Navy Departments and the Alien Property Custodian. Mr. Palmer said charges and insinuations now being made with respect to the Chemical Foundation and the Bosch Magneto case have been repeated many times, although they were investigated by two Senate committees, but that until final disposition of German property is made by the Alien Property Custodian and Congress it was expected that these charges would be constantly reiterated. He stated that the Bosch Magneto Co. was German to the core and that before the United States entered the war its management violated our neutrality in a most flagrant fashion. He explains that sale of the company by the Alien Property Custodian was approved after careful investigation as to the adequacy of price and character of purchasers.

Defends Chemical Foundation

Mr. Palmer pointed out that the Chemical Foundation is a non-profit corporation, formed to take over nearly 5,000 American patents owned by Germans in the chemical industry, which had been originally taken out by Germans to make it impossible for the chemical industry to develop in this country.

"Today by reason of the Alien Property Custodian's plan of Americanizing these German patents and distributing them to the American producers through a semi-public institution like the Chemical Foundation, having for its purpose only the development of the chemical science in America, it has become apparent that the world can never again be caught in the clutches of a German control of the chemical industry." said Mr. Palmer. "I have no hesitation in saying that the biggest achievement of the Alien Property Custodian for the benefit of our country and its future welfare and security was the formation of the Chemical Foundation and the sale of these German patents to it. The Germans recognize its transcendent importance and would now resort to any device to set aside that sale and have the patents restored finally to their German owners in the hope that they could thus again dominate the chemical industry of the world. Their present plan seems to be to discredit the Alien Property Custodian and thus persuade the government of the United States, either through Congress or the executive departments, to take such action as will restore to Germany the stranglehold upon American industry and commerce in many important lines of industry which the Alien Property Custodian loosened as a part of the government's policy in prosecuting the war."

Bureau of Mines Investigates Sands Used in Aluminum-Alloy Foundry Practice

The Bureau of Mines, as one of the governmental agencies directly co-operating in a general research of all foundry sands organized by the American Foundrymen's Association and the National Research Council, is collecting data on sands for molds and cores in aluminum-alloy foundry practice.

There is pressing need of collated information on sands used in aluminum-alloy founding, and it is hoped, as a result of the investigation, to aid in disseminating knowledge on the subject. A questionnaire is being sent by the Bureau of Mines to aluminum-alloy foundries in the United States in order to obtain data to be used in the preparation of a report. It is possible that some foundries of this kind are not upon the bureau's mailing list, and it is hoped that any such plants that do not receive the questionnaire will apply for one. While the replies to the questionnaire will be summarized for publication, the contents of individual communications will be held strictly confidential. Communications in regard to the matter should be addressed to R. J. Anderson, metallurgist, U. S. Bureau of Mines Experiment Station, Pittsburgh, Pa.

International Congress on Liquid Fuels to Be Held in Paris in October

An international congress for the discussion of general problems in the rapidly growing field of liquid fuels is being arranged by the Société de Chimie Industrielle. The meeting will be held in Paris during October, 1922. Prof. Paul Sabatier will preside over the sessions, which will be devoted to discussions on two main topics—namely, terminology for liquid fuels and methods of analysis. The organizers of the congress have asked a number of specialists in the liquid fuel industries for suggestions as to the detailed points to be discussed. All the suggestions are to be grouped into six sections as follows: Petroleum, shale oil, lignite and peat, tar and benzene, alcohol and vegetable oils.

The honorary committee of the organization consists of Prof. Paul Sabatier, of Toulouse, president, Profs. D. Bertholet, le Chatelier, Lindet and Moureau. The active committee is composed of Profs. d'Arsonval, Baumé, Brylinski, Charpy, Duchemin, Demarais, Gerard, Mailhe, Matignon and Willems. The committee feels that the present interest in liquid fuels in America will warrant the attendance of numerous Americans and extends a cordial invitation to those interested. A liquid fuels exposition will be held in Paris during the entire month of October in connection with the congress, the exact date of which has not been definitely announced.

Enamel Division, American Ceramic Society, Plans Research on Enameled Cast Iron

The Enamel Division of the American Ceramic Society is undertaking an investigation of cast iron for enameling purposes. At a recent meeting of the committee delegated with this research, a comprehensive program was drawn up, particular attention being paid to the blistering of enamels applied to cast iron. This investigation will be conducted in co-operation with the enameled metal section of the Bureau of Standards and it is hoped to actively interest all cast iron enamelers of the division.

The research sub-committee on sheet iron and steel has planned an investigation of the warpage and buckling of iron and steel sheets in the enameling process. It is planned to conduct the preliminary studies at the Bureau of Standards and to follow this by co operative work in several of the enameling plants engaged in the enameling of flat sheets.

The bylaws of the division have been revised to conform with revisions in the rules of the society.

International Union of Pure and Applied Chemistry Announces Topics for Discussion at Lyon

Announcement is made of the principal subjects to be discussed by the congress of the International Union of Pure and Applied Chemistry which is to meet in Lyon, France, June 27 to July 2. Among the topics to be considered are the following: Chemical elements, reform of nomenclature, bibliographic abbreviations, unification of chemical abstracts, international institute of chemical standards, thermochemical standards, tables of constants, international laboratory for food products, national and international laboratories for ceramics and for combustibles, international patents, industrial hygiene in the chemical industry.

Several points will be laid before the congress for further study, among which are: Signs of potentials of electrodes, international definition of the term ceramics, conservation of foods by physical and chemical processes.

Helium Appropriation Reduced

The recommendation of the Military Affairs Committee on the helium provisions of the War Department appropriation bill was adopted by the Senate. The committee recommended the reduction of the appropriation for experimental work on helium from $400,000 to $300,000, as proposed by the House. In spite of opposition from Senator Sheppard of Texas, the Senate adopted the recommendation.

American Electrochemical Society Officers Appointed—Symposiums Planned for Spring Meeting

At a recent meeting of the board of directors of the American Electrochemical Society, Dr. J. A. Mathews was appointed to fill the unexpired term of C. G. Schluederberg as vice-president and George K. Elliott was appointed to fill the unexpired term of C. G. Fink as manager. F. A. J. FitzGerald was reappointed chairman of the publication committee and H. A. Hinckley was appointed chairman of the membership committee.

William G. Horsch of the Massachusetts Institute of Technology was appointed chairman of a committee to arrange a symposium for the spring, 1923, meeting on the subject of Electrode Potential. Members of the society and others desiring to participate in this symposium are requested to communicate with Professor Horsch. The symposium will cover the following studies: Reversible electromotive force, overvoltage, ion activities and dissociation, electro-titration and pH determinations.

The Electrothermic Division has prepared a symposium on industrial heating for the fall meeting at Montreal, Sept. 21 to 23.

British Parliament Moves to Protect Trade Marks

An important bill amending the present merchandise marks act, which prescribes the requirements for the marking of goods imported into the United Kingdom, has been submitted to the British Parliament.

Part 1 of this measure relates to merchandise marks and provides that an order may be made requiring an indication of origin if the Board of Trade is of opinion that a false impression as to the origin of any class of imported goods is likely to arise. Section 2 of part 1 authorizes the Board of Trade to prohibit the application to imported goods of any national or other public device reasonably calculated to lead any person to believe that the goods are of British origin. Section 4 prohibits the importation into the United Kingdom of goods to which there is applied a forged trade mark or false trade description, or to which a trade mark is falsely applied within the meaning of the act and of any goods to, or in connection with which, a national or other public device is applied in contravention of the provisions of an order under the act, unless the device is accompanied by an indication of origin.

Gas and Fuel Section New Feature of Next American Chemical Society Meeting

A gas and fuel section of the American Chemical Society has been authorized for the next meeting, which is to be held in Pittsburgh the first week in September. Among other subjects discussed will be the general topic: "Combustion." This special symposium will be under the chairmanship of Prof. R. T. Haslem of Massachusetts Institute of Technology. It will include a program of papers on chemical methods underlying fuel utilization.

Officers of the new section are: Chairman, Dr. A. C. Fieldner, Bureau of Mines, Pittsburgh, and secretary, R. S. McBride, Colorado Building, Washington. Any members of the society having papers to present at the meetings of this section should forward them in full or in abstract form to the chairman or secretary or should notify these officers regarding their intention to prepare the paper later.

Safety Institute Starts Film Service

The Safety Institute of America has inaugurated a safety film service for members and others particularly interested, it is announced at the headquarters of the Institute, 141 East 29th St., New York City. This service was made possible by an initial gift from the department of safety, sanitation and welfare of the United States Steel Corporation. The Safety Institute will endeavor to build up its collection of moving pictures to the proportions of its stereopticon safety slide collection, which is now probably the largest in existence.

Explosion in Synthetic Ammonia Plant of Atmospheric Nitrogen Corporation

Four persons were injured in an explosion on June 11 at the new Haber process plant of the Atmospheric Nitrogen Corporation at Solvay, just west of Syracuse, N. Y. Officials of the Allied Dye and Chemical Corporation, of which the Atmospheric-Nitrogen Corporation is a subsidiary, were not able to explain the cause of the accident or to estimate the damage. It was stated, however, that operation will be normal within a few days. The damage was confined to the interior of the process building, the walls remaining intact.

Tungsten, Molybdenum and Vanadium Discussed at New York Section, A.C.S., Meeting

Tungsten, molybdenum and vanadium, metals which are immediately associated with high-speed tool steels, were discussed from a different angle at the New York Section of the American Chemical Society on June 9. C. W. Balke, of the Fansteel Products Co., and B. D. Saklatwalla, of the Vanadium Corporation of America, presented papers dealing with the preparation of these metals in a pure state and their applications other than in the special steels.

One of the most interesting points brought out by Dr. Balke was his mention of the work that is in progress on the metal tantalum. He showed samples of tantalum powder, rods and plates and predicted that this unusual metal will find unique uses in the chemical and other industries, due to its remarkable resistant properties. It was stated that tantalum is absolutely unaffected by boiling aqua regia or any other acid except hydrofluoric. This property makes it ideal for the manufacture of dental instruments. It absorbs gases with avidity, taking up 750 times its own volume of hydrogen. This property is desirable in wireless bulbs where high vacuum is essential.

The preparation of pure tungsten and molybdenum is very similar, the only differences in the process being due to the lower melting point of molybdenum.[1] Tungsten melts at 3,350 deg. C., the highest melting point of any known metal while molybdenum melts at 2,500 deg. C. The extremely high fusing temperature of tungsten makes it unique among the metals in that it is never melted in the course of its preparation and exhibits properties at room temperature which correspond to those of ordinary metals at very low temperatures. At higher temperatures tungsten has the highest tensile strength and the lowest coefficient of expansion of any known metal.

The metal is prepared from wolframite, an iron, manganese tungstate, by fusion with soda ash in a reverbatory furnace and the formation of soluble sodium tungstate. This is leached from the fusion mass and converted to the oxide. The physical and chemical properties of the oxide have a decided effect on the grain size of the metallic tungsten prepared from it. A fine fluffy oxide yields a fine metallic powder, while a dense oxide yields a coarser powder. The oxide is reduced in an electrically heated quartz tube in an atmosphere of hydrogen. About 9 cu.ft. per minute of hydrogen is passed over each charge of 2 kg. The metallic tungsten powder is compressed into an ingot at a pressure of 50 tons per sq.in. The bar is then placed in a sintering furnace and heated by electric resistance almost to its melting point in an atmosphere of hydrogen. The sintering operation causes the crystallization of the metal. The bars are then heated and swaged or hammered at a temperature of about 1,500 deg. C., during which process the crystals become elongated. Finally, the swaged rods may be drawn into wire.

An interesting point was brought out by Dr. Balke's mention of the function of thoria in tungsten for lamp filaments. The thoria fuses, forming minute globules between the tungsten grains, thus retarding their growth. When the tungsten is drawn into wire, the thoria globules are drawn into little rods which prevent the crystallization and breaking of the filament.[2]

[1]See Jones, CHEM. & MET. ENG., vol. 22, p. 15 (Jan. 7, 1920).

[2]See Jeffries and Archer, CHEM. & MET. ENG., vol. 26, p. 406 (March 1, 1922.)

Dr. Balke stated that ten times as much pure tungsten is used for contact points for electrical equipment as for lamp filaments. He showed a large number of slides including photographs of the plant and apparatus and photomicrographs of the grain structure of numerous samples.

The freakish properties of vanadium, the history of its development and the modern process of extracting it from its ores were described by B. D. Saklatwalla. The element remained a laboratory curiosity for over a hundred years because no commercial deposits had been found. Studies of its effect in steel in 1900 may be said to mark the beginning of its commercial importance. Several processes of extracting the metal from its ores were described, the roasting and dry smelting process and the aluminum thermic reduction. The ordinary smelting processes are inefficient, because the oxides of vanadium are extremely refractory and combine with the flux and are lost. The Goldschmidt process overcomes this difficulty as it accomplishes instantaneous reduction by intense local heating. It is necessary however, to fix a very definite balance of ingredients in order to form the proper slag and to liberate the right amount of heat. The electric furnace method which is now being used duplicates this effect. The charge is fed continuously into the small space between the electrodes. A very high current density is used and the result is instantaneous reduction by the intense local heat.

Short Courses in Practical Paper Making Offered This Summer by University of Maine

During the period of six weeks beginning June 26 the chemistry department of the University of Maine will again conduct a summer school course in pulp and paper chemistry and technology. The University of Maine was the first institution to offer such a course in America and now has over ten years' experience in determining the nature of the courses offered and the content of each. In Maine today there is more capital invested in pulp and paper mills than in any other industry, and this fact alone means ever increasing co-operation between the pulp and paper courses of the university and the mills. Within a short distance of Orono are to be found pulp and paper mills of all kinds, soda, sulphite, sulphate and mechanical pulp mills, newsprint, bag, wrapping, tissue, novelty and writing paper mills.

Among the courses offered are the following: Paper testing and analysis; pulp manufacture, soda and sulphite processes; pulp bleaching and general, organic and physical chemistry.

The university library with its large collection of foreign and domestic pulp and paper journals, books and theses will be open daily. The paper and chemical work will be carried on in Aubert Hall under the same conditions as apply during the regular session.

Paint Works on Antimony Field in Australia

A new company has acquired the interests of the antimony and gold mines near Heathcote, Victoria, and intends to use the antimony sulphides for the manufacture of a metallic, non-poisonous paint. New works will be erected at a cost of £20,000, states the *Industrial Australian*, for the manufacture of paint and the production of refined antimony. Hitherto the antimony has been shipped to Yorkshire for treatment. The output is about 300 tons a month. The lodes have been proved to carry good values to a depth of over 900 ft.

Water Pollution Resolution Passes House

The Appleby resolution on pollution of navigable waters has been passed by the House. The resolution requests the President to call a conference of maritime nations with a view of adopting means to prevent the pollution of navigable waters by oil-burning and oil-carrying vessels. Representative Stafford, of Wisconsin, sought to have the resolution apply to the Great Lakes, but it was decided that this matter should be considered in a separate resolution.

Pan-Pacific Conference to Foster International Relations

The fourth conference called by the Pan-Pacific Union, of which Wallace R. Farrington, Governor of Hawaii, is president, will meet in Honolulu, Oct. 25, 1922. This is the fourth in the series of conferences which the Pan-Pacific Union is calling. The first was a conference of scientists from about the Pacific; the second, of educators; and the third, of journalists. The most valuable result coming from these gatherings of the leaders of the Pacific is the forming of interracial friendships—friendships which may have a vital influence in developing and preserving cordial relations among the nations themselves.

The conference will cover a period of 2 weeks, one of which will be devoted to sightseeing and entertainment features through Hawaii and Hilo. The business sessions will include discussions on communication, transportation, development of natural resources, finance and investments and international relations in the Pan-Pacific area. One day will be devoted to a discussion of significant Pan-Pacific commercial problems, one speaker from each country represented having been chosen to present the problems of his own country.

Bureau of Chemistry Book on Dust Explosions

"Dust Explosions," a book containing the results of 7 years of investigation by the United States Department of Agriculture, is soon to be issued by the National Fire Protection Association, Boston, Mass., in the interest of reducing fire and explosion losses. The book was prepared by David J. Price and Harold H. Brown of the Bureau of Chemistry of the department, and is expected to be a welcome addition to the meager literature on a subject that has been found of great economic importance to divers industries.

Chapters are devoted to nature and theory of dust explosions, industries producing dust and their extent, elimination of sources of ignition, prevention of explosions by control of explosive mixtures, phenomena of explosions, dust collection and removal, static electricity, explosions in grain-threshing machines, plant construction, cotton gin fires, coal dust explosions, and review of explosions.

Cotton Manufacturers' Association Indorses Dye Embargo

Continuance of the "qualified embargo on foreign dyes" was indorsed and approved by the American Cotton Manufacturers' Association in a resolution adopted at its twenty-sixth annual convention held in Washington. The resolution recommends to Congress passage of the provisions of the regular tariff bill providing for protection of the American dye and organic chemical industry.

Without protection, the resolution said, the "American dye industry would be crushed out and destroyed by the disastrous competition that would ensue." It is pointed out that all possibility of establishing an independent American dye industry will be lost for all time to come if the present development is destroyed.

Personal

FRANK W. DAVIS, who has been a metallurgist for a large part of the past 9 years with the Alan Wood Iron & Steel Co., is to be ferrous metallurgist of the Bureau of Mines. Mr. Davis will begin work on July 1 with headquarters at the Minneapolis station of the bureau. Under the direction of D. A. Lyon, chief metallurgist, he will be immediately responsible for co-ordination of the ferrous metallurgy research of the bureau.

T. H. EDWARDS, superintendent of the steel department at the Benwood, W. Va., plant of the Wheeling Steel & Iron Co., has resigned, following a service of 50 years in the industry. He will take up a residence at Denver, Colo.

DR. COLIN G. FINK has been appointed lecturer in electrochemistry and will have charge of that division of the department of chemical engineering, Columbia University, beginning July 1. He will continue his services as secretary of the American Electrochemical Society, office facilities having been arranged at Columbia for this.

F. S. HARVEY, engineer for the American Sugar Refining Co., gave an interesting address before a recent meeting of the Engineers' Club, Baltimore, Md., on the subject of the new local refinery of the company.

HARLAND M. JOSEPH, Midway, Del., has been appointed manager of the Lewes Fertilizer Co., Lewes, Del., succeeding William C. Lofland, deceased.

J. A. LECLERC has resigned from his position as chief chemist of the Miner-Hillard Milling Co., Williamsport, Pa. He is continuing his work on the problems of export of corn products, to which subject he has devoted himself for the past several months, largely working under the Bureau of Foreign and Domestic Commerce, for which he made a trip to Europe recently. Further effort in this field will be directed toward co-ordination among those who are interested in export of degerminated corn products, for which large foreign markets are expected.

PAUL LEONI, president of the Iron & Ore Corporation, 11 Broadway, New York, recently sailed for Europe on a business trip.

DORSEY A. LYON, chief metallurgist of the Bureau of Mines, had conferred upon him the degree of Doctor of Science by the University of Utah, in recognition of his services in developing metal research in this country.

WILLIAM J. MERTEN, metallurgical engineer of the Westinghouse Electric & Manufacturing Co., has been elected vice-chairman of the Pittsburgh chapter of the American Society for Steel Treating.

T. A. MITCHELL, consulting chemical engineer of Rogers, Brown & Co. of New York, returned May 22 from a trip to England, France and Belgium.

DR. CHARLES L. PARSONS, secretary of the American Chemical Society, sailed from New York June 13 to attend the conference of the International Union of Pure and Applied Chemistry, which will be held at Lyons, France, June 27 to July 2. Dr. Parsons also will attend the meeting at Marseilles of the society of French industrial chemists. He will address that gathering on "The Application of Chemical Research in Industry in America." Dr. Parsons is vice-president for America of the International Union of Pure and Applied Chemistry. Other delegates to the Lyons conference are: E. W. Washburn, H. S. Washington, Edward Bartow, Edward S. Chapin and R. B. Moore. Dr. Atherton Seidell, of the U. S. Public Health Service, also will attend the Lyons conference.

DAVID J. PRICE, chief of the dust explosions investigations of the Bureau of Chemistry, spoke before the Millers' National Federation convention in Kansas City on June 1. His address, entitled "Progress Made by Flour Milling Industry in Dust Explosion Prevention," related not only to the problems of prevention of explosions in cereal industries, but also to the general problem of preventing the hazards attendant upon the presence of industrial dusts. Special mention was made of several recent explosions where sulphur powder used in making lime sulphur insecticide had caused disastrous explosions.

Obituary

MICHAEL E. CLAFFEY, superintendent of the Monroe-Taylor Chemical Co., died at his home, 14 Stephens Court, Brooklyn, N. Y., May 27, aged 85 years.

H. T. OXNARD, for the past 10 years vice-president of the American Beet Sugar Co. and prior to that time president of the company, died at the University Club, New York, June 8, of heart disease. He was 62 years of age and resided at Upperville, Va.

Market Conditions

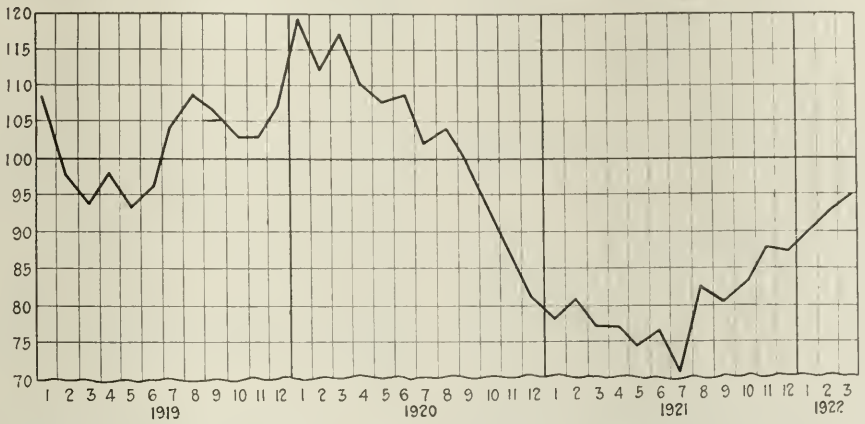
IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

The Increasing Volume of Manufacture

Some time ago the Harvard Economic Service constructed an adjusted volume index to follow the trend of production in the United States. In this index an attempt was made to eliminate both long-time and seasonal variations. In other words, the Committee on Economy Research sought to evaluate (1) the seasonal influences to which practically every industry is subject and (2) the long-time movement resulting from increasing population and industrial development.

As is evident from the accompanying chart, this index number is gradually approaching its normal value of 100, having risen from a low of 75 last July. In commenting on this improvement in the index in the weekly letter of May 27, the Harvard service makes the following significant statement: "The steady upward movement of production during the intervening months (July, 1921, to June, 1922) has afforded one of the most solid bases for optimism, since this increase in output has been in response to a definite increase of demand. This stimulus is more and more manifest."



THE HARVARD ECONOMIC SERVICE ADJUSTED INDEX OF THE VOLUME OF MANUFACTURE
(Normal = 100)

It is unfortunate that so few data are available on the volume of production in the chemical and allied industries. Current figures for a limited number of these commodities are normally compiled by certain governmental agencies and by the trade associations within these industries. On the whole, however, chemical production statistics are practically non-existent. The May number of the *Survey of Current Business* for the first time includes data on the monthly output of two important wood chemicals—acetate of lime and methanol, or wood alcohol. These figures show a very interesting trend, but it would of course be hazardous to intimate that they are indicative of production in all lines of chemical manufacture. The percentage comparisons with the preceding year are most striking. During the first quarter of 1922 there was produced 27,570,000 lb. of calcium acetate—a 50.6 per cent increase over production in the same period of 1921. The output of methanol during this period was 1,473,652 gal. as compared with 1,262,760 gal. in Jan.-Feb.-March, 1921. This is an increase of 16.7 per cent. In March, 1922, the production of methanol was 587,928 gal., while in the corresponding month in the preceding year it was but 403,838 gal.

Other production and consumption statistics of interest to the chemical industries are shown in Table I. These are from the "Trend of Business Movements" section of the Department of Commerce *Survey of Current Business*. It is to be hoped that the organization of a chemical commodity division in the Bureau of Foreign and Domestic Commerce will be followed by an intensive effort to compile and promptly present current production statistics on such basic chemical commodities as sulphuric and the other mineral acids, caustic soda and the alkalis, and ammonium sulphate and other fertilizer materials.

TABLE I—THE TREND OF PRODUCTION IN CERTAIN OF THE CHEMICAL AND RELATED INDUSTRIES

Production of—	Feb., 1922	Mar., 1922	First 3 Months of 1921	First 3 Months of 1922	Percentage Increase or Decrease In 1922
Acetate of lime, thous. of lb.	7,942	11,134	18,309	27,570	+50.6
Alcohol (wood), gal.	433,024	587,928	1,262,760	1,473,652	+16.7
Cement, thous. of bbl.	4,278	6,685	15,240	15,254	+0.1
Coke, byproduct, thous. of short tons	1,795	2,137	5,938	5,835	—1.7
Coke, beehive, thous. of short tons	549	732	2,577	1,777	—31.0
Cottonseed oil, thous. of lb.	91,321	72,237	483,222	264,264	—45.3
Leather, sole, thous. of sides	1,466	1,473	3,720	4,593	+23.5
Leather, finished upper, thous. of sq.ft.	70,296	77,510	118,827	222,369	+87.1
Linseed oil*, thous. of lb.	6,647	7,232	20,631	20,336	—1.4
Metals:					
Pig iron, thous. of long tons	1,630	2,035	5,949	5,303	—10.9
Steel ingots, thous. of long tons	2,072	2,816	6,560	6,781	+3.4
Copper, thous. of lb.	37,416	61,867	251,564	125,131	—50.3
Zinc, thous. of lb.	45,026	53,064	118,852	145,502	+22.4
Paper and pulp:					
Wood pulp, chemical, sh. tons	144,568	170,995	379,749	473,309	+24.6

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week 157.93
Last week 158.12

June, 1917	222	June, 1918	272
June, 1920	274	June, 1921	147
April, 1918 (high)	286	April, 1921 (low)	140

This week's index number reflects the slightly lower prices for barium chloride and linseed oil. Higher prices noted in the case of benzene and copper sulphate were insufficient to offset the decline. Since May 24 this index number has fallen almost 3 points.

Davison Chemical Co. Reports Six-Million Dollar Surplus in 1921

The annual report of the Davison Chemical Co. and its subsidiaries, the Davison Sulphur & Phosphate Co. and the Silica Gel Corporation, is notable in that it is one of the few fertilizer manufacturing companies to have met the deflation of 1921 without seriously impairing its surplus. The profit and loss surplus at the end of 1921 stood at $1,804,336, to which has been added $4,425,709 as capital surplus value of ore blocked out, giving a total surplus of $6,230,045. This compares with $6,641,984 in 1920 and $6,273,926 in 1919.

According to an analysis of the consolidated balance sheet which has been made by the *Wall Street Journal*, the company retired $604,000 of Davison Sulphur & Phosphate bonds in 1921 at a cost of $579,451. Prior to March 1, 1922, bonds of $1,122,000 par value were converted into 18,700 shares of stock in the Davison Chemical Co., so that the only funded debt now is $2,000,000 of 8 per cent gold debentures.

Investment in the Silica Gel Corporation (200,000 shares) is carried at $24,795, while $408,479 is due from the corporation in accounts receivable. Presumably this is the money advanced for experimental and research work and in constructing the experimental plant for oil refining. The total accounts receivable are $860,262, compared with $540,928 last year. Cash and inventories show little change from the previous report. Current liabilities are $1,153,691, including $703,331 notes and $331,156 accounts, as against $526,758 in notes and accounts last year. Reserves for depreciation amount to $804,345, against $799,919. Working capital is $1,152,150, as against $1,957,363 last year.

The New York Market

NEW YORK, June 12, 1922.

Trading so far during the month of June has been without significant developments. The chemical market has been colorless and except for the merest routine, business has been unusually quiet.

Consumers, it would appear, are showing no inclination to lay in large stocks and are buying in small lots—often in the spot and resale markets. Manufacturers, on the other hand, believe that the bottom of the market has been reached and therefore are inclined to wait for the enactment of pending tariff legislation in the hope that it will bolster up prices.

From the long-time viewpoint the dye people have reason to be encouraged, first by the higher scale of duties recently approved in the Senate and second by the resumption of activity on an increasing scale in the textile centers. Unfortunately, however, neither of these factors is having immediate effect and with the exception of higher prices asked by the producers for a few crudes, the coal-tar products market remains stagnant.

INDUSTRIAL CHEMICALS

Alums—The alum group is being quoted at somewhat lower prices notwithstanding reports of production difficulties. Imported potash alum is quoted at $3.75@$4 per 100 lb., but in some quarters prices as low as $3.10 were heard. Chrome alum is being handled at 5¼@6c., as compared with a price of 7c. a few weeks ago. Ammonia alum is unchanged at 3½@3¾c. for sizable orders.

Ammonium Sulphate—The market for this and most other fertilizer materials has been without change, although announcement of next season's price is expected soon. It is rumored that on ammonium sulphate the new price will be in the neighborhood of $3 per 100 lb. At present trading is at $3.25@$3.40 per 100 lb. in double bags f.a.s. New York.

Arsenic—Importers report a fair inquiry for Japanese white arsenic. In carlots this is quoted at 6¾@7c. per lb.

Barium Chloride—Trading in this article has eased up a bit of late and the tendency is toward lower prices. Imported material for June arrival is being offered at $88@$90. Spot supplies are held at $97@$100, the latter being the price asked by the domestic producers.

Caustic Potash — The market remains unchanged at $5.75@$6 for sizable orders and shipment material is held at slightly lower prices.

Caustic Soda—Inquiries from abroad are being received in fair volume, according to the exporters, and the 76 per cent in drums is quoted at $3.85 f.a.s. The domestic prices are $3.75@$4 for contracts, carlots, ex-works. The ground and flake caustic can be bought in drums at the producer's plant for 3¾@3⅞c. per lb.

Copper Sulphate—The scarcity of blue vitriol is as yet unrelieved and spot material is difficult to purchase under 6c. per lb.

Oxalic Acid—Although business in oxalic is slow, the recent high prices still prevail, principally because this material is scarce in the New York market.

Prussiate of Potash—Red prussiate of potash is back in the market again this week, but supplies are comparatively small. The yellow salt is in somewhat better supply, but prices are showing an upward tendency. Red prussiate is quoted at 80@85c. and the yellow at 32@33c.

Prussiate of Soda—The market is at a standstill and goods on hand are moving at 21½@22c., with lower prices offered for future delivery.

Shellac—Slight advances in price have been applied all along the line due both to the strengthening sterling exchange and recent information that foreign supplies are not too abundant. T. N. is quoted for shipment, June arrival, at 78c., but the price in the spot market has been 80@82c. Orange superfine is selling for 84@86c. per lb., and the A. C. garnet at 66@68c.

Sodium Nitrate—Crude saltpeter is somewhat lower in the spot market, with $2.50@$2.75 covering the general range of quotations.

Sodium Silicate—New contract prices for the 40 deg. material are said to be 75c. per 100 lb. in tank cars, f.o.b. works, 80c. in drums for carlots and less than carlots at $1.05.

Tartaric Acid—The market for tartaric acid is somewhat firmer and during the week advances of ½@1c. were reported. Imported crystals now sell for 28½@29c. and the powdered at 29½@30c.

VEGETABLE OILS

Cottonseed Oil—There have been few developments in the local oil market during the past week. Cottonseed oil exports have fallen to practically nothing. Crude oil was not offered in any quantity and what transactions took place were at 10c. per lb., buyers' tanks, f.o.b. mills.

Linseed Oil—The market for linseed oil has been comparatively quiet, with a tendency toward lower prices. Domestic crushers maintained 82@84c. per gal., but quotations as low as 80c. were heard during the week. The imported oil for June shipment was quoted at 78@80c.

The St. Louis Market

ST. LOUIS, June 8, 1922.

The St. Louis market for industrial chemicals was somewhat stagnant last week, due in all probability to the holiday intervening. There is more activity this week, however, and prices in general are very firm. In fact there is more stability to the market today than there has been for many months past. Domestic manufacturers do not feel the effects of imported material as severely as they did some time ago, although at times the foreign material still upsets the market temporarily. The volume of business transacted during the month of May was very appreciable with favorable indications for continuance.

ALKALIS

Contrary to our prediction in the May 23 report, *caustic soda* did not advance, but has remained the same or been shaded slightly in one or two instances. The *soda ash* mar-

ket has been very quiet recently, but prices have held up to former levels. *Sodium bicarbonate* is moving freely and maintaining a steady price. *Sal soda* is selling in good volume, but competition has caused some decline in recent prices.

General and Special Chemicals

The *sulphuric, nitric and muriatic acid* group is moving very well and prices are somewhat firmer today. *Citric acid* remains in good demand, with limited stocks in some localities. The advance which was expected some time ago has not as yet materialized. There has been very good inquiry for *oxalic acid*, but we do not believe that the actual buying has been in proportion with the volume of inquiry. *White arsenic, powdered*, today is quoted at 7½c. per lb. f.o.b. St. Louis, with a strong market. *Carbon bisulphide* is moving quite freely and orders of large volume are being placed. Prices are firm. *Epsom salts* is in fair demand and being quoted at $2.50@$2.60 per 100 lb., f.o.b. St. Louis. *Glycerine* apparently has reached rock bottom. We had predicted a decline, but so far it has failed to materialize, and since quite a few contracts are renewed about this time a decline now is hardly to be expected. The demand for *potassium ferricyanide* is far in excess of available stocks. *Sodium cyanide* is in good demand, and with the imported material gradually disappearing, the demand for domestic goods is much better. *Sulphur* has not changed in price and the volume of business on this item continues heavy. *Zinc sulphate, technical*, is moving freely with a strong market at 3c. per pound, f.o.b. St. Louis.

Vegetable Oils and Naval Stores

Linseed oil has suffered a slight decline since our last report and is now quoted at $1.01, basis raw oil. *Turpentine* continues around $1, with the usual daily up and down fluctuation. *Castor oil* shows no tendency to weaken and the price of 12¾c. in 200-gal. lots seems to be absolutely rock bottom.

Paint Materials

The paint grinders in this locality are kept very busy and the result is plainly evident in their purchases. So far no dealer has developed sufficient courage to advance prices, so we have no changes to report.

The Iron and Steel Market

PITTSBURGH, June 9, 1922.

The monthly report of the American Iron and Steel Institute, giving the steel ingot production of the thirty steel companies that make monthly returns, indicates that the industry as a whole produced steel ingots in May at the rate of about 38,250,000 tons per annum, against a rate of about 36,600,000 tons in April. The rate at the end of March, when the coal strike began, was about 35,000,000 tons. The rate at present is probably a trifle above the average rate during May. Thus there has been an increase of something like 10 per cent in steel production since the coal strike started, following an increase of about 75 per cent in the 3 months preceding.

The Coal Strike and Its Effects on Steel Production

The steel market is still a strong one and this fact, taken in connection with the increased production of steel in the first 2 months of the coal strike, makes it difficult to follow the theory that the strength of the steel market in the past few months has been due chiefly to the coal strike because the strike made buyers of steel anxious to pile up stocks against a possible interruption in shipments. Had buyers been actuated chiefly by such a motive, they would by this time be in such position as to be forced to begin liquidating the stocks thus accumulated.

That the coal strike has had a favorable influence upon the steel market in the matter of tonnage demand and in the prices obtainable for steel cannot be denied, but it cannot be maintained that the coal strike has been the chief factor.

On the other hand, it cannot be denied that the movement begun in the steel market will not last forever. The longest movement, outside of the war period, lasted 3 years, from late in 1904 to late in 1907. The shortest movement lasted more than a year, from the time buying became fairly active to the time mills had to begin curtailing production on account of orders running short. The present is a regular movement, not a little burst of activity due to the incident of the coal strike. Those who have the least respect for the movement expect it to run well through autumn.

On April 1, when the coal strike started, steel production was at about two-thirds of capacity. It looked then as if the idle third was taken out by the coal strike, the analysis on this basis being that the steel market was as strong with a two-thirds operation as it used to be with a full operation. Now the operation is nearly if not quite three-fourths and it would be quite rash to assume that the ending of the coal strike would make the other one-fourth effective. Labor shortages began appearing at a few points several weeks ago, and transportation shortage would probably prevent a 100 per cent operation of the steel industry, apart from other considerations. There is nothing weird about such suppositions. It is true that before the war the steel industry was always able to operate at its capacity when it had the necessary orders, except during the winter of 1902-3, when the first transportation breakdown in the history of American railroading occurred, but the situation today seems to be that the steel industry, with an actual capacity in ingots of 50,000,000 or 55,000,000 tons, is too big for the rest of the country.

Steel Prices

Steel prices are very firm all along the line, and in several products the minimum prices are made only by the Steel Corporation subsidiaries and then only to regular customers for delivery at mill convenience, other inquiries being turned down, whereupon the business goes to independents at higher prices. Along this line bars, shapes and plates are quotable at 1.60@1.80c., depending on the buyer, the tonnage, the specifications and the time of delivery.

A feature of the market situation is that steel is steel. The bottle neck is ingots. It is a detail what the steel is finished into, there being plenty of finishing capacity. Bars, shapes and plates are therefore on a level with each other. Likewise billets, small billets and sheet bars are all equally quotable at $35 Pittsburgh or Youngstown. Sales of sheet bars at $35 are now being made for July delivery.

Plates, Sheets and Steel Products

The American Sheet & Tin Plate Co. has opened its order books for tin plate for second half delivery to manufacturing consumers and third quarter to jobbers, these being the usual periods. The price remains at $4.75. Some of the independents had been talking of an advance to $5, but $4.75 is considered high enough. In sheets the company opened its books for July only, this being an innovation. Likewise the prices are unchanged, at 2.40c. for blue annealed, 3.15c. for black, 4.15c. for galvanized and 4.50c. for automobile sheets. Most independents, who had sold more or less for July at old prices, are now asking $2 a ton more for blue annealed, $3 more for black and galvanized, and $5 more for automobile sheets.

Hoops, bands and hot-rolled strips are now commonly quoted at 2.40c., but the old price of 2.25c. can perhaps be done with the Steel Corporation by some regular customers. Cold-rolled strips have been advanced by independents to 4c., the American Steel & Wire Co. remaining at 3.75c. The wire company remains at $2.40 on nails and independents have been forced to recede from their $2.50 price, made about the middle of April, in the case of the most attractive orders.

The steel industry seems fortified to continue its present rate of production almost indefinitely despite the coal strike, which shows no material change.

The local pig iron market remains stagnant, the quotable level, largely nominal, remaining at $25 valley for bessemer and basic and $24 for foundry.

Tin oxide	lb.	..... –	.35 – .37
Zinc carbonate	lb.	.14 – .14½	.14¾ – .15½
Zinc chloride, gran	lb.	.05¼ – .05½	.05¾ – .06½
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08¼ – .08½
Zinc sulphate	100 lb.	2 75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.14 — .16
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P	lb.	1.25 — 1 30
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.80 — .85
Benzoic acid, U.S.P	lb.	.60 — .65
Benzoate of soda, U.S.P	lb.	.50 — .55
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.50 — .55
Beta-naphthol, tech	lb.	.23 — .26
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.53 — .55
Cresylic acid, 95-97%, dark, in drums	gal.	.48 — .50
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.65 — .70
Dimethylaniline	lb.	.36 — .38
Dinitrobenzene	lb.	.22 — .25
Dinitroclorbenzene	lb.	.22 — .24
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .65
H-acid	lb.	.80 — .95
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.09 — .11
Monoethylaniline	lb.	1.05 — 1.25
Naphthalene crushed, in bbls	lb.	.06 — .06¾
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.08 — .08
Naphthionate of soda	lb.	.58 — .65
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17
N-W acid	lb.	1.15 — 1.30
Ortho-amidophenol	lb.	.40 — 2.50
Ortho-dichlor-benzene	lb.	2.15 — .20
Ortho-nitro-phenol	lb.	.70 — .75

Ortho-nitro-toluene	lb.	$0.10 —	$0.13
Ortho-toluidine	lb.	.14 —	.18
Para-amidophenol, base	lb.	1.25 —	1.30
Para-amidophenol, HCl	lb.	1.30 —	1.35
Para-dichlorbenzene	lb.	.17 —	20
Paranitroaniline	lb.	.75 —	.77
Para-nitrotoluene	lb.	.55 —	.65
Para-phenylenediamine	lb.	1.55 —	1.60
Para-toluidine	lb.	.90 —	1.00
Phthalic anhydride	lb.	.35 —	.38
Phenol, U. S. P., drums	lb.	.14 —	15
Pyridine	gal.	1.75 —	2.75
Resorcinol, technical	lb.	1.30 —	1.35
Resorcinol, pure	lb.	1.75 —	1.80
R-salt	lb.	.60 —	70
Salicylic acid, tech., in bbls	lb.	.25 —	.25½
Salicylic acid, U. S. P.	lb.	.26 —	.26½
Solvent naphtha, water-white, in drums, 100 gal	gal.	.27 —	.32
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.14 —	.18
Sulphanilic acid, crude	lb.	.24 —	.26
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	28
Toluene, in drums	gal.	.30 —	35
Xylidines, drums, 100 gal	lb.	.40 —	45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	.33 —	.35
Xylene, commercial, in tank cars	gal.	.30 —	....

Waxes

Prices based on original packages in large quantities f.o.b. N.Y.

Bayberry Wax	lb.	$0.20 —	$0.21
Beeswax, refined, dark	lb.	.26 —	.28

Silica, building sand, f.o.b. Pa.	per ton	2.00	— 2.75
Soapstone	ton	12.00	— 15.00
Talc, 200 mesh, f.o.b. Vermont	ton	7.00	— 12.00
Talc, 200 mesh, f.o.b. Georgia	ton	7.50	— 12.00
Talc, 200 mesh, f.o.b. Los Angeles	ton	16.00	— 20.00

Ferro-Alloys

Ferrocerium, Ferrochrome, Ferromanganese, Ferromolybdenum, Ferrosilicon, Ferrotitanium, Ferrotungsten, Ferrouranium, and Ferrovanadium are unchanged from the prices published June 7.

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and larger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named:

	New York	Chicago
Structural shapes	$2.58	$2.48
Soft steel bars	2.48	2.38
Soft steel bar shapes	2.48	2.38
Soft steel bands	2.98	2.98
Plates, ¼ to 1 in. thick	2.58	2.48

Industrial

Financial, Construction and Manufacturers' News

Industrial Developments

CERAMIC—The Hazleton Brick Co., Hazleton, Pa., has adopted a capacity schedule at its plant, and is said to have orders on hand to insure continuous production throughout the summer.

The Star Porcelain Co., Trenton, N. J., manufacturer of electrical porcelain products, is operating under regular production with full working force. The plant is now running heavy on specialties for radio service.

The Perth Amboy Tile Works, Perth Amboy, N. J., is operating at full capacity with regular working force. The company has orders on hand for a number of months to come. Extensions are being made for increased capacity.

RUBBER—The Electric Hose & Rubber Co., Wilmington, Del., manufacturer of heavy hose and other rubber goods, is running under day and night shifts. Orders are well in excess of production.

The Amazon Rubber Co., Akron, O., is planning to double its present capacity of 100 tires a day before the close of June. Additions are being made to the working force.

The Firestone Tire & Rubber Co., Akron, O., is maintaining production at maximum capacity, and has advanced the wages of all employees in the factory from 9 to 12 per cent. The wages of office workers have been increased 10 per cent.

The rubber industry at Akron, O., is now employing close to 50,000 workers, as compared with about 35,000 employees a year ago, and 80,000 in February, 1920, the peak period.

The Republic Rubber Corp., Youngstown, O., is operating on a two-shift basis at its local plant, giving employment to about 1,000 men. The belting and inner tube branches have recently advanced their schedules to a three-shift basis.

Offers are being made for the plant of the Batavia Rubber Co., Batavia, N. Y., which recently went into the hands of a receiver, and it is expected that operations will be resumed at an early date.

The Studebaker-Wulff Rubber Co., Marion, O., is arranging for a further increase in production from 100 casings and tubes each per day, to 150 each daily.

IRON AND STEEL—The Sloss-Sheffield Steel & Iron Co. has blown in its stack at Florence, Ala., after a suspension of a number of months, making a total of five blast furnaces of the company now in operation.

The Reading Iron Co., Reading, Pa., is increasing operations at its North 9th St. plant, and has placed the universal mill in service, following a suspension since last September. The unit will give employment to about 100 additional men.

The Brier Hill Steel Co., Youngstown, O., has blown in another blast furnace at its plant, following an indle period of a number of months. All stacks at this plant are now in service.

The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., is completing repairs on three furnaces at its plant and expects to place two of the units in operation at an early date for the production of foundry iron.

The Nagle Steel Co. is increasing operations at its Pottstown Pa., plant. The Glasgow Iron Co., in this same section, is running at its mill and has twelve of its fourteen puddling furnaces in service.

Steel manufacture in the Mahoning Valley section of Ohio and in the Cleveland (Ohio) district is now about 75 per cent of capacity, being held at this basis on account of the coal strike and consequent fuel shortage at certain plants.

The Central Steel Co., Massillon, O., is operating at close to 100 per cent at its different plants, including the National Pressed Steel Co. and the Massillon Rolling Mill Co., recently merged with the Central company. A wage advance of 10 per cent has been made at the mills, effective June 1, affecting about 2,000 employees.

The Robesonia Iron Co., Ltd., Robesonia, Pa., is arranging to blow in its blast furnace on low-phosphorus iron about the middle of June.

LEATHER—The Benz Kid Co., Lynn, Mass., is increasing production at its local tannery to handle heavy incoming orders.

The Sparrowbush Tanning Co., Sparrowbush, near Port Jervis, N. Y., is developing an increased output at its plant, comprising the former Hammond tannery, recently acquired. It has a capacity of 1,200 sides a day and will soon be running at maximum.

Six of the largest of the twenty-two tanneries at Chicago, Ill., are curtailing production, due, it is stated, to lack of orders. The total decrease in output approximates 40,000 sides a week.

OIL—The Chickasaw Refining Co. is arranging for the early resumption of operations at its Ardmore, Okla., oil refinery, following a shutdown for the last six months.

The Dale Refining Co. has completed the remodeling of the old oil refinery at Humble, Tex., and is now running on a basis of about 350 bbl. of oil daily.

MISCELLANEOUS—The Owens Bottle Co., Pittsburgh, Pa., is making repairs at its Clarksburg, W. Va., plant, and will place the works in operation at an early date.

The Sherwin-Williams Co., Cleveland, O., is running all of its paint and varnish plants at normal capacity. Other paint manufacturers in this district have also adopted full-time operating schedules, with regular working forces.

The United States Cast Iron Pipe & Foundry Co., East Burlington, N. J., is now operating at about 70 per cent of capacity at its different plants throughout the country, as compared with a 55 per cent production basis two months ago.

The Spanish River Pulp & Paper Mills, Ltd., Montreal, Que., has developed a maximum output of 307 tons a day at its Espanola plant, or about 50 tons greater than originally planned.

Construction and Operation

Arizona

MORENCI—The Stargo Mines, Inc., is completing plans for the construction of a new cyanide plant, with initial capacity of about 75 tons a day, estimated to cost close to $80,000. The General Engineering Co., Salt Lake City, Utah, is engineer.

California

REDLANDS—J. H. Strait & Co. have plans and specifications under way for the construction of a new fruit dehydrating plant in the vicinity of their present work.

Delaware

WILMINGTON—The Wilmington Sugar Refining Co., Christiana Ave. and B St., has foundation work under way for the main building at its new local sugar mill, comprising a 5-story structure, 100x200 ft., estimated to cost about $800,000, including equipment. W. J. Wayte, Inc., 125 East 46th St., New York, N. Y., is engineer.

WILMINGTON—The Charles Warner Co., Wilmington, has acquired the plants and properties of the American Lime & Stone Co., Tyrone, Hollidaysburg and Bellefonte, Pa., comprising chemical limestone land totaling about 7 miles long, with fluxing stone sites and other mineral properties. The holdings are valued at $3,000,000. The new owner plans extensive operations at the mills, primarily for lime production, and is said to be arranging for a number of extensions and improvements. The company has disposed of a bond issue of $1,100,000, the proceeds to be used in connection with the project.

Florida

GAINESVILLE—The Standard Fertilizer Co. is planning for the rebuilding of the portion of its plant destroyed by fire, May 23, with loss estimated at about $30,000, including equipment.

Georgia

COLUMBUS—The Armour Fertilizer Co., 209 West Jackson Blvd., Chicago, Ill., will commence the immediate construction of a new local plant to replace the portion of its works recently destroyed by fire.

PORT WENTWORTH—The Atlantic Paper & Pulp Co. is planning for the rebuilding of the section of its works, recently destroyed by fire with loss approximating $50,000, located at Port Wentworth, a suburb of Savannah.

Indiana

INDIANA HARBOR—The Steel & Tube Co. of America, 111 West Washington St., Chicago, Ill., has authorized the immediate preparation of plans for the construction of two new mills at its local works, to be equipped for an annual capacity of about 100,000 tons. To carry out the details of the project a stock issue of $6,000,000 is planned. Herbert H. Springford is president.

Kentucky

ASHLAND—The Pittsburgh Brick & Tile Co. has been organized under state laws, to construct and operate a plant for the manufacture of brick, tile and other burned clay products. A tract of about 400 acres of land has recently been acquired at Summitt, and plans for the initial plant units are nearing completion. The company is headed by A. C. Bailey, W. L. Bybee and S. S. Willis, Ashland.

Louisiana

COVINGTON—A new company is being organized, it is said, to take over and operate the plant of the Covington Moss Works, Inc., soon to be offered at a public sale to satisfy creditors. The plant is equipped for the manufacture of artificial moss, and will be extended and improved by the new owner.

NEW ORLEANS—The Armour Fertilizer Works, 209 West Jackson Blvd., Chicago, Ill., has awarded a contract to Hugger Brothers, Montgomery, Ala., for the rebuilding of the portion of its plant at Shrewsbury, near New Orleans, destroyed by fire late in April with loss approximating about $250,000, including equipment. The new structures will cost close to this amount.

SWARTZ—The Huber Carbon Co. has completed plans for extensions in its local mill to double the present capacity, and will commence work at an early date. A new gasoline extraction plant will also be constructed.

NEW ORLEANS—The Richardson Co., Cincinnati, O., manufacturer of composition paper roofing and kindred products, has plans under way for the construction of an addition to the plant of the Century Roofing Co., New Orleans, an affiliated organization, to cost about $500,000, including equipment.

MONROE—The Constantin Refining Co., Monroe, is completing the construction of a new gasoline-absorption plant in Union County, Ark., and plans to place the mill in service at an early date. It will have an initial capacity in excess of 4,000 gal. a day, and this output will be increased in the future.

Maryland

BALTIMORE—The Patuxent Clay Products Co., 210 Equitable Trust Bldg., will call for bids before the end of the month for the construction of its proposed new plant on property recently acquired at Patuxent. It will be equipped for the manufacture of brick, tile and other burned clay products, and is estimated to cost close to $100,000 with machinery. I. P. Mills is head.

BALTIMORE—E. J. Callahan & Co., manufacturers of glass products, have leased property at 14-16 West Barre St., for a new local works.

Massachusetts

BOSTON—Fire May 30 destroyed a portion of the building of the Acme White Lead & Color Co., with loss estimated at about $13,000.

New Jersey

NEWARK—D. E. Evarts, 134 Gifford Ave., Jersey City, has acquired the plant of the Schofield Oil Co., Ave. R, Port Newark district, at a receiver's sale for a consideration of $160,500, and is organizing a company to operate the business. The plant consists of three main buildings, on site

aggregating about 5½ acres of land, and will be improved by the new owner.

GARWOOD—The Federal Foundry Co. has acquired the local plant of the Garwood Bronze & Iron Co., North Ave., for a new foundry. George H. Cross is president.

LAMBERTVILLE—The Jesperson Newsprint Corp. is planning for the early operation of its local plant, comprising the former mill of the Perseverance Paper Co., lately acquired, for the manufacture of newsprint from used stock by a special process. The equipment is being remodeled and the plant improved, and it is expected to give employment to a large working force. Henry Weeks is treasurer and general manager.

PERTH AMBOY—The Perth Amboy Oil & Terminal Co., recently organized, has acquired a site near the city for a new oil distributing plant, estimated to cost about $125,000, including equipment. The company is affiliated wth the Able Refining Co., Houston, Tex. Luke Mooney, Sewaren, N. J., is president; and A. L. Baker, 25 Broad St., New York, N. Y., treasurer.

New York

YONKERS—The Arlington Chemical Co., 100 Hamilton St., has authorized the preparation of plans for the erection of a new 4-story plant, in the vicinity of Herriott St., estimated to cost in excess of $50,000. Timmis & Chapman, 315 5th Ave., New York, are architects. John E. Andrus is president.

NIAGARA FALLS—The Defiance Paper Co., Walnut Ave., will soon commence the erection of an addition to its plant to cost about $200,000, including equipment. The extension will be equipped to give employment to about 100 men.

BINGHAMTON — The F. E. Harris Co., North Chenango St., manufacturer of flavoring extracts, etc., has broken ground for the erection of a 1-story addition, 175x175 ft., estimated to cost about $42,000, including equipment. The general contract has been let to B. L. Gabriel, Security Mutual Bldg.

LITTLE FALLS—The Barnet Leather Co., 81 Fulton St., New York, has excavations under way for the erection of a 3-story addition to its plant, estimated to cost about $100,000, including tanning and operating machinery.

LONG ISLAND CITY—The Nichols Copper Co., 25 Broad St., New York, is considering plans for the rebuilding of the portion of its plant on Newtown Creek, destroyed by fire May 27, with loss reported at close to $200,000, including equipment.

LOCKPORT—The A. W. Jack Corp., Mill St. and North Transit Road, manufacturer of asbestos mill board and kindred products, has awarded a contract to the J. W. Cowper Co., Fidelity Bldg., Buffalo, for the erection of its proposed new 1-story plant, 128x500 ft., estimated to cost close to $400,000, including machinery. George F. Hardy, 309 Broadway, New York, is engineer.

North Carolina

WAYNESVILLE—The American Mica Mining Corp. is planning for the establishment of a new mica mining and conversion plant. A list of machinery for installation is being arranged. Harry M. Hall is secretary.

Ohio

AKRON—The National Sulphur Co., Constable Hook, Bayonne, N. J., has construction well under way on a new plant at Bettes Corners, comprising a series of seven large buildings and a number of smaller structures. It is purposed to remove the Bayonne works to this location. The new plant will cost about $400,000, and is expected to be ready for service at an early date. It will give employment to about 350 men.

CLEVELAND—The Colonial Steel Co., Keystone Bldg., Pittsburgh, Pa., has plans under way for the erection of a new building on property recently purchased at 2121 St. Clair Ave., to be equipped as a heat-treating plant.

Oklahoma

HUGO—The local Chamber of Commerce is interested in a plan for the establishment of a local acid and dye plant, utilizing the bois d'arc wood materials from Choctaw County. A company will be organized, according to tentative arrangements, to operate the works.

TULSA—The Sinclair Oil & Gas Co. has arranged an appropriation of $1,000,000, for the construction of new gasoline extraction plants in the Mid-Continent field, and improvements in its present plants. H. B. Bernard, superintendent of gasoline plants, is in charge.

Pennsylvania

ROCHESTER—The American Borax Co., E. L. Dawes, president, care of the Standard Sanitary Mfg Co., Bessemer Bldg., Pittsburgh, has awarded a contract to the Austin Co., 16116 Euclid Ave., Cleveland, O., for the erection of a new addition to the plant building of National Glass Co., recently acquired. It will be 50x100 ft., and is estimated to cost close to $100,000. The existing buildings will be remodeled and improved to accommodate the new works.

LOCK HAVEN—The General Refractories Co., Oliver Bldg., Pittsburgh, is negotiating for the purchase of the plant of the Pennsylvania Fire Brick Co., Beech Creek, near Lock Haven, and upon acquisition, will merge the company with its organization. The plant will be continued in operation and improvements made. The company is also reported to be arranging for the purchase of the plants of the Hiram Swank's Sons Co., at Johnstown and vicinity.

LANCASTER — The Armstrong Cork Co., Liberty and Mary Sts., will soon break ground for the erection of a 1-story addition, 60x60 ft.

PHILADELPHIA—H. Swoboda & Son, Inc., 1027 North Bodine St., manufacturer of leather products, has awarded a contract to the John N. Gill Construction Co., 112 South 16th St., for the erection of a 1-story addition.

SINNAMAHONING—Fire May 26 destroyed a portion of the local powder works of the Grasselli Chemical Co. An official estimate of loss has not been made. The plant is operated in the name of the Grasselli Powder Co. Joseph S. Burton is president.

READING—A new 1-story foundry will be erected at the plant of the Reading Knob Works, about 30x50 ft. C. B. Mongel, 1122 Pennsylvania Ave., Wyomissing, Pa., is architect.

MONTROSE—The Binghamton Limestone Co., Binghamton, N. Y., has preliminary plans under way for the erection of a local plant, estimated to cost in excess of $50,000, including buildings and equipment. E. E. Kellogg, care of the Kellogg-Jones Co., O'Neil Bldg., Binghamton, is treasurer.

Tennessee

KNOXVILLE—The Kinney Chemical Co. will soon break ground for the erection of a new plant. F. L. Kinney is vice-president and general manager.

Texas

FORT WORTH—The Magnolia Petroleum Co. is reported to be planning for the rebuilding of the portion of its distributing plant, destroyed by fire May 28, with loss estimated at close to $300,000.

GRAND PRAIRIE—The Prairie Refining Co. is planning for the early operation of its new local oil refinery, now nearing completion. The plant will have an initial output of 300 bbl. per day, including lubricating oils, grease, asphalt, paints, etc., and at a later date will be increased. I. B. Walker is president.

Virginia

COVINGTON—The Town Council will construct a new mechanical filtration plant in connection with the installation of a waterworks system. C. P. Barnett, Covington, is consulting engineer.

LYNCHBURG — The Lynchburg Pigment Corp., P. O. Box 128, has leased the local plant of the National Pigment & Chemical Co. for the establishment of a works for the manufacture of ochre, talc and kindred specialties. Operations will be commenced at an early date. John A. Weinman is president.

West Virginia

KENNILWORTH—The Globe Brick Co. is reported to be planning for the rebuilding of the tunnel dyring department at its plant, recently destroyed by fire.

LUMBERPORT—The Mound City Glass Co., manufacturer of tumblers and other plain blown glass products, will commence the immediate erection of an addition to its plant to double, approximately, the present output. It will cost in excess of $40,000.

NITRO—The Carrier Chemical Co., recently organized, has plans under way for the establishment of a local plant for the manufacture of a line of finished chemical products. M. T. Davis, Jr., is president.

HUNTINGTON—The Bishop Sons Co., New Cumberland, W. Va., has plans under consideration for the establishment of a new branch plant for the manufacture of lamp chimneys and kindred products.

Wisconsin

NEENAH—The Valley Paper Mills, Wisconsin Ave., will take bids at once for the erection of their proposed new plant in the Blair Springs district, comprising a main 2- and 3-story mill, 80x160 ft., estimated to cost about $750,000, including machinery. Edward A. Wettengal, 578 Pierce Ave., Appleton, Wis., is architect and engineer. G. W. Burnside is secretary and general manager.

Canada

KINGSTON, ONT.—The Frontenac Floor & Wall Tile Co. has construction under way on an addition to its plant to double, approximately, the present capacity. Two new kilns will be built to be used primarily for wall tile production. The company has recently completed the installation of a new grinding mill for feldspar production. Everett Townsend is general manager.

MONTREAL, QUE.—The National Electric Products, Inc., recently consolidated with the Dominion Oxygen Co., Ltd., has plans under way for the erection of a number of commercial oxygen plants in different industrial centers in Canada. The enlarged company is closely allied to the National Carbon Co.

New Companies

THE FLANDILL PRODUCTS CORP., New York, N. Y., has been incorporated with a capital of $25,000, to manufacture chemicals, paints, etc. The incorporators are H. M. Underhill and D. F. Young. The company is represented by C. A. Hand, 123 Liberty St., New York.

THE LASO LABORATORIES, INC., 3733 North Clark St., Chicago, Ill., has been incorporated with a capital of $25,000, to manufacture chemicals, chemical byproducts, drugs, etc. The incorporators are Ludwig Sayfarth, W. C. McGuire and E. H. Nealis.

THE PREMIER RUBBER CO., Newark, N. J., has been incorporated with a capital of 50,000 shares of stock, no par value, to manufacture rubber products of various kinds. The incorporators are James A. Whitman, John W. Stoddard and W. Howard Demarest, 790 Broad St., Newark.

THE TROPICAL ENGINEERING CO., Tampa, Fla., has been incorporated with a capital of $30,000, to manufacture fertilizer products. S. W. Allen is president; and W. H. Phillips, secretary, both of Tampa.

THE LINCOLN SOAP & CHEMICAL CO., Bellevue, Pa., has been incorporated under Delaware laws with a capital of $75,000, to manufacture soaps, chemicals and chemical byproducts. The incorporators are E. Zane and W. H. Butterworth, Bellevue; and L. W. Bewby, Crafton, Pa. The company is represented by the Capital Trust Co. of Delaware, Dover, Del.

MILLER, MILLER & CO., INC., New York, N. Y., has been incorporated with a capital of $20,000, to manufacture chemicals and chemical byproducts; mineral specialties, etc. The incorporators are M., I., and B Miller, 950 Union Ave., New York.

THE ARGOL SULPHITE CO., INC., Curtis Bay, Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The company will commence the immediate erection of a new plant at Curtis Ave. and Birch St. The incorporators are John H. Moran, F. Swift Gibson and George A Whiting.

THE WALKER PETROLEUM CO., Wilmington, Del., has been incorporated under state laws with a capital of $5,000,000, to manufacture petroleum products. The company is represented by the Corporation Service Co., Equitable Bldg., Wilmington.

G. O. BEEMAN & CO., Detroit, Mich., have been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are George O. Beeman, Jr., and Charles W. Beeman, 3328 Whitney Ave., Detroit.

THE CONSOLIDATED COPPER MINES CO., Richmond, Va., has been incorporated with a capital of $2,000,000, to operate copper properties and manufacture refined copper. T. G. Pool is president, and George P. Royster, secretary, both of Richmond.

THE PAN-AMERICAN FIBRE CORP., Wilmington, Del., has been incorporated under state laws with capital of $1,000,000, to manufacture fiber products. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

THE OLEANDER PETROLEUM CO., Dallas, Tex., has been incorporated with a capital of $100,000,000 to manufacture petroleum products. The incorporators are J. H. Hill, F. M. Lege, Jr., and C. B. McKinney, all of Dallas.

M. DEMATTIA, INC., New York, N. Y., has been incorporated with a capital of $12,000, to manufacture chemicals and chemical byproducts. The incorporators are M. Lehman, F. Lowenfels and M. E. Schere. The company is represented by House, Grossman & Vorhaus, 115 Broadway, New York.

THE STANDARD GRAPHITE CO., Los Angeles, Cal., has been incorporated with a capital of $100,000, to manufacture graphite products. The incorporators are W. R. Morgan, Edward P. Jarvis, and K. R. Morgan, all of Los Angeles.

THE BROOKS CO., Utica, N. Y., has been incorporated with a capital of $25,000, to manufacture flavoring extracts and affiliated products. The incorporators are S. A., E. M. and V. E. Brooks. The company is represented by S. W. Brooks, Utica.

THE PETROLEUM OILS CORP., Kansas City, Mo., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are R. H. Erichsen, L. H. Schwald and H. J. Smith, all of Kansas City.

THE RESPESS PROCESS PAINT CORP., New York Division, New York, N. Y., has been incorporated with a capital of $1,000,000, to manufacture paints, varnishes, etc. The company is represented by the Corporation Service Co., Equitable Bldg., Wilmington, Del.

THE MICHIGAN FULLERS EARTH CORP., Hariette (Wexford County), Mich., has been incorporated with a capital of $400,000, to manufacture refined fullers earth and petroleum products. The incorporators are James E. Evans, Lakewood, O.; John Wall and Charles W. Hoffman, Cleveland, O.

THE STANDARD MAGNESIA MFG. CO., 613 Capitol Ave., Hartford, Conn., has filed notice of organization to manufacture magnesia specialties. C. H. Densmore heads the company.

THE WEST HAVEN RUBBER CO., West Haven, Conn., has been incorporated with a capital of $200,000, to manufacture automobile tires and other rubber products. The company has purchased the local plant of the Kelly Tire & Rubber Co. from the receiver for a consideration of $275,000, and will soon place the works in operation. The incorporators are A. F. Egner, J. A. Walsh and George F. Armstrong, president of the Armstrong Rubber Co., Garfield, N. J.

THE SOUTH RIVADAVIA OIL CO., Wilmington, Del., has been incorporated under state laws with a capital of $1,000,000, to manufacture petroleum products. The company is represented by the Corporation Service Co., Equitable Bldg., Wilmington.

THE UPPER LUBRICATION CO., INC., New York, N. Y., has been incorporated with a capital of $100,000, to manufacture lubricating oils. The incorporators are M. Ross, F. Hart and W. J. McGirr. The company is represented by W. H. Brady, 280 Broadway, N. Y.

THE UNITED FLUORSPAR & MINERALS CO., Pittsburgh, Pa., has been incorporated under Delaware laws with capital of $100,000, to operate fluorspar and kindred mineral properties and plants. The incorporators are Louis J. Adler, W. J. Strassburger and J. L. Hukill, Pittsburgh. The company is represented by the Delaware Registration Trust Co., 90 Market St., Wilmington.

THE SAINT ALBANS OIL CO., St. Albans, W. Va., has been incorporated with a capital of $30,000, to manufacture petroleum products. The incorporators are C. O. Nichols, A. G. Jacobson and Ward Harshbarger, all of St. Albans.

THE SUPERIOR PAINT & VARNISH CO., Wilmington, Del., has been incorporated under state laws with a capital of $50,000, to manufacture paints, varnishes, etc. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington.

THE PEP MFG. CO., New York, N. Y., has been incorporated under Delaware laws with a capital of $10,000, to manufacture abrasive compounds and kindred specialties. The incorporators are Eliot Norton, Alexander H. Jackson and Ralph Root, all of New York. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE NEW ENGLAND BRASS CO., 251 Fountain St., New Haven, Conn., has filed notice of organization to manufacture brass and bronze products. The company is headed by A. C. Stowe.

THE TWENTIETH CENTURY CHEMICAL CO., Boston, Mass., has filed notice of organization to manufacture chemicals and chemical byproducts. The company is headed by James Rea, 317 Adams St., Boston.

THE INDUSTRY OIL CORP., Houston, Tex., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are W. B. Harris and J. H. De Metro, both of Houston.

THE HERCULES SILICA ASPHALT CORP., Nashville, Tenn., has been incorporated under Delaware laws with a capital of $1,000,000, to manufacture special asphalts and kindred products. The incorporators are M. Brumbaugh, Brown Davis and W. B. Evans, all of Nashville. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington, Del.

THE MONUMENTAL CLAY PRODUCTS CO., 917 Munsey Bldg., Baltimore, Md., has been incorporated with a capital of $50,000, to manufacture brick, tile and kindred burned clay products. The incorporators are George H. Haines, Joseph J. Flynn and Edwin W. Herrmann.

THE MIDDLETOWN TIRE & RUBBER CO., Wilmington, Del., has been incorporated under state laws with a capital of $5,000,000, to manufacture automobile tires and other rubber products. The company is represented by the Delaware Charter Co., 904 Market St., Wilmington.

THE SUFFOLK DRUG & CHEMICAL CO., Medford, Mass., has been incorporated with a capital of $10,000, to manufacture chemicals, chemical byproducts, drugs, etc. B. G. Payzant is president; and John P. McKown, 12 Madison Ave., Medford, treasurer.

THE MUDDLETY VALLEY CLAY PRODUCTS CO., Hookersville, W. Va., has been incorporated with a capital of $10,000, to manufacture brick, tile and other burned clay products. The incorporators are Porter Herold, K. B. McCue and D. H. Fletcher, all of Persinger, W. Va.

THE BORDERLAND REFINING CO., Mirando City, Tex., has been incorporated with a capital of $30,000, to manufacture refined petroleum products. The incorporators are P. N. McCullough, J. G. Taylor and L. O. Gleason, all of Mirando City.

THE CENTRAL SILICA CO., 312 Maloney Bldg., Ottawa, Ill., has been incorporated with a capital of $20,000, to manufacture silica products. The incorporators are E. B. Wilkinson, A. H. Hall and R. I. Thornton.

THE CLEARVIEW BRICK CO., Clearview, Okla., has been incorporated with a capital of $30,000, to manufacture brick, tile and other burned clay products. The incorporators are James E. Thompson and J. W. Swain, both of Clearview.

THE BEACON SOAP CO., Beacon, N. Y., has been incorporated with a capital of $25,000, to manufacture soaps and affiliated products. The incorporators are I. Weiss, W. Hamberger and F. W. Mann. The company is represented by V. D. Stearns, Beacon.

WHITE & KLEPPINGER, INC., 2309 Archer Ave., Chicago, Ill., has been incorporated under state laws to manufacture soda, baking powders and kindred products. The incorporators are George H. White, Vernon A. White and John M. Kleppinger.

THE UNITED CHEMICAL PRODUCTS CO., Wilmington, Del., has been incorporated under state laws with a capital of $250,000, to manufacture chemicals and chemical byproducts. The incorporators are John P. Cann, M. N. Tyson and Henry McKeown, Wilmington. The company is represented by the Delaware Registration Trust Co., 900 Market St., Wilmington.

THE WILLMOTT OIL CORP., Okmulgee, Okla., has been incorporated with a capital of $400,000, to manufacture petroleum products. The incorporators are C. S. Willmott, John Caruthers and Joseph M. James, all of Okmulgee.

THE CLAY SERVICE CORP., Terra Cotta, Ill., has been incorporated under state laws with a capital of 1,000 shares of stock, no par value, to manufacture burned clay products of various kinds. The incorporators are Justus Chancellor, M. E. Gates and Justus Chancellor, Jr. The company is represented by Thornton & Chancellor, 1014 South Michigan Blvd., Chicago, Ill.

THE B. & R. LEATHER CO., New York, N. Y., has been incorporated with a capital of $30,000, to manufacture leather products. The incorporators are H. Rubin and E. Berkowitz. The company is represented by Herman Chaityn, 2 Cedar St., New York.

THE KNOX PORCELAIN CO., Wilmington, Del., has been incorporated under state laws with a capital of $370,000, to manufacture porcelain and affiliated ceramic products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE CRESCENT RUBBER MFG. & SUPPLY CO., Seattle, Wash., has been incorporated under state laws to manufacture rubber products of various kinds. The incorporators are William Rutherford and associates. The company is represented by Ryan & Desmond, 608 Pantages Bldg., Seattle.

Capital Increases, etc.

THE HAMERSLEY MFG. CO., 25 Park Place, New York, N. Y., manufacturer of waxed papers, with plant at Garfield, N. J., has disposed of a bond issue of $750,000, the proceeds to be used for general operations, extensions, etc.

THE MIDWEST & GULF OIL CORP., Tulsa, Okla., has filed notice of increase in capital from $5,000,000 to $10,000,000.

THE BORO CHEMICAL CO., Binghamton, N. Y., has arranged for an issue of 1,000 shares of common stock, no par value, for general operations, expansion, etc.

THE PLANTATION CONSOLIDATED OIL CO., Bowling Green, Ky., has filed notice of increase in capital from $350,000 to $850,000.

THE MIDWEST PAPER CO., 712 Federal St., Chicago. Ill., has filed notice of decrease in capital from $300,000 to $200,000.

THE SOUTH RIVADAVIA OIL CO., a Delaware corporation, has filed notice of organization to operate in New York, with a capital of 10,000 shares of stock, no par value. The company is represented by H. R. Stewart, 17 Battery Place, New York.

THE ATLANTIC FOUNDRY CO., Akron, O., has filed notice of decrease in capital to $985,300.

THE FARMERS' CO-OPERATIVE LIMESTONE CO., Branchville, N. J., has filed an involuntary petition in bankruptcy.

The plant of the FEDERAL OIL & REFINING CO., Oklahoma City, Okla., near Fort Worth, Tex., will be sold by J. C. Eagen, trustee in bankruptcy for the company.

THE THOMAS FURNACE CO., Kinnickinnic Ave., Milwaukee, Wis., manufacturer of pig iron, has arranged for a bond issue of $850,000, for general operations.

Plans are being perfected for a merger between the CUBAN-AMERICAN SUGAR CO., 129 Front St., New York, N. Y., and the NATIONAL SUGAR REFINING CO., same address.

Coming Meetings and Events

ALPHA CHI SIGMA fraternity will hold its seventh biennial conclave at the Marquette Hotel, St. Louis Mo., June 22, 23 and 24.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold a joint meeting with the Pacific Division of the Association, on the occasion of the annual meeting of the latter, in Salt Lake City, June 22 to 24.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Pittsburgh, Pa., Sept. 5 to 9.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 21, 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its summer meeting at Niagara Falls, Canada, June 19 to 22. Headquarters will be at the Clifton Hotel.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its nineteenth annual meet- at Bigwin Inn, Bigwin Island, in the Lake of Bays district, Ontario, Canada, on June 21, 22 and 23.

AMERICAN SOCIETY FOR STEEL TREATING will hold its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

ANNUAL SAFETY CONGRESS OF THE NATIONAL SAFETY COUNCIL will be held in Detroit, Mich., Aug. 28-Sept. 2.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NATIONAL FERTILIZER ASSOCIATION is holding its twenty-ninth annual convention at the Greenbrier, White Sulphur Springs, W. Va., this week.

NATIONAL LIME ASSOCIATION will hold its annual convention June 14-16 at the Hotel Statler, Cleveland, O.

NEW JERSEY CHEMICAL SOCIETY will meet at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

Markdown Sale In Technical Men

EVERY day now adds to the number of men trained in chemistry or chemical engineering who are embarking on their technical careers after finishing their college education. Therefore this is the time of year for retrospect and forecast. To one who has been in industrial work for a number of years and who has a pessimistic turn of mind, the entry of hundreds of young men into this particular profession is always a time for wailing and gnashing of teeth. "How many young men!" he cries. "What a large percentage of the total will remain mired in routine work and never rise to positions of authority or prominence or power!" To him let it be said that such is the case in any profession, in any walk of life. Few ever attain the top, and if many did attain the top, there would be yet another top to which only a few would attain. That need not be a ground for pessimism. It is a condition of our social and industrial order.

We ought, however, to remember this—that more of opportunity can be placed in the paths of men entering our profession and it lies in our power to do this. Some years ago a cry went up in the electrical industry that there were too many electrical engineers, and many sage comments were advanced at that time. Among them was the suggestion that the way out of the difficulty was to produce fewer electrical engineers. Fortunately for our industrial order, a wiser plan was evolved and more positions were made available for men trained in electrical engineering. Sales work, purchasing work, accounting work, non-technical work of many descriptions were opened to technically trained men in the electrical field. So it should be in chemistry, and now is the time to start! Even now, prophets are crying that we should diminish the number of chemical graduates. How foolish this would be, and yet how inevitable it is going to be if we do not find new outlets for them. Your company may need a salesman, or a purchasing agent, or a clerk in the purchasing office, or there may be openings in the cost-accounting department. Use your influence to get young technical men for this work. They will fall into it admirably and there is a big future for technical men in most of these fields. Perhaps you do not know of any opening. Search around and find out if there aren't openings in those departments. Young technical men will often be very glad to get the wages of a clerk in order to learn the ways of the department. They will be as well paid as they would be in a routine laboratory or as a beginner in a plant. Three months from now ask yourself this question (perhaps we shall ask it for you): How many chemists have I placed, how many of this year's crop, in either technical or non-technical work? To those who do not see a duty in this, we recommend a period of solitary meditation.

A Plot to Traffic In College Degrees

SOMETIMES the most innocent appearing advertisement leads to diverting circumstance and entertainment. Take for example the experience of a correspondent who answered an advertisement in one of the New York papers from someone who wanted to get in touch with people in South and Central America, either directly or through an agent having a wide circle of acquaintance in those countries.

In answer to the advertisement an appointment was made with the advertiser, who introduced himself as "Dr. SORGEN" and represented himself as president of a college in New Jersey, the name of which was unfamiliar and made no impression. Conversation opened in the approved manner, but the good doctor seemed loath to come directly to the business in hand and apparently preferred to spar for a round or two for the proper opening. The subject of education was brought up and naturally the conversation turned to college degrees. Did Dr. SORGEN'S auditor think that people in Central and South America were interested in higher education, and particularly in acquiring the coveted degrees granted to graduates and post-graduates of our higher institutions of learning? Sensing the possibility of adventure, our correspondent readily fell in with Dr. SORGEN'S line of investigation and assured him that the inhabitants of South and Central America deeply appreciated the advantages of higher education and had nothing short of a passion for the letters that can be tacked on to the names of those who rightly complete college courses.

With these preliminaries out of the way, progress was more rapid and Dr. SORGEN came to the point and proposed an alliance with our correspondent whereby he was to beat the bush in South and Central America for suckers for fake college degrees to be granted by Dr. SORGEN'S college. The proceeds were to be split on a 50-50 basis. The versatile doctor did not propose to confine himself to his own institution of learning, but he assured his prospective partner that engineering degrees, for example, could be obtained from a number of prominent institutions. Could he, for example, obtain the degree of Electrical Engineer from Massachusetts Institute of Technology? Yes indeed! But the doctor hastened to explain that a student could not pick the college from which to receive his degree, because they were given from different institutions in turn and one might catch Tech, while again he might get his degree from another college. Medicine, law, engineering, science and the arts were in the doctor's repertoire.

Efforts have since been made to entangle Dr. SORGEN in the meshes of the law, but he has developed a quality of wariness that has made it difficult to catch him. He declined to engage in correspondence

and apparently has dropped out of sight, preferring to forego the pleasure of bestowing degrees and granting diplomas for a stipulated sum—an avocation that ultimately might restrict his liberty. Our South American friends may well beware of "Dr. SORGEN" or any of his type who offers for sale the honorable evidences of an education earned in a reputable institution.

The War Is Over—
We Harbor No Malice

IN OUR ISSUE of March 8 we commented on "A German Chemist's View of Conditions in America." It had to do with an address he made in Germany after a visit to the United States, and now he writes to us in protest. We erred, he says, in translating some of his observations. We have mislaid the report, but are prepared to stand corrected, as he is a man of high character, wholly trustworthy and above dissembling.

The errors were not of leading importance. His protest is rather against the tone of our writing and the observations that we made of the curious workings of the German mind. His point of view is that the Germans want to be judged on their merits, in all fairness. and without the prejudice that he believes has been instigated here by "English and French lies."

The war is over, and we are resolved to be as generous as we can to Germans. We are all neighbors on the same earth, and we must get along together somehow. Like all the rest of the world they—and we too—are threatened with the "dictatorship of the proletariat," which means the rule of the incompetent, and this in turn means the breakdown of civilization which follows anarchy and disorder. We see it in Russia.

The difficulty in discussing Germany and Germans is due to a geographic difference in opinion. Outside that country the opinion prevails and always will prevail that Germany and the Germans stand guilty before the bar of the world's justice. To set down the indictment would only beget bad blood. We have no desire to do so. The German opinion appears to be the very opposite; that they, like others, participated in the great conflict, that they showed great bravery, and that they are no more guilty than any other participant. They do not ask for forgiveness, while we wonder that they are not ashamed. Some day when we know more than we do now we may be able to discuss the biology of opinion as a problem of calm, scientific research.

Once we were in a mixed company at lunch with the late THEODORE ROOSEVELT. A lady of the party who was an active social worker tried to steer the conversation over to some of the economic aspects of prostitution, and to get him to talk about it. The situation became rather tense. "Madam," said T. R. when her questioning had become categorical, "there was an old Frenchman who said that some subjects may only be discussed with safety in terms of statistics. I think he was right."

Our business has to do with pure and applied chemistry, and we do not discriminate whether it be of British, French, Italian, German or American origin. We take our hats off to the great work done by German chemists. They have added vastly to human knowledge and understanding. Let's stop right there and not upset the apple-cart by talking about what Germans did before and during the war.

A Significant
Chemical Merger

WE ARE in the midst of a season of mergers. Reports of combinations and consolidations are heard from all sides and in all industries. Just at present the public's attention is focused on the activities of the steel companies, but those of us in the chemical industry should not lose sight of a merger within our own ranks which would appear to carry with it more than usual significance. The purchase of the Condensite Co. of America by the Redmanol company, followed by the merging of both with the General Bakelite Co., is the climax of a remarkable story of industrial development. It is the outgrowth of the long-drawn-out litigation in which the courts broadly sustained the patents of Dr. L. H. BAEKELAND and recognized his pioneer work in the development of the commercial manufacture of synthetic resins and related products.

The chemical industry will be the first to welcome this amicable settlement of a historic controversy. We cannot help feeling that the merger opens the way to a wonderful opportunity for further progress and expansion. The constituent companies will continue on a competitive basis of manufacture; but there will be an exchange of information obtained in the several research laboratories. Thus the conditions will be most favorable for progress in the art of manufacture and for service to the industries consuming the product.

Mergers, for some reason or other, are always regarded with suspicion, and the present consolidation may arouse some criticism. However, if we have the right understanding of the Sherman law, it is not the actual consolidation of companies that is illegal, but rather the "combination in restraint of trade." From our own viewpoint, our respect for the technical men who are at the head of the new Bakelite Corporation and our confidence in their high-principled and able direction are such that we can look forward only to continued progress and increased service in this thoroughly American industry.

Dr. Jekyll
Boll Weevil

PROBABLY a very large percentage of the general public as well as the scientific and technical public believe that the boll weevil is the *sacre albion* of the South. In many ways this is true, but there is an interesting side of the boll weevil question which has received some publicity and deserves further emphasis as being a significant economic factor in the country. In many parts of the South the boll weevil cleaned out the cotton crop for several years and the planters in desperation began to plant other crops besides cotton. In this way they learned for the first time and of dire necessity the distinct advantage of being emancipated from the complete domination of old man cotton. As a one-crop district the South has always suffered. Planters had to bargain away their crops to brokers at a distinct disadvantage simply because they had no other weapons with which to bargain. Now in many communities with two or three or four other large crops cotton has still a major rôle, but it emancipates the planter from domination of the speculative buyer.

In one town in the South they have raised a statue to the boll weevil. This seems like a curious kind of grim humor, but the fact is that the town has for the first time in its career become a flourishing place, where

prosperity roosts occasionally. Previous to the invasion of the boll weevil the town was cotton poor. A good crop or a poor crop made very little difference. There seemed to be no large returns to the planter.

In this issue of CHEM. & MET. Mr. AMBRUSTER presents one phase of the fight which the government and the cotton planters are waging against the boll weevil. Calcium arsenate, the Nemesis of the boll weevil, developed by Dr. R. B. COAD of the Department of Agriculture and his energetic workers, is a peculiar commodity. Made from material which is a byproduct and whose value is not at all dependent on the demand, calcium arsenate has a price which is almost marginal as far as its use in cotton is concerned. Furthermore the cotton crop must compete for it with other crops which can afford to pay a much higher price for insecticides.

The fight against the boll weevil, however, is vital to the country's welfare and a knowledge of the conditions underlying that fight is most timely. The boll weevil has proved to be a Dr. Jekyll in waking some of the South to the folly of depending on one crop. He is essentially Mr. Hyde, however, and the war will stop only at extermination. At present calcium arsenate seems to be the way toward success.

The Demand for Steel Products in 1921

IN AN "off" year in the steel industry the demand for the different descriptions of steel does not decrease in equal proportions. Some steel products are relatively staple in character, while others exhibit wide fluctuations in demand from time to time. The full statistics of steel production in 1921, recently issued by the American Iron and Steel Institute, are of particular interest on this account.

It required no official statistics, of course, to inform us that the production of steel, as a whole, in 1921 was very light, but the exact measure is now furnished. The production of steel ingots was 19,184,084 gross tons, or less than half the production in 1916, 1917, 1918 or 1920. The backset was not only the greatest in tonnage but also the greatest in percentage ever experienced. In 1914 there was a 25 per cent backset from the best previous record, and in 1908 a 40 per cent backset.

The habit of thinking of steel production in terms of percentage of capacity is so common that this relation is given more importance than it deserves. Steel is so useful and its consumption is so interlocked with our various industrial and commercial activities that the amount of productive capacity is really only an incident. Considering the country as an industrial unit, we are engaged in consuming steel rather than in producing steel. It is the consumption that counts. It is a detail that the 1921 production was only about 35 per cent of the productive "capacity." It is very doubtful whether this "capacity" is really potential, whether it would today be possible to find enough transportation facilities and enough workmen to go with the production and consumption of steel at a rate equal to the physical capacity of the steel-making units. The existing "capacity" is more than double the actual production in 1910, which made a new record at the time, but the census reports only 9 per cent more persons "gainfully occupied" in 1920 than in 1910.

One of the most staple lines of steel production is the wire nail. As there were light exports in 1921, only 629,650 kegs, while five years in the past showed exports of more than 2,000,000 kegs, it is best to make comparisons by domestic consumption, which amounted to 11,259,762 kegs in 1921, or more than in any year prior to 1909, and only 22 per cent under the record, made in 1917.

Again, we may think of plates and sheets as not very different in character, but if we take sheets 13 gage and thinner and sheets and plates 12 gage and heavier (disregarding tin mill production entirely), we find that the 1921 production of 13 gage and lighter, 1,367,688 tons, was 54 per cent of the record output, made in 1920, and was greater than the output in any year prior to 1910, while the production of 12 gage and lighter, 1,804,453 tons, was only 33 per cent of the record, made in 1918, and was less than half the output in any one of the five years 1916 to 1920, while it was only 64 per cent of the output in 1910.

One may consider tin plate more of a staple than pipe, but pipe showed a very fair production in 1921, 1,987,442 tons, or 34 per cent under the record year, 1920, and 25 per cent under the second best year, 1916. Tin plate showed a production of only 793,198 tons, or only 52 per cent of the record output. The light production was largely because holders of goods packed in tin plate containers in 1920 at high cost were indisposed to liquidate by taking losses and named prices the buying public was unwilling to pay.

The Courage Of the Pioneer

IN THAT very charming comedy, "Little Old New York," there is a scene in which *John Jacob Astor*, the rugged Dutch leader of the community, upbraids a number of wealthy young men because of their unproductive and dissolute lives. "Habits such as yours," he scornfully remarks, "can never produce success such as mine." One of the young men protests to *Mr. Astor* that conditions are very different now from the time when he was a young man. There was more opportunity in those days. And yet young *Cornelius Vanderbilt* was just beginning his career at that moment. So it is with every generation. There appears to be no opportunity to most people until the pioneer has achieved success, and in achieving it reveals the opportunities that existed.

Besides vision it is necessary also to have courage. With vision only we have the dreamer who falls short of accomplishment. Courage is the energizer which picks up the dream and carries it to success.

Those who were fortunate enough to hear HERBERT DOW talk at the recent New York Section meeting of the A.C.S. on the early history of the company which now bears his name must be impressed with the high order of courage required to persist through the first five discouraging years of effort. When Mr. Dow described the fourth or fifth plant which he had built, and remarked, with a twinkle in his eye, "Well, that plant didn't work very well either," and then went on to describe some of the troubles which occurred, we all could laugh with him in his successful retrospect. But at the same time the fourth or fifth plant failed to produce, and when the embryonic company found itself again bankrupt, then was the time when, without courage, failure would have been inevitable.

The combination of vision and courage is rare. The reward of such a combination is inevitable. The inspiration, to the young chemist particularly, of the stories of such pioneers is beyond estimation. Let their stories be broadcasted.

Readers' Views and Comments

Spontaneous Formation of Martensite

To the Editor of Chemical & Metallurgical Engineering

SIR:—The article on "X-ray Data on Martensite Formed Spontaneously From Austenite," by Edgar C. Bain, is of much interest, but it would seem that further information and consideration are necessary before accepting some of the statements and conclusions contained therein.

The analysis of the steel would not seem to me to be such as could be retained in the austenitic condition at room temperature, and the micrograph at 100 diameters would scarcely seem to be of high enough power to make sure that the structure is really austenitic.

Some of the grain boundaries look very much as if the metal had been burned, which, of course, would outline the gamma grain boundaries, while the alpha boundaries would be inside the gamma ones. It seems to me, as stated before, that further information is necesssary before it should be so strongly stated that the original structure was austenite and that in the course of time the room temperature has changed this to martensite.

S. W. MILLER.

Union Carbide & Carbon Research Labs., Inc.
Long Island City.

To the Editor of Chemical & Metallurgical Engineering

SIR:—In reading over Mr. Bain's contribution to your issue of March 23 entitled "X-ray Data on Martensite Formed Spontaneously From Austenite" I am struck by the incompatability of his data, as presented, with previous experience. The chemical composition given would indicate that the steel used could not possibly have been austenitic, with so low a content of C, Ni and Mn. Since, however, the micrograph, Fig. 27, shows a characteristic austenite structure, it seems probable that there is a misprint in the analysis. Accordingly I asume that the nickel content is 28.1 per cent and not 2.81 per cent. On this basis the results become intelligible.

It is quite likely that a steel of that composition would be in the austenitic condition as cooled to ordinary temperatures and that it could be transformed more or less completely to martensite by appropriate treatment, but not by the action of time alone. Hanson and Hanson[1] give temperature vs. electrical resistance curves for iron-nickel alloys which show clearly this possibility. Their alloy of 25.5 per cent Ni content has its maximum of Ar_3 at 108 deg. C. and another of 29.4 per cent Ni content at —25 deg. C. An alloy corresponding to Mr. Bain's analysis but with 28.1 per cent Ni would probably behave like their 29.4 per cent Ni alloy because of its higher content of other lowering elements. It would then be austenitic as cooled to some ordinary temperature, but there is no existing data indicating that it would change appreciably to martensite with time if the temperature were kept constant.

However, there is a possibility that the specimen was subjected to the vagaries of weather. If severely chilled, it may very well have gone through the Ar_3 transformation. Mary Andrews[2] has shown very definitely the effect on the crystal structure of chilling by dipping a previously austenitic iron-nickel alloy in liquid air. Besides becoming magnetic, the specimen changed over to the body-centered cubic form.

Unfortunately Mr. Bain does not give a complete history of his specimen, so one cannot decide whether he has real evidence of a previously unknown "spontaneous" change of austenite to martensite or not. There are also several other inconsistencies which confuse the reader. Fig. 1 is evidently not of the same area as Fig. 2. Whether the illumination is vertical or oblique, the grain contrast should show in it and twins would be expected also.

The apparent difference in grain size also requires explanation. It is not stated whether Fig. 6 is the result of repolishing and etching or is the original etched and polished surface. If the latter is the case, no definite change in the surface appearance would be expected to be visible at the magnification used, even though the specimen changed completely from austenite to martensite. Figs. 8 and 9 are evidently reversed. In consequence of this situation it can scarcely be held that the data presented bear out the implication of the title.

Bureau of Standards,
Washington, D. C.

HOWARD SCOTT.

To the Editor of Chemical & Metallurgical Engineering

SIR:—The paper entitled "X-Ray Data on Martensite Formed Spontaneously From Austenite" in the issue of CHEM. & MET. for March 22, 1922, was written not so much to establish spontaneously transformation as to present observations corroborating the view that martensite is essentially a fine-grained material.

Jeffries and Archer have offered this theory and the data afforded by the author's X-ray crystallographs verify it in a way which probably could not have been accomplished by the microscope.

It is only incidental that martensite with apparent grain size many times the true grain size—a condition desirable for the proof—was found in an unusual specimen. A quench from the melting point made so quickly as to hold a steel largely austenitic with relatively low content of the agents carbon, manganese and nickel is rather unique and it was thought that this fact might lend interest to the account. The author has been able to produce very nearly pure austenite from ordinary high-carbon steel with insignificant content of manganese and nickel by quenching in iced brine and these specimens also lost the face-centered cubic crystallinity by transformation to body-centered iron at room temperature after the lapse of several months.

The microphotographs were made to show the twinned structure characteristic of austenite in one case and the absence of the "chevron" markings of martensite at the higher magnifications. These were of course made on the freshly quenched material. Doubtless the change began very soon after quench.

Unfortunately, the numbers designating figures 8 and 9 were interchanged, probably due to an oversight in reading the proof of the article.

Calcium Arsenate for Boll Weevil Control, and the Arsenic Situation

The Insect Infestation of the Cotton Fields of the South Has Developed a New Branch of the Chemical Industries, the Growth of Which Will Be Controlled by Many and Conflicting Factors, Including the Available Supply of the Principal Raw Material

By HOWARD W. AMBRUSTER

THE insect pests as a group are said to be the most powerful enemy of mankind today, the hazard to humanity being the starvation of the peoples of the earth through reduction of crops. And that part of the chemical industry which is devoted to the production of compounds for the destruction of insect pests is believed by those engaged in it to be the most hazardous of any industry based on applied chemistry from every standpoint. Of the insect pests which have been identified and combated by the combined ingenuity of agriculturists, entomologists and chemists, none has attained more prominence or greater disrepute than the Mexican, or cotton, boll weevil (*Anthonomus grandis*), which, though it does not attack a food crop, is equally as destructive from an economic standpoint as any insect now known. In the battle for the control of the boll weevil in the cotton states of the United States, after many methods have been tried by government officials and private investigators, the greatest encouragement that has resulted has been from the use of the compound known as calcium arsenate, $Ca_3(AsO_4)_2$. This product, made by the combination of arsenic acid and lime, is now manufactured in this country by about fifteen or twenty of the companies making agricultural insecticides.

Is a Shortage of White Arsenic Likely?

The probable increase in demand for calcium arsenate for boll weevil control has brought up the question as to whether the supply of commercial arsenic which is now available in this country and abroad is sufficient for any such quantity of calcium arsenate as some enthusiasts claim will be required annually within the next few years.

There are so many different factors, statistical and otherwise, which must be considered in reaching any conclusions on this subject that the latter are bound to be more or less controversial. But some phases of the situation are sufficiently defined to permit the contention that an acute shortage of arsenic probably will develop should the demand for calcium arsenate reach any sizable proportions. It must be acknowledged also that should the production of arsenic remain stationary, while the demand for calcium arsenate increases, the future program of the entomologists for the use of this spray for the cotton crop will be endangered.

That feature of the situation which is not appreciated by many of those directly interested in the industries affected is the fact that at present the world's available production of arsenic has no relation whatsoever to the market demand for the product. In this respect arsenic is somewhat unique among those products or commodities which may be described as basic raw materials. The white arsenic of commerce, or "arsenic oxide," is more correctly arsenic trioxide, As_2O_3 (also known as arsenious acid and arsenious anhydride). Practically all of this arsenic which is produced today is the byproduct of the smelters. It was first produced in the crude state at the smelters in what are known as bag houses attached to the furnace flues and in more recent years by the Cottrell process by electrical precipitation of the arsenical or black dust from the smelter fumes.

As the attorney said in advising his client, the latter's case had a "nuisance value" which made it worth while; just so is the arsenic production regarded by metallurgists and smelters. It is a nuisance and has a nuisance value only. It is usually regarded as the most objectionable content of the precious and semi-precious ores, and any ore is selected for its low arsenic content in preference to another ore equally available and valuable but containing a higher percentage of arsenic. It will be conceded generally that if it had not been for the legislation directed against the smelters on account of the damage done by their fumes, the use of arsenic as an agricultural spray material would have been seriously retarded from its inception for lack of sufficient supply of the raw material.

Method of Manufacture of White Arsenic

The crude arsenic as it is first collected varies in content all the way from 40 to 90 per cent As_2O_3, though the bulk of it approximates the higher level. To refine it to 99 per cent so that it is marketable as white arsenic, the crude must be treated one or more times in volatilizing furnaces, by which process the other ingredients in the original crude product are separated and driven off with the exception of a minimum ½ to 1 per cent of impurities which are found in all commercial white arsenic. The crude product varies greatly in percentage and character of impurities which are at times extremely difficult to reduce, and the smelters therefore sell a certain percentage of their output as off-grade arsenic testing between 90 and 99 per cent.

This off-grade arsenic can be used for a part of the market requirements, but is unsuitable for the most important use, which is the manufacture of arsenic acid, or H_3AsO_4, the first step in the production of the important arsenical insecticides, lead and calcium arsenate.

It should be obvious, therefore, that in case of sudden increase of the demand for arsenic we shall have to look elsewhere than to the smelters, which produce the crude because they cannot help themselves and refine it to make it marketable. The selling price has, therefore, no relation to the cost, but reflects in a way

an open bidding by the consumers for the given tonnage of arsenic which is available each season.

The real cost of production comprises, first, the transportation of the crude to the refining plant, the revolatilizing cost, which varies according to the number of treatments required, grinding if the product has solidified in the flues, and packaging for the market. If as an accounting policy a part of the actual cost of smelting is allocated to the arsenic byproduct as such, a considerable item may be added to the total cost of the refined white arsenic, and as the latter is now a standard market commodity of wide distribution, it is of course an entirely logical policy to divide total operating costs among all of the various products of the smelters. But this point should be taken into consideration when considering the actual cost of production in relation to selling price.

The direct production of arsenic from some of the many low-grade iron ores (mispickel or arseno-pyrites) containing a fairly high percentage of arsenic has been commercially attempted many times, but never with sufficient success to insure a stable enterprise. Should the demand increase to such a point as to put the market on a permanent level, about double its present selling price (6 to 7 cents per pound), many of these developments could undoubtedly be firmly established, but any such increase in the selling price of arsenic would seriously affect the cost of manufacture of calcium arsenate as well as all other arsenical spray materials. Calcium arsenate for boll weevil control must be sold at an even lower figure than it is at present to insure the utmost development of its use and value to the South.

On the other hand, spray materials for all other purposes and likewise all other uses for white arsenic, should necessity demand, can afford to pay increasing prices. This has been demonstrated in the recent past. So while it is a safe conclusion that the direct production of arsenic is a possible development at a higher price level for many other requirements, it does not follow that the increased supply thus made available will contribute to the protection of the cotton crop. Aside from the various known methods of direct production of commercial arsenic from mispickel, the only other alternative is the possible development of the production of arsenical compounds for spray requirements direct from an arsenical ore.

Use of Arsenate Ore as Short Cut

A short cut to the final product precludes the process of extracting the arsenic as As_2O_3 and its subsequent oxidation to As_2O_5, and requires an ore in which the arsenic is present in its natural state as an arsenate instead of an arsenite. Deposits of the latter classification are found in many parts of the United States and elsewhere, but there is only one known deposit of the former in any appreciable quantity, and its development, though contemplated for some years, is still in the future as a commercial enterprise. A very considerable saving in final cost would result should it prove to be practicable to produce the commercial arsenical sprays such as calcium and lead arsenate direct from an arsenical ore and without the successive steps of refining white arsenic and converting the arsenic to acid before combining with the lime or lead.

Extent of Market

Of the 16,000 tons of arsenic which it is estimated is now consumed annually in the United States, between 80 and 85 per cent is required by the insecticides and related industries such as the manufacture of weed killers and cattle dip. The bulk of the remainder of the total goes to the glass maker and for the manufacture of pharmaceuticals. Of the requirements for insecticides the largest part is converted into arsenic acid in about twenty-five different plants mostly located in the East and Middle West. The majority of these are small and operate only a few months in the year. The same intermittent schedule of operation applies to the other plants, about twenty in number, including those which compound spray materials like paris green direct from the white arsenic and those making weed killer and cattle dip. This irregularity of consumption has always brought the maximum demand within a few months for a basic raw material which is produced normally over the entire twelve months. The effect on the market price is obvious.

The other principal demand for arsenic, for the glass industry, is an all the year round requirement, as is also the limited use of arsenic acid for the production of arsepheminine, or salvarsan, and small requirements such as for rat poisons, preserving hides and the reduction of metallic arsenic. In times past arsenic was an important raw material for the dye industry, it being used in the production of fuchsine colors, but this method has been abandoned, and the industries enumerated above cover practically all the uses to which arsenic is now put.

Official figures indicate that the present production of byproduct arsenic in the United States is at the rate of approximately 12,000 tons annually, and the remainder consumed here comes mainly from Canada and Mexico and from Germany, Japan and Belgium.

The figures for the world's production of arsenic are exceedingly difficult to compile intelligently, as official statistics are irregular in classifying white arsenic with the crude, with ore content and with red arsenic and with the metal itself.

From such figures as are available, however, it is evident that the annual production of commercial white arsenic from all world sources is not much in excess of 30,000 tons when the smelters are at normal production, and the total is probably less than that figure during the last two years of restricted metal output.

A large quantity of arsenic was imported into this country in years past from Spain and England, as well as from Germany, but more recently the English supply has been consumed at home or gone elsewhere, and unsettled conditions in Europe since the war have permitted the Japanese producers to make considerable inroads on the importations to America. In addition to the countries named, arsenic is also produced in South Africa, Australia, Greece, Portugal and France, but in none of these countries is there any surplus for export to the United States.

The demand abroad is fairly stable and the uses are similar to those in the United States, though a much larger proportion of the total is consumed by the industries other than the agricultural sprays. Of the latter broad classification the use of arsenic for cattle dips is in much greater proportion abroad than in the United States. In South Africa, South America and Australia, where cattle raising is highly developed, the use of arsenic for dips preceded this use in the United States. All agricultural countries are using insect sprays in a greater degree than ever before, though nowhere to the same extent as the American farmer

and fruit grower. The cotton planter abroad has his own weevil problems to help along the consumption of arsenic. There is no reason to believe, therefore, that a normal or steady increase in the world's consumption of arsenic will not keep pace with any possible normal increase in the byproduct production of the smelters, and this leaves a margin of only a few thousand tons available at present prices for any abnormal increase in demand which the situation in the South may develop.

Loss Caused by Weevil

Anything like an exact estimate of the actual loss caused by the boll weevil must be an exceedingly argumentative conclusion, based on unreliable premises. The shiftless planter blames on the weevil everything which he cannot unload on the weather and the cotton traders; the intelligent cotton raiser in boll weevil districts tries every precaution or remedy recommended by government and state officials and admits that the weevil is at least largely responsible for the difference between a minimum and a maximum yield per acre. However, there can be no valid objection raised to the statement that the loss to the cotton grower due solely to the destruction by this one pest has already reached a total of hundreds of millions of dollars.

Poor Quality of Early Product

When the use of calcium arsenate was first advocated a few years ago, a number of manufacturers began to produce it. The quality of this first material was so irregular, however, that a great deal of distrust was developed, and this retarded greatly the use of calcium arsenate. In some sections the cotton crop was seriously injured by the high percentage of soluble arsenic. The resulting prejudice is so strong that it is very doubtful if the government can ever altogether overcome it. In addition to the poor quality of the product, the lack of knowledge of how to apply it also caused considerable damage to the cotton crops. It is perhaps not unnatural that the ignorant negro planters cultivating a few acres of cotton should be slow to learn the proper way to use the insecticide. Chemical manufacturers, however, have not the excuse of ignorance which the poor negro planter has and it is therefore not unreasonable to expect that they should have known better. The manufacture of calcium arsenate according to the chemical and physical specifications recommended by Dr. Coad, the government entomologist, is not a difficult problem, but many producers have found its manufacture tricky and many tons of material have been condemned by government agents.

Present Production and Future Estimate

The production of calcium arsenate thus far reached its high point in 1920, when upward of 5,000 tons was manufactured in the United States. Much of this was made too late for the 1920 season, and was carried over for 1921. On account of the condition of the South last year, the use of this spray did not develop as expected, and part of the 1920 production was carried in stock for the second year. In some quarters it is felt that the prospects this season are for an extremely heavy demand. The manufacturers, with last year's disastrous losses in view, have declined to pile up any new accumulation of stock ahead of the selling season, and it is entirely possible that the demand this season will exceed the available supply, though this is not likely, as there are large stocks in the Southern warehouses of many companies.

Such manufacturing capacity as the plants now have, if operated continually through the year, would be more than ample for any possible demand at present. In the recent past, however, the erratic market records for the product itself and for white arsenic, the principal raw material, have made it unwise to anticipate the demand before it actually comes about.

It is improbable that this marketing condition will continue to prevail should the demand for calcium increase as expected. But the estimating of just what the possible or probable increase shall be has led some of the producers far astray in the past and will probably continue to do so for years to come. One enthusiast in the early years of the use of calcium arsenate based his calculations on the number of acres planted in cotton in the South and the maximum amount of calcium arsenate which could be used per acre. The result was startling, and disastrous to those who were influenced by the figures. There was not enough manufacturing capacity available, or enough white arsenic in sight, to produce in a long period of years the amount of calcium arsenate which would be consumed in a single season on the basis of this simple calculation. Far below the figures of that brilliant statistician is a conservative estimate for the ultimate consumption of calcium arsenate. When that time will be reached and whether more effective means will be devised in the meantime only a reckless prophet would predict.

Problem of Price

It would be somewhat desirable to get a rough estimate of just how the price of calcium arsenate affects the extent of its use. Official recommendations from the Department of Agriculture advise the use of about 5 lb. of arsenate of lime per acre and at least four applications during the season, if the weevils are actually damaging the crop. Calcium arsenate now sells at from 9 to 12 cents a pound, which represents more than half of the total cost of dusting the cotton. Assuming that we dust four times in a season and use 5 lb. per acre at 10 cents a pound, the poison alone would cost $2. Adding $1.50 for application, the total expense per acre would be between $3 and $3.50. When it is realized that the average yield per acre is a third of a bale and that cotton has been selling for as low as $50 per bale, it is seen that the cost of applying the spray may represent a very considerable percentage of the selling price of the cotton. Dusting with arsenate of lime pays the farmer well if the control is successful and if the yield is a bale per acre or over, as it is in the heart of the Delta cotton belt. In the poorer sections, however, the situation is very different, and a planter who cannot hope for over a quarter of a bale per acre would really just about as soon have the boll weevil eat his cotton as have his profits go to the manufacturer of calcium arsenate. If the price of arsenate of lime could be cut in half, this would very naturally extend its application to the poorer fields. Likewise, when cotton is selling at a high price, the cotton planter can afford to buy calcium arsenate, when otherwise he could not. It is not a simple problem, but one which involves considerable guesswork as well as experience in the yield of the particular land which the planter is cultivating.

Another handicap to the development of the use of

calcium arsenate is the method of marketing the product, which has been both erratic and expensive. The product, being an agricultural spray material, has been handled along similar lines as other insecticides, the sale of which is largely a package proposition. Calcium arsenate is a spray material, but as a marketing proposition for boll weevil control it must ultimately be sold on a tonnage basis and the margin for sales expense and middleman profit must be reduced to the minimum permitted for fertilizers and similar products. Time will bring about this change in the natural course of events, and the State of Georgia in a way has forced the issue this season by purchasing direct from a manufacturer and distributing to the planter at cost.

The production of calcium arsenate must be classified at present as an "infant industry," but it is evident to any careful investigator of all phases of the situation that a demand for a great many thousand tons will develop in the next few years if the price is low enough.

Summary

For every hundred pounds of calcium arsenate which is made, approximately 40 lb. of white arsenic is necessary. The supply of white arsenic annually consumed by this product thus far is not large, but it is an appreciable percentage of the total supply, which, it must be remembered, is a relatively stationary quantity. The use of calcium arsenate for the boll weevil will increase, but at a rate which cannot be anticipated. It will depend upon the supply of arsenic which is available, upon the price of cotton, upon the yield of cotton per acre and upon the price of calcium arsenate itself. In addition, other uses of calcium arsenate are increasing from year to year, notably those which have to do with truck garden produce. Finally, calcium arsenate has been recently recommended as an effective means of preventing the alfalfa weevil from spreading. It is barely possible that this use may eclipse the use of calcium arsenate as a cotton insecticide. Other uses of white arsenic in various insecticides are also increasing, and these uses can easily outbid the cotton market for the available white arsenic. It will be seen, therefore, that many factors enter into the use of calcium arsenate as a cotton insecticide. Besides those already mentioned in this summary, we must refer to such things as the fashions for cotton fabric, the smelting of semi-precious metals, the education of the Southern darky and many others far afield from chemical engineering.

Lead Pigments Marketed in the United States in 1920 and 1921

The following table shows the quantity and value of lead pigments marketed in the United States in 1920 and 1921 as reported by producers to the United States Geological Survey.

LEAD PIGMENTS MARKETED IN THE UNITED STATES

	1920			1921		
	Short Tons	Value — Total	Value — Per Ton	Short Tons	Value — Total	Value — Per Ton
Sublimed lead:*						
White	12,412	$2,033,647	$167.87	11,568	$1,418,403	$122.61
Blue	928	153,657	165.58	463	58,593	126.55
Red lead				21,814	3,410,904	156.36
Orange mineral	34,431	7,523,089	218.50			
				379	91,184	240.59
Litharge	62,329	12,386,185	198.72	41,953	5,740,690	136.84
White lead:						
Dry	33,678	6,351,798	188.60	26,695	3,749,851	140.47
In oil	112,017	25,986,100	231.98	143,634	27,713,257	192.94

Petroleum Refineries in the United States

Of the total of 479 refineries, with a capacity of 2,109,700 bbl., reported by the U. S. Bureau of Mines as existing in the United States Jan. 1, 1922, 31 plants with a capacity of 759,000 bbl. were complete refineries representing 36 per cent of the total capacity, according to a compilation made by the American Petroleum Institute based on the data of the Bureau of Mines.

There were 251 skimming plants, with a capacity of 636,890 bbl., representing 30.2 per cent of the total capacity.

Skimming and lubricating plants numbered 56, with a capacity of 186,950 bbl., representing 8.9 per cent of the total capacity.

Wax plants numbered 51, with a capacity of 187,260 bbl., or 8.9 per cent of the total capacity.

There were 7 skimming and asphalt plants, with a capacity of 89,700 bbl., or 4.3 per cent of the total capacity.

There were 9 topping plants with a capacity of 68,800 bbl., representing 3.2 per cent of the total capacity.

Skimming, lubricating and asphalt plants numbered 3, with a capacity of 45,000 bbl., or 2.1 per cent of the total capacity.

There were 7 asphalt plants with a capacity of 33,850 bbl., or 1.6 per cent of the total capacity.

Lubricating plants totaled 12, with a capacity of 18,000 bbl., or 0.8 per cent of the total capacity.

Forty-seven plants with a capacity of 50,050 bbl., or 2.4 per cent of the total capacity, were unclassified.

The following table shows the capacity percentage rank of the various types of refineries as classified by the Bureau of Mines:

PETROLEUM REFINERIES IN THE UNITED STATES

Kind of Plant	Total — No.	Total — Capacity Bbl.	Total — Per Cent of Combined Capacity
Complete	31	759,000	36.0
Skimming	251	636,890	30.2
Skimming and lubricating	56	186,950	8.9
Skimming and asphalt	7	89,700	4.3
Skimming and coke	4	22,200	1.0
Skimming, lubricating and asphalt	3	45,000	2.1
Skimming, lubricating and coke	1	12,000	0.6
Wax	51	187,260	8.9
Lubricating	12	18,000	0.8
Asphalt	7	33,850	1.6
Topping	9	68,800	3.2
Unclassified	47	50,050	2.4
Total	479	2,109,700	100.0

An Exceptional Industrial Safety Record

Total elimination of accidents during 1921 without a minute lost time by workmen is the record established by the 124 employees of the H. H. Robertson Co. plant at Ambridge, Pa. Recognition of this unusual accomplishment was made at the fourth annual banquet of the Western Pennsylvania division, National Safety Council, through the presentation of the Rice Safety Award bronze tablet to the employees of the company. The award was accepted on behalf of the employees by W. E. Megraw, safety director.

This record is particularly interesting because in addition to the usual industrial hazards, employees are constantly unloading and handling steel sheets, coating them with asphaltic compounds heated to from 300 to 400 deg. often under severe fume conditions, moving the sheets and finished product from place to place and at times working on lines through which hot oils are piped.

Modern Methods of Concentrating Sulphuric Acid*

Methods in General Use and a Newly Developed Apparatus of the Submerged Hot Air Type With Particular Reference to Its Application in the Concentration of Separated Sludge Acid From Oil Refining

BY PETER S. GILCHRIST
Chemical Construction Company

CONSIDERABLE study of sulphuric acid concentration has been made by different chemical engineers during the last few years, stimulated, to some extent, by the heavy demand occasioned by the war. Instead of small units of 5 to 10 tons capacity per day, we now think of units of 80 to 125 tons capacity per day, the large units requiring no more labor than was required for the smaller units and, at the same time, operating with greater economy of fuel.

The advent of the Glover tower gave chemical engineers the idea of using the principle of the Glover tower for the higher concentration of acid. Today the tower system and the combined tower and surface evaporation systems of concentration are the methods in most general use, especially for concentrating chamber acid.

Owners of plants for the concentration of chamber acid, or the reclaiming of contaminated sulphuric acid, are today looking for equipment that will operate without too many unnecessary shutdowns for repairs, and that can be operated with the least possible labor.

The principal features to be considered when planning the installation of a concentrator are the following: A reasonable investment for the owner, durability of the equipment, minimum labor, low consumption of fuel and power, high recoveries and elimination of waste fumes.

The use of fuel oil as a heating medium for evaporation and the perfection of the oil burner so as to get absolute combustion have made it practical to apply the direct heating principle for evaporating, without discoloring or contaminating the acid.

The use of more permanent construction materials has reduced to a minimum the maintenance and labor costs. For instance, a vast amount of concentrating is now being done in baths by the direct-heating principle and in towers where the principal item of construction is acidproof masonry. The adoption of acidproof iron for overflows and transfer lines for hot strong acids has been very advantageous.

In this paper the antiquated pan, still and bottle systems are eliminated, confining the description to the following systems: (1) Cascade. (2) Tower system. (3) Combination surface evaporation and tower concentration. (4) Hot air submergence type. These four methods, especially the last three, are the ones used principally in modern plants.

DESCRIPTION OF CONTINUOUS CASCADE SYSTEM

In this type of concentrator we have the application of indirect heat for evaporation. The heat can be supplied with oil, gas, coal or coke. The combustion gases do not contaminate the acid, as the pans are heated from the under side, the hot gases not coming in direct contact with the acid. This type consists of a series of pans, or dishes, in several rows, each row a step higher than the preceding one in order that the acid may enter at the top pan and overflow by gravity from one pan or dish to the other until it is sufficiently concentrated. The heat is applied at the acid outlet end, at which place is located the lowest row of pans. The pans or dishes are supported on open seats which are directly exposed to the heat.

The three or four lowest dishes in each series are protected by bowls from the direct heat, so as to prevent violent ebullition and spurting of the acid. The acid vapors are drawn off by an exhauster and condensed. The loss by fumes is apt to be greater with this system than with the tower system. The cascade apparatus is designed so as to get at each dish or pan readily in case of breakage. A cracked or broken pan necessitates an interruption in the flow of acid, in addition to the loss of acid sustained. The advent of the vitreosil dish, which has a very low coefficient of expansion, has very materially reduced the losses by breakage. It is claimed that the breakage of vitreosil dishes is about 5 per cent and the pans 1 per cent. A. E. Wells and D. E. Fogg[1] described a 10-ton plant with one hundred dishes 12 in. in diameter and 60 preheating pans 24 x 12 in. for concentrating acid from 60 to 66 deg. Bé. They give the cost of concentration as follows:

Coal, 17 per cent at $5.00 per ton	$0.85
Labor	1.25
General expense and repairs	1.00
Losses, 4 per cent of acid, assuming 60 deg. Bé. acid at $8.00 per ton	.30
Operating cost per ton of 66 deg. Bé. from 60 deg. Bé.	$3.40

For comparison with other estimates following in this paper, it is to be noted that 17 per cent of a ton of coal, or 340 lb., is equivalent to 245½ lb. oil, or 32.3 gal. Then 32.3 gal. oil at 4c. per gal. equals $1.29, or an increase of 44c. in fuel cost per ton of acid, making the total cost on the basis of Wells' and Fogg's figures $3.84 per ton.

DESCRIPTION OF COMBINATION CASCADE AND TOWER SYSTEM

Combinations of cascade and tower systems have been used. An installation at Baltimore in 1916, with twelve iron pans 36 in. in diameter, in two rows, produced 23 tons of 66 deg. acid per 24 hours from 54 deg.

*A paper presented before the Acid Symposium at the fourteenth semi-annual meeting of the American Institute of Chemical Engineers, Niagara Falls, Canada, June 19 to 22, 1922.

[1] "The Manufacture of Sulphuric Acid In the United States," Bulletin 184, Department of the Interior, p. 137.

Bé., the acid entering the top pans being 57 deg. Bé. at 290 deg. F. Actual operating cost per ton of acid is as follows:

Fuel oil, 19.5 gal. at 4c.	$0.78
Labor	.71
General expenses and repairs	.85
Losses, 10 per cent of acid, assuming 60 deg. Bé. acid at $8.00 per ton	.80
Operating cost per ton of 66 deg. from 54 deg. Bé.	$3.14

Description of Tower System

In this type of concentrator the entire concentration is done in a tower. The tower is partly filled with suitable tower packing. The combustion gases enter at the bottom of the tower, and as they ascend they meet the downcoming acid in the tower, the exit of steam and gases being made at the top of the tower.

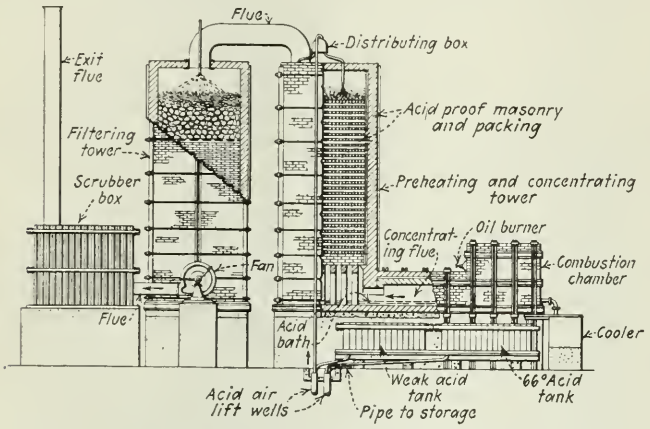

FIG. 1—COMBINATION SURFACE EVAPORATION AND TOWER TYPE FOR CONCENTRATING CHAMBER ACID

The weak acid is sprayed in at the top, and the strong acid settles in a basin at the foot of the tower. It is interesting to note that in this type of concentrator the entire volume of hot air comes in direct contact with the acid, thus keeping the strong acid at its actual boiling point. This has the disadvantage that the hot gases of combustion play directly on the arches and tower packing before the gases have much chance to cool.

The depreciation on the apparatus for this method of concentration is very reasonable, due to the tower being made of acidproof masonry work, but it is understood that the lower part of the packing has to be renewed occasionally, as it will burn out due to the high heat. Results from this method are claimed to be 1 ton of 66 deg. acid from 60 deg. with 11 to 12 gal. of oil.

Description of Combination Surface Evaporation and Tower System

It was found years ago that the method of surface evaporation, or direct heat application, was much more efficient than the indirect application of heat, such as with pan or still systems. Surface evaporation was not very practical before the advent of the oil burner, as absolute combustion is essential to success. The principle of tower concentration is well known. In this combination type concentration is accomplished (1) by surface evaporation, (2) by tower evaporation and preheating. The weak acid is sprayed in at the top of the tower. The upper portion of the tower does the preheating and the lower portion the preliminary concentration. The tower is packed with suitable packing materials. The acid falls from the tower into a long horizontal flue containing a bath of acid, over which the hot gases pass. The combustion gases enter the flue at the acid outlet end and pass along the surface of the acid to the foot of the tower, where they pass up through the interstices of the tower packing, meeting the downcoming weak acid. The tower is of sufficient height and size to utilize the remaining sensible heat of the combustion gases. The greater part of the concentration is done in the pan flue, where the acid is brought to maximum strength. The bath of acid is about 9 in. deep, and as the hot gases are brought into immediate contact with the surface acid, the acid takes up the heat much better than when the acid and heat are separated by metal plates, as is the case with cascade or pan systems. Evaporation is very greatly assisted by the direct heat over the acid, as the draft quickly removes the vapors formed. The finished acid leaves the concentrator at the furnace end, temperature about 50 deg. F. below the actual boiling of the acid, which is strong evidence of the efficiency of this system. Because of low heat reaching the tower, the apparatus itself has a very long life and the tower packing proper will last as long as any of the apparatus.

The principal apparatus of this concentrator consists of a combustion chamber, a concentrating pan flue, concentrating tower, filter and scrubbing tower, all of which are constructed of acidproof masonry, well braced with steel framing and supported on concrete or brick foundations at a suitable height above the ground level. On top of the concrete foundations, masonry-lined lead pans are used, on which are built the masonry walls. The concentrating tower is packed with checkered brick, quartz or other suitable packing, and the

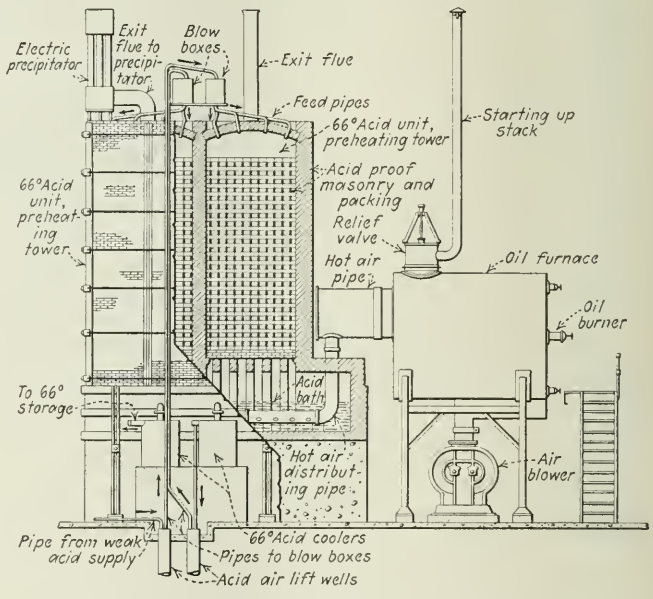

FIG. 2—HOT AIR-SUBMERGENCE TYPE UNIT FOR CONCENTRATING SLUDGE ACID FROM OIL REFINING

filter tower is packed with 3 in. special rings, or quartz. If the packing materials are carefully selected, the distillate from the tower can be sold for battery acid and other similar uses.

Two 50-ton units of this type concentrator were installed nearly 5 years ago at Bayonne, N. J., for the

Standard Oil Co. Recent figures have shown that over this protracted period of operation the consumption of oil was from 10 to 11 gal. per ton of 66 deg. acid starting from 55 deg. Bé. During a period of a little more than 4 years, over 140,000 tons of 66 deg. acid was turned out with a repair and upkeep cost of less than $10,000. This gives the cost of repairs and upkeep at 7c. to 8c. per ton of 66 deg. acid. One man per shift operates the entire plant. Cost of operation is as follows:

Fuel, 11 gal. at 4c.	$0.44
Labor	.12
General expenses and repairs	.30
Losses, 3½ per cent based on $8 per ton of 60 deg. acid	.28
Operating cost per ton of 66 deg. acid from 54 deg. Bé.	$1.14

The labor per ton for large plants is naturally less than for small plants.

This system of concentration is especially adaptable for making 98 per cent acid, on account of construction. The apparatus can easily withstand the higher temperatures encountered in the final stage of concentration. In bringing acid to 98 per cent strength, provision has to be made for taking care of the additional distillate, and naturally the output of acid decreases and the oil consumption increases.

Description of Hot Air Submergence System

Especially in the concentration of sludge acid it is necessary to accomplish concentration at the lowest possible temperature, because the acid to be concentrated is contaminated with carbonaceous matters which, in company with strong hot acid, quickly causes the breaking up of the acid into SO_2, it being well known that 1 lb. of carbon will break up 16 lb. of acid. Heretofore the pans have been used mostly for the concentration of sludge acid, but the cost is almost prohibitive, and in some cases when using the pan system the cost of concentration exceeded the cost of new acid. The cost of concentration by this new method of hot air submergence in some instances has reduced the cost of the 66 deg. recovered acid to one-third or one-fourth the cost of new acid.

This hot air submergence type of apparatus is designed to concentrate any kind of sulphuric acid, and especially separated sludge acid of any quality. The underlying principle of the process is concentration by blowing hot air, at a temperature of about 1,200 deg. F., through the acid. The process is continuous except that when handling sludge acid the concentration must be carried out in two stages for reasons stated later.

Operation of Submergence System on Sludge Acid

In concentrating sludge acid from oil refineries, the operation is carried out in two stages in order to avoid frothing and foaming due to the decomposition of the hydrocarbons. In the first stage operation the weak acid is fed in at the top of the tower direct from the pumping lines. The pumping and regulation of the acid are done entirely with the well-known acid air lifts. The rate of supply is carefully regulated to control the speed of operation, also the strength and temperature of the acid bath in the concentrator. By controlling the temperature and the quantity of air blown through the acid and the amount of acid fed to the concentrator, the acid in the pan is maintained constantly at from 50 to 55 deg. Bé., or just below the point at which foaming commences. At this strength the acid hydrocarbons are broken down and volatilized by the rapid stream of air passing through the acid. The acid remains constantly at a strength sufficiently low so that carbonaceous matters (tar, oil, etc.,) are not attacked, and consequently the losses in the first unit are practically negligible. The acid is drained off continuously, passing through a cooler into intermediate storage tanks, from which it is pumped to the top of the high stage unit for the second stage operation. The operation of the high stage unit is very similar to that of the low stage unit. The acid bath is maintained at 66 deg. Bé. and is drawn off continuously at that strength. The finished acid comes out of the concentrator at about 110 deg. F. below its actual boiling point.

Each unit is provided with a tower packed with checkered brick which serves principally as a preheater.

The hot air is produced by the combustion of oil in a specially designed combustion furnace which operates under pressure. A blower provides air sufficient for combustion and an excess necessary for the proper regulation of the temperature. The hot air from the combustion chamber passes through a main header to both units and is distributed through manifolds to a point below the acid level in the concentrator bath.

When the air at 1,200 deg. F. is released under the surface of the acid, it quickly gives up its heat and passes out of the bath at a temperature slightly higher than the temperature of the acid. It gives up most of its remaining heat in passing through the preheating tower.

The two units in which the first and second stages of concentration are carried out are of similar construction. The acid bath is contained in a rectangular

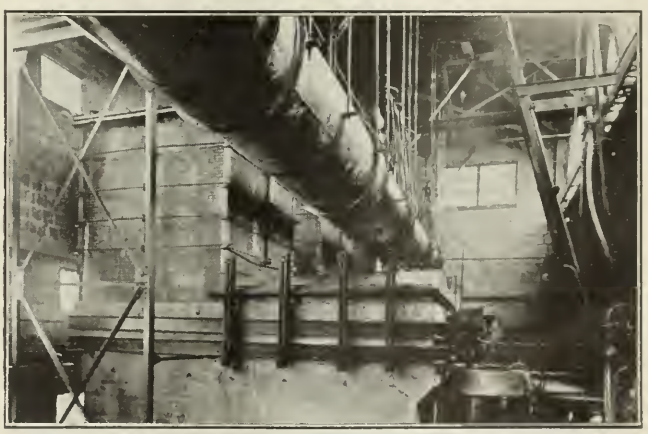

FIG. 3—SEPARATED SLUDGE ACID CONCENTRATING PLANT IN OPERATION

lead pan on a raised concrete foundation, the pan being lined with acidproof brick. About two-thirds of the pan is covered with a chemical brick arch, through which project the acidproof iron pipes that carry the hot air under the surface of the acid. A tower of acidproof masonry rises from the rear end of the pan to a height of about 30 ft. This tower is packed with staggered brick and provides sufficient surface for the transfer of the heat from the escaping gases to the incoming acid.

The results over a protracted period of operation

have shown the oil consumption to be around 35 gal. per ton of 66 deg. Bé. acid when starting from acid of 35 deg. Bé. at room temperature. This oil consumption figure includes raising the heat of the acid in the second stage operation. This gives an equivalent of about 9½ to 10 gal. of oil per ton of 66 deg. Bé. acid when starting from 60 deg. Bé. In the lead pan system, besides the expense incurred by frequent repairs to the pans, it has been recorded that it requires 90 to 110 gal. of fuel to concentrate 1 ton of 66 deg. acid when starting from 35 deg. Bé.

One man per shift can operate the largest plant in existence, and the maintenance cost has proved to be around 30c. per ton of 66 deg. acid.

Comparative cost of concentrating sludge acid by the old and new method is as follows:

Cost of Producing 66 Deg. Acid From 35 Deg. Bé. Sludge Acid Using Lead Pans and C. I. Stills

100 gal. oil at 4c.	$4.00
Labor	.60
General expenses and repairs	2.50
Losses, 20 per cent based on $8 per ton of 60 deg. acid	1.60
Operating cost per ton 66 deg. acid from 35 deg. Bé.	$8.70

Cost of Producing 66 Deg. Acid From 35 Deg. Bé. Sludge Acid Using Hot Air Submergence Type

35 gal. oil at 4c.	$1.40
Labor	.20
General expenses and repairs	1.10
Losses, 6 per cent based on $8.00 per ton 60 deg. acid	.48
Royalty	1.00
Operating cost per ton 66 deg. acid from 35 deg. Bé.	$4.18

Sulphuric Acid Gas Recovery

The method of recovering gases has not been touched upon. This is interesting, because the fume trouble has always been an important subject for lawsuits.

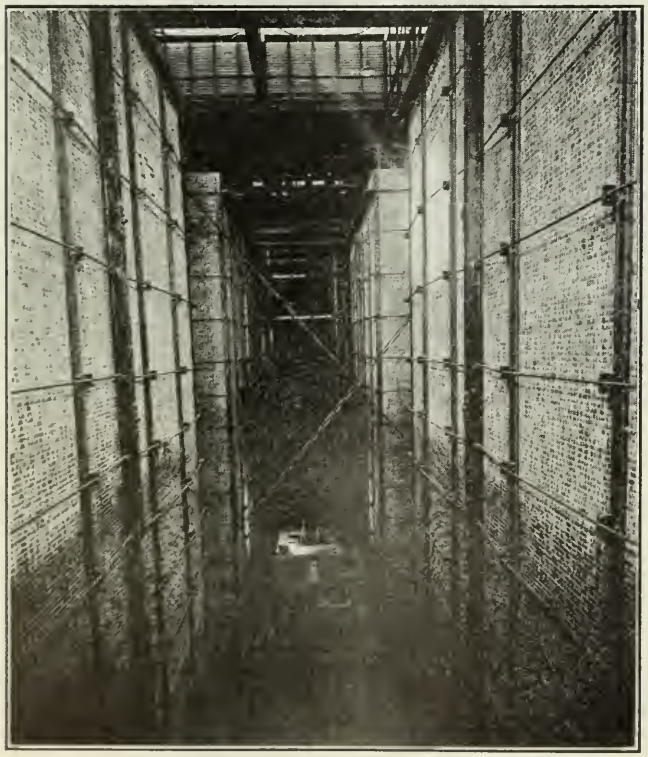

FIG. 4—NITRIC ACID ABSORPTION TOWERS AT U. S. NITRATE PLANT NO. 2

In the indirect method of concentration, the escaping gases may be efficiently condensed in water-cooled condensers, but when concentrating by the direct heat method, the escaping gases are of greater volume, for which reason such condensers are impracticable. In general practice a filtering or scrubbing tower is used. These generally consist of towers or large boxes constructed of lead or acidproof masonry, packed with suitable tower filling, such as coke, hard coal, quartz or rings. If the filtering area, or the tower filling, is of large enough volume, and if the filling material itself is efficient, water is not required. In cases where the filtering area is small, the gases will be absorbed more efficiently by spraying a little water in at the top of the tower. When using water for filtering, in some cases the strength of the distillate acid varies from 30 to 40 deg. Bé. In efficient towers the condensed acid varies in strength from 40 to 55 deg. Bé. when no water is used.

The electric precipitator is being used exclusively for the precipitation of the acid gases in conjunction with hot air submergence type concentrators, whether used for concentrating chamber acid, sludge acid or other contaminated acids. It has also been found very effective on other installations. It looks as if this precipitator will eventually replace all other gas-filtering methods, as the construction is very simple, the recovery the most perfect and the cost of operation very little. The acid comes out of the precipitator at from 50 to 60 deg. strength and the recovery in several instances has been recorded at 99 per cent, while the recovery in filtering towers varies from 60 per cent to 95 per cent.

Acidproof Masonry

The use of acidproof masonry as a permanent construction material for concentrators has been mentioned several times. The success of this construction for concentrators and for all other kinds of acid absorption and treating towers is assured. The construction requires careful design, the use of superior and proper grades of material, the best workmanship and the proper curing and treating of the cement, especially in the hot towers for sulphuric acid. The outer walls are constructed of acidproof shale brick and acidproof cement, and the inside of tower is lined with several layers of 1-in. chemical tile. Towers thus constructed are very durable and if the work is properly done and the towers properly treated, very little seepage will take place. All masonry towers should be operated under slight vacuum.

Several makes of cement have been used—for example, "Acipruf" as manufactured by the Chemical Construction Co., and "Duro" as used by the Process Engineering Co. In these cements, sodium silicate is used as a binder.

The largest example of acidproof masonry work in this country is the installation of the nitric-acid absorption towers and acid concentrators at government nitrate plants at Sheffield and Muscle Shoals. In both places combined there were fourteen large towers, each measuring 32 ft. square on the outside and 60 ft. high, each tower being divided into four parts and each part packed in its entirety with "Chemico" spiral packing rings. In these installations it required millions of brick and several thousand tons of "Acipruf" cement. During the operating test period of these towers, no leakage whatever developed.

Preparation of Metal for Microscopic Examination

From Laboratory Notes by
William Campbell
Professor of Metallurgy, Columbia University

Preparation of Specimens

FOR microscopic examination it is necessary to have a flat surface free from all scratches and possessing a high degree of polish. To attain this, various methods may be followed, depending on the nature of the specimen and the polishing equipment available.

For ordinary material, the most convenient size of specimen is from ½ to 1 in. square and ¼ to ⅜ in. thick. Larger specimens are increasingly difficult to handle.

Brittle and hard material may be broken with a hammer or cut with an emery disk well flooded with water to prevent heating. It is then ground down flat on an emery wheel of No. 60 grade or slightly coarser. Extremely brittle material will not stand the emery wheel and has to be taken down on a lap or a flat glass plate using carborundum powder of about FFF grade.

Normally tough material is cut to size with a power hacksaw. A flat surface is then obtained by using "smooth" and "dead smooth" files, rubbing the specimen on the file, which is held on the jaws of a vise. Steel and cast iron may be ground free from hacksaw marks on the emery wheels.

Material of small size has to be mounted. For wire or sheet a convenient method is to hold the specimen in a clamp built up of two brass plates, 1 in. x ½ in. and ⅜ in. thick, held together by two screws. A layer of red fiberboard or Bakelite is placed between the brass plates and the specimen. For thin wires, a mount can be made of fusible metal or "gum-lac," set in a brass container.

Having obtained a smooth surface of workable size, the next step is to get as fine a surface as possible preliminary to the final polishing with rouge or alumina. With mechanical polishing this can be done on finer grades of emery wheels (No. 100 and 200), or disks covered with strong, fine canvas and armed with carborundum or alundum powders of progressively finer grades. The number of grades necessary depend on the nature of the specimen. Disks should run horizontally.

With hand polishing the specimen is rubbed on the following grades of emery paper:

1. Rough—Commercial No. 0
2. Smooth—Commercial No. 00
3. French—Hubert No. 0
4. French—Hubert No. 00
5. French—Hubert No. 000

The specimen is first rubbed on the rough paper perpendicular to the direction of the file marks or emery wheel scratches until all of these have disappeared. The specimen is then dusted and wiped free from all grit and rubbed on the smooth paper, the new scratches being 90 deg. to those of the last paper, and so on through the series. All scratches from the previous paper must be taken out before passing to the next. Grits from one paper must never get onto the next, or the specimen will be spoiled.

Final polish is given with well-washed rouge or alumina. With hand polishing a block of wood, 12 x 6 in., is covered with broadcloth stretched tight. It is covered with well-moistened rouge or alumina, conveniently kept in a wash bottle containing 1 part rouge to about 5 parts of water. The specimen is given a circular motion to avoid pitting. When mechanical polishing is used, the disk is covered with broadcloth and armed with rouge or alumina as above, and runs horizontally at not over 500 r.p.m. If a higher speed is used, the polishing material is thrown off the wheel unnecessarily. If the disk revolves vertically, much polishing material is thrown off even at lower speed. In all this kind of polishing the specimens must be revolved round and round the wheel or pitting results, due to a scouring action in the softer spots.

The above methods hold good for iron, steel, cast iron, brass, bronze, or bearing metals. However, very soft alloys, such as the solders or any alloy with a large porportion of lead, must be polished with great care, or the surface of the metal actually flows like molasses, and the true structure is masked. The later etching does not serve to get rid of this difficulty.

When the final polish is finished, wash well under the tap, dry with alcohol and mop or pat the surface with a soft rag. This must be done immediately, or the specimen will oxidize. Do not rub the specimen in any way, or the surface is likely to be spoiled.

Now examine the specimen under the microscope and note any colored constituents, such as slag in wrought iron, oxide, manganese sulphide and silicate in steel, graphite in cast iron, temper carbon in malleable cast iron; oxides or sulphides in copper and its alloys, and so forth. Flaws and cracks in faulty material are to be noted. Shrinkage cavities show up.

In the preparation of specimens the object is to learn the true structure of the material. In many cases this varies with the location of the specimen. In cast material, sections should be cut perpendicular to the cooling surface, from the outside to the center of the ingot or casting. In rolled or forged material the sections should be parallel to the direction of rolling or forging, for a cross-section alone is often misleading.

Development of Structure

The usual method is by etching. Care must be taken to avoid overetching or the specimen must be repolished. The etching material varies with the specimen, as follows:

Wrought Iron. Etch with 5 per cent picric acid in alcohol. The surface of the specimen is covered with the solution on a container, which is rocked slightly to get uniform action. When the picric acid has become very dark, say after 1 minute, the specimen is washed under the tap, and dried with alcohol. This will show up any pearlite present. In order to develop the grains of the ferrite, the specimen is re-etched by immersing in picric acid for 5 minutes. This can also be done by etching in 2 per cent solution of nitric acid in water for 5 seconds, but the picric acid is safer, since there is not the same liability to overetch. Furthermore, nitric acid eats into the iron very deeply around the slag areas and also pits very deeply.

Steel. Etch with picric acid, as above. Pearlite is attacked and turns brown to blue-black. Ferrite and cementite are not attacked. Steels with carbon content in the neighborhood of the eutectoid (0.9 per cent C), possess a structure in which it is often difficult to distinguish between ferrite and cementite when the excess constituent occurs in very thin envelopes. They may easily be distinguished by boiling in a solution of picrate of soda which turns Fe_3C black, but leaves ferrite bright white. The carbon content of pearlite varies

with the rate of cooling and the percentage of manganese present. In ordinary rolled material (bessemer or open hearth) we can assume:

0 to 10 per cent	pearlite.	C in pearlite	= 0.9 per cent
10 to 25 per cent	"	" " "	= 0.85 per cent
33 per cent	"	" " "	= 0.80 per cent
50 per cent	"	" " "	= 0.75 per cent
66 per cent	"	" " "	= 0.70 per cent
75 per cent	"	" " "	= 0.65 per cent
90 to 100 per cent	"	" " "	= 0.60 per cent

With very thin sections, containing from 90 to 100 per cent pearlite and analyzing 1 per cent manganese, the carbon content of pearlite is nearer 0.55 per cent than 0.60 per cent.

Cast Irons. Etch with picric acid. Cementite is likely to be stained before all of the pearlite is developed in certain high-silicon irons showing the "cementite" eutectic as a network more or less discontinuous, surrounding grains containing ferrite, etc. A light etch with 2 per cent nitric acid will often differentiate between the ferrite high in silicon (silico-ferrite) and the pearlite, and still leave the cementite eutectic bright.

Copper Alloys. Pure copper, sheet bronze, cast brass, german silver, etc.: Etch with ammonia and peroxide as described for gunmetal. Ferric chloride, ammonium persulphate and 50 per cent nitric acid have been advocated. Nitric acid etches rather deeply for photographic work, but is better for general work than the other two, but less desirable than ammonia and peroxide.

Gunmetal, Bell Metal, Cast Bronze. When these are etched with 50 per cent nitric acid (1 part concentrated acid to 1 part water) the dendritic structure shows up well, but the eutectoid is darkened and its structure obliterated. A much better method is to use 5 c.c. ammonia with a few drops of hydrogen peroxide and apply it by rubbing with a small wad of absorbent cotton until the structure appears quite clear to the eye. Fresh solutions should be made up in a watch glass for each specimen. By this means the copper-rich cores of the dendrites are deeply attacked while the eutectoid remains quite bright. The eutectoid can be made to show up in strong contrast by flooding the etched specimen with Grard's solution[1] until the color begins to change, and then quickly washing off the liquid reagent under the tap.

Sheet Brass. The structure is best developed by using ammonia with a few drops of hydrogen peroxide, as demonstrated by the wonderful photographs of Mathewson, Bassett and their associates.

Monel Metal. As cast, the structure is best developed by a mixture of dilute acetic and nitric acids. The wrought metal when in the annealed condition can also be etched with Grard's solution, which shows up the grains alternately light and dark. When Monel metal is etched with 50 per cent nitric acid it tends to pit badly, these pits starting with tiny dots of oxide as nuclei. The resulting structure is therefore very badly pitted.

Bearing Metals. For white metals in general use 2 per cent HNO_3 in water or alcohol. Great care must be taken not to overetch the specimen, especially those with a zinc base. Those with a lead or tin base are not so easily overetched and, with care, a 10 per cent HNO_3 in water can be used.

[1] Made of 5 g. ferric chloride, 50 c.c. hydrochloric acid and 100 c.c. water.

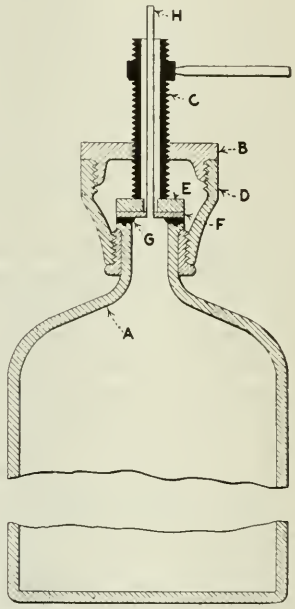
A Simple Type of Glass Pressure Bottle*

By R. R. Reed

Editor's Note—It is not our custom to publish articles dealing with laboratory apparatus, but the possible use of this ingenious device in development work and in tests on manufacturing processes makes it of considerable interest to technical men.

A requisite for every chemical laboratory is a glass pressure bottle, in which reactions between corrosive reagents requiring moderate temperatures and pressures may be carried out. Such a bottle with a capacity of 800 c.c. can be constructed from readily available materials at moderate cost.

The top of a soda-water siphon *A* (the ordinary seltzer bottle) is ground flat on a wet stone and a narrow, shallow groove cut concentrically by means of emery and a metal tube rotated in a lathe, the groove assisting materially in preventing any leakage.



GLASS PRESSURE BOTTLE

The top is constructed of pipe fittings: a reducing coupling *D*; a reducing plug *B*; a short length of ½-in. pipe threaded from the ends so that a T may be screwed down one-third the length of the pipe; an iron disk *E* with a ⅜-in. hole; a lead disk *F*, and an asbestos disk *G*. A very thin platinum foil gasket may be placed between the asbestos and the bottle if necessary.

The top is attached by means of the split, threaded fitting which serves the same purpose in the original bottle. Closing of the bottle is effected by careful application of pressure by means of *C*.

When it is desirable to ascertain the pressure in the bottle, a manometer, made of capillary tubing closed at one end, is attached by means of a ¼-in. copper tube *H*, which extends down through *C*, *E* and *F*, to which latter it is soldered. By this means pressures up to 150 lb. per sq.in. (the limit of safety) may be measured.

Due to the thickness of the glass, heating must be carried out very slowly in a water, salt or oil bath, otherwise breakage is sure to result. In general a rise in temperature to 100 deg. should take about 1 hour. These bottles will stand 150 lb. per sq.in. pressure, but precautions against explosion should always be taken.

Corrosion of Iron and Steel—Influence of Molecular Concentration on Immersion-Test Investigations

Initial Rate of Corrosion the Most Important, Since Solution Rates Change as Equilibrium Approaches —Spent Solutions Often Harmless, but Sometimes Accelerate Corrosion—Short Tests in Circulating Pure Chemicals the Logical Method for Comparative Tests

By D. M. STRICKLAND
Research Engineer, American Rolling Mill Co., Middletown, Ohio

SCIENTIFIC experiments which yield constructive information relative to the various phases of iron and steel corrosion command the attention, not only of investigators, but also of architects, contractors, engineers of tests, civil and highway engineers and all other extensive users of ferrous metals.

Tests in which uncoated sheet metals are exposed to atmospheric conditions yield results which may be of little commercial value, because the conditions of such tests simulate but a limited class of daily service requirements. It is very seldom that uncoated material is chosen for sheet metal installations, the general practice being to protect the sheets with paint, spelter, tin or lead coatings. When uncoated sheets are used for testing purposes the formation of oxide coating introduces into the test a condition not found in actual service. In everyday usage, iron and steels are usually subjected to service requirements far different than the conditions which influence an atmospheric test. This is true for all underground constructions, boilers, tanks, railroad equipment, flumes, culverts and drainage constructions in general. In fact, there are few ferrous metal installations which are not subjected to partial, intermittent or total immersion conditions.

Endeavoring to devise test methods which more nearly approach such conditions of commercial requirements, chemists and metallurgists both at home and abroad have rightly turned to immersion-test investigations in order to obtain reliable data concerning the service life of iron and steel. The supervision of fresh water, salt water and mine water immersion investigations by the American Society for Testing Materials shows that the members of this society recognize the importance of immersion tests.

Laboratory immersion tests when properly conducted are valuable indicators of the performance of ferrous metals, but valuable as such investigations may be, if they are not conducted under conditions of recognized and standardized uniformity, the results are of no value. The importance of uniformity of testing conditions cannot be overestimated, as the non-conclusive and even misleading interpretations which follow an unscientific investigation obscure the solution of any corrosion problem.

The purpose of this paper is to show the reliability of immersion tests when carefully conducted, not only by pointing out the necessity of properly interpreting the influence of solution molecular concentration but also by describing an immersion-test method where the variations in solution strength are reduced to a minimum and one which will be extremely valuable in establishing the immersion test as the most reliable of present day testing procedures.

Immersion tests require close attention and study. Before starting, the investigator must consider carefully the nature of the chemical actions which occur. One must understand not only the influence of temperature changes but also the influence of such variable molecular concentrations as result from unequal evaporation or exhaustion of solution.

Chemical Changes During Corrosion

Corrosion is a chemical change and the reaction conforms to the chemical reaction laws. As the metal reacts with the corroding liquid it is possible that

First, the reaction is irreversible, and an insoluble precipitate forms or a gas is evolved.

Second, a chemical equilibrium is established, characterized by the usual phenomena of the reversible reaction.

Third, byproducts of the reaction in turn attack the metal, inducing a secondary reaction, which in some instances accelerates the corrosion and in other cases retards the primary action.

Usually corrosion reactions are of the first class and irreversible. However, regardless of the type of reaction, at any given moment of time the speed of the chemical action depends directly upon the molecular concentration of the solution surrounding the metal samples. Generally the speed of the reaction approaches zero as the chemical approaches exhaustion or as the pending chemical equilibrium approaches a balance.

It must be remembered that chemical action begins the moment the specimens are brought in contact with the corroding solution. Since the rates of corrosion of the various grades of metals differ, the test conditions quickly lose their uniformity, since the relative resistivity of the metals to the chemical change involved determines the molecular concentration of the solution and this condition governs the reaction speeds.

It is obvious that when this complex variable is considered, true conclusions will be derived from the test data. The various theoretical factors which contribute to variations of molecular concentration may be of little interest to many investigators, but when they realize that such a variable exists and continuously changes the speeds of corrosion even in tests where all other conditions are uniform, their experiments will yield results of great value.

Consider an immersion test where specimens are immersed in equal volumes of a 10 per cent solution of S. An iron or steel reacting rapidly will be surrounded at

the end of T hours by a solution of molecular concentration differing in marked degree from the liquid surrounding test-pieces which reacted at a slower rate. Such a condition usually favors the less resistant metal, as the speed of its corrosion is perceptibly lessened. As the test progresses, some particular grade of material will finally exhaust its solution strength. The action ceases. Unless the solution is then fortified with additional corroding medium or the entire test is discontinued, the iron or steel specimens which have been slightly attacked will continue corroding until in time they catch up with the worst sample. When cleaned and weighed, it will be found that the weight losses are practically equalized and the metal which in reality exhausted its solution first is erroneously deemed to have an equal corrosion-resistance value as metals actually far superior. The following résumé of tests conducted to determine the influence of variable solution strengths are interesting, as they bear out in practice the foregoing statements.

Description of Test Methods

A brief description of test methods will be of interest: Black sheets of 16-gage commercially pure iron made in open-hearth furnaces, coppered iron, common steel and coppered steel[1] were cut into 2x2-in. squares and carefully pickled. They were free from scale, rust, dirt, mechanical injuries, surface irregularities, excessively deep stencil marks, etc. All tests were conducted at room temperature, and any tendency toward unequal evaporation was eliminated. All experiments were run in duplicate and the figures reported are the averages of closely agreeing weight losses. All weighings were checked and the chosen time intervals were accurately followed. The samples were placed vertically in separate tumblers and completely immersed in equal solution volumes.

With such uniform initial conditions, the results obtained in the various corroding media will be influenced by two factors only:

First, the differences existing between the metals under test—that is, their various corrosion resistivities; due in turn to differences in homogeneity, uniformity, chemical purity, surface condition and other factors.

Second, the molecular concentration of the corroding solution.

Loss in Hydrochloric Acid

Test-pieces were immersed in 250 c.c. of 3 per cent hydrochloric acid. One set of samples was weighed at the end of 48 hours; the others remained in the solution for 30 days. Following is a comparison of weight losses expressed in ounces per square foot of actual surface:[2]

Material	End of 48 Hours	End of 30 Days
Commercially pure iron	0.08	4.31
Coppered iron	0.26	4.08
Common steel	0.29	4.20
Coppered steel	0.52	4.13

It would be erroneous to assume from the 30-day data that all metals were equally resistant to the corrosion reaction. The short-time test shows that the commercially pure iron is most resistant to the action of the hydrochloric acid. It is obvious that the various reaction speeds varied as the solution strength weakened. The rapidly corroding coppered steel soon so weakened the acid strength that the action slowed down. Between 48 hours and 30 days the action was so slow that the more resistant metals caught up and yielded equalized weight losses.

In actual service conditions, the corroding medium is generally in excess to the ferrous metals. It is the metal which fails and not the corroding medium which is exhausted. If, in everyday service, metal is in contact with hydrochloric acid, the acid strength would not weaken perceptibly, since it doubtless would circulate. The more rapidly dissolving metal has no opportunity to weaken the corroding medium or slow down in action. Instead, it will continue its rapid corrosion and fail quickly. Thus it is that a short-time immersion test closely approximates the working conditions.

Other samples were immersed in 300 c.c. of concentrated hydrochloric acid (38 per cent). At intervals of 30 minutes the samples were removed, dried, weighed and again immersed in *fresh* acid. Weight losses were determined from time to time with results as shown in Table I.

TABLE I—REPEATED IMMERSIONS IN FRESH CONCENTRATED HCl

Material	End of 5 ½-Hr. Periods	End of 15 ½-Hr. Periods	End of 20 ½-Hr. Periods	End of 30 ½-Hr. Periods
Commercially pure iron	0.14	0.50	0.66	0.75
Coppered iron	0.74	2.62	3.56	5.63
Common steel	1.65	5.25	6.93	10.29
Coppered steel	1.08	3.68	4.28	7.21

These figures verify results obtained by Dr. A. S. Cushman[3] as embodied in his paper wherein he describes the action of 38 per cent hydrochloric acid on pickled galvanized 2x3-in., 26-gage specimens.

TABLE II—REPEATED IMMERSIONS IN FRESH 20 PER CENT HC

Material	End of 5 1-Hr. Periods	End of 10 1-Hr. Periods	End of 20 1-Hr. Periods
Commercially pure iron	0.02	0.05	0.08
Coppered iron	0.03	0.08	0.12
Common steel	0.15	0.31	0.44
Coppered steel	0.04	0.10	0.17

Again, using 20 per cent hydrochloric acid solution and immersing samples in fresh solution every hour, the losses in weight obtained, expressed in ounces per square foot actual surface, are given in Table II.

Loss in Sulphuric Acid

Similar test-pieces were subjected to the action of 200 c.c. of 5 per cent sulphuric acid. The samples were removed from time to time, weighed and re-immersed in the same acid. The results are given in Table III.

TABLE III—REPEATED IMMERSIONS IN THE SAME 5 PER CENT H_2SO_4

Material	24 Hr.	48 Hr.	192 Hr.	40 Days
Commercially pure iron	0.09	0.16	0.93	4.25
Coppered iron	0.02	0.08	0.17	4.18
Common steel	0.28	0.38	1.77	4.20
Coppered steel	0.07	0.15	0.42	4.15

These results again show that if the test is undisturbed for a sufficient length of time the weight loss will

[1] Average analyses of the various materials:

Material	S	P	C	Mn	Cu
Commercially pure iron	0.020	0.005	0.010	0.009	0.020
Coppered iron	0.028	0.006	0.010	0.015	0.204
Common steel	0.020	0.012	0.090	0.273	0.034
Coppered steel	0.025	0.011	0.110	0.420	0.235

[2] All weight losses are reported as ounces per square foot actual surface. To convert to grams per square meter actual surface, multiply the reported figures by 305. A piece of 16-gage, having one square meter actual surface, weights 6,100 grams; one square foot weighs 20 ounces.

[3] "Notes on Some Anomalies Encountered in a Study of Immersion Tests of Iron and Steel," by A. S. Cushman and G. W. Coggeshall, American Electrochemical Society, 1921.

approach equality. The weight loss of each grade increases with time until the strength of the solution is weakened to such an extent that the speed of corrosion diminishes. For example, at the end of 192 hours the common steel lost 1.77 oz. per sq. ft., whereas at the end of 40 days this metal (instead of corroding at the same rate for a total loss of 8.85 oz. per square foot) had lost only 4.20 due to the fact that a weakening solution had retarded the corrosion reaction.

Loss in Nitric Acid

Using a 5-hour time interval between solution changes, similar test-pieces were immersed in 300 c.c. of concentrated nitric acid (70 per cent), with results as shown in Table IV.

TABLE IV—REIMMERSED IN FRESH 70 PER CENT HNO_3 EVERY 5 HOURS

Material	End of Total Immersion of 120 Hr.	End of Total Immersion of 240 Hr.
Commercially pure iron	0.09	0.17
Coppered iron	0.70	1.42
Common steel	0.23	0.48
Coppered steel	0.21	0.46

Had this test continued to the exhaustion of the reacting metals or corroding medium, figures would have been obtained which would be without value. This test is all the more interesting in that iron and steel is generally understood to be passive when in contact with cold concentrated nitric acid, whereas in this instance sufficient weight losses were obtained in 10 days to indicate accurately the greater resistivity of the commercially pure iron.

Loss in Aluminum Sulphate

Two separate tests were conducted in beakers containing 250 c.c. of 20 per cent anhydrous aluminum sulphate. One was permitted to continue until all specimens had exhausted their solutions. It required 1,500 hours for the commercially pure iron to reach this point, at which time the test was discontinued. Test-pieces used in the second test were all removed from the liquid after 296 hours when the most corodible metal had exhausted its solution. Table V shows the results.

TABLE V—CORROSION IN ALUMINUM SULPHATE

Material	End of 1,500 Hr.	End of 296 Hr.
Commercially pure iron	6.73	0.066
Coppered iron	6.80	0.138
Common steel	7.00	1.106
Coppered steel	7.00	5.113

It would be unjust to assume anything from the results obtained in 1,500 hours. The short-time tests shows that the coppered steel lost eighty times as much metal as did the commercially pure iron. This test is interesting in that it gives a striking example of relative initial resistivity.

Although it requires increased attention, investigators who remove all the samples at regular time intervals and again immerse them in full-strength solutions are conducting their tests in a manner closely approximating usual commercial requirements. As a rule, the shorter the time interval between solution changes the nearer will test conditions approach actual service conditions where the corroding medium is changing continuously. It would be poor practice to fortify from time to time all the solutions by adding equal volumes of the corroding medium. This would increase the complexity rather than simplify the problem of solution changes, as such practice would certainly concentrate solutions to variable extents, depending upon the relative amount of depletion occurring up to that time.

Loss in Ferric Chloride

In this experiment several groups of samples were immersed in 200 c.c. of 3 per cent ferric chloride and permitted to remain for various periods of time. At the end of each time interval the corroding medium was discarded and, after cleaning and weighing, the test-pieces were immersed in freshly prepared 3 per cent ferric chloride. The results, expressed in loss of weight in ounces per square foot of actual surface are summarized in Table VI.

TABLE VI—CORROSION BY PERIODICALLY RENEWED FERRIC CHLORIDE (3 PER CENT)

24-Hour Periods

Material	First 24 Hr.	Second 24 Hr.	Total 48 Hr.	Third 24 Hr.	Total 72 Hr.	Fourth 24 Hr.	Total 96 Hr.
Commercially pure iron	0.22	0.29	0.51	0.31	0.82	0.29	1.11
Coppered iron	0.24	0.30	0.54	0.33	0.87	0.31	1.18
Common steel	0.27	0.30	0.57	0.32	0.89	0.30	1.19
Coppered steel	0.27	0.32	0.59	0.33	0.92	0.31	1.23

48-Hour Periods

Material	First 48 Hr.	Second 48 Hr.	Total 96 Hr.
Commercially pure iron	0.36	0.35	0.71
Coppered iron	0.37	0.35	0.72
Common steel	0.37	0.35	0.72
Coppered steel	0.39	0.37	0.78

96-Hour Periods

Material	First 96 Hr.	Second 96 Hr.	Total 192 Hr.
Commercially pure iron	0.39	0.43	0.82
Coppered iron	0.41	0.43	0.84
Common steel	0.41	0.45	0.86
Coppered steel	0.40	0.55	0.95

192 Hour-Periods

Material	First 192 Hr.
Commercially pure iron	0.38
Coppered iron	0.42
Common steel	0.43
Coppered steel	0.57

240-Hour Periods

Material	First 240-Hr.	Second 240 Hr.	Total 480 Hr.
Commercially pure iron	0.47	0.38	0.85
Coppered iron	0.51	0.45	0.96
Common steel	0.49	0.36	0.85
Coppered steel	0.48	0.48	0.96

Table VI shows clearly how weight losses are absolutely dependent on the solution strength. The weight losses for each 24-hour interval agree closely. Even though the weight loss for a single 48-hour period is approximately 20 per cent greater than for a 24-hour period, yet the significant fact remains that the losses at the end of two 48-hour periods are much less than the weight losses recorded for three 24-hour periods. In fact, at the completion of four 24-hour periods figures were obtained which were greater than those recorded for any other time interval or combination of time intervals, including the two 10-day periods.

Investigators should determine before starting their immersion tests what time intervals should elapse between solution changes. Differences in losses between samples immersed for variable time periods will be noticeable regardless of the time intervals chosen, providing the shortest interval is not longer than the time required for equalization. Notice the ferric chloride weight losses for the 192-hour and 240-hour periods. Here we have average losses of 0.45 and 0.49 oz. per square foot, showing that these time periods are both too long to be used if reliable data are desired. It is probable that at the end of 96 hours an even greater variation in total corrosion would have resulted had 12-hour instead of 24-hour periods been used.

It will be noted that the various experiments described in this paper have corrosion reactions which are so rapid that it is only necessary for a few hours to elapse before confirming evidence is obtained showing that molecular concentration is an important variable in immersion tests. Although it would require many months to duplicate the evidence for slow reactions, nevertheless similar data would be the result of the longer investigation. This is because corrosion is a chemical change and the reactions involved conform to reaction laws. Consequently, if the corroding medium plays a direct part (no matter how slight or slow reacting), it must follow that the molecular concentration changes and reaction speeds vary, even though long periods of time may elapse before the influence is detectible.

It is possible that the corroding medium exerts only an indirect influence. The character of the reaction may be such that as the chemical in solution reacts with the ferrous metals the byproducts interact to the replenishment of this chemical. The solution may act as a catalytic agent, a carrier of necessary oxygen, an intensifier of electrolytic action, or in some other capacity where the corroding medium is seemingly unchanged. An investigator will study such complex reactions and use all the greater care to insure uniform test conditions. Unequal evaporation or water additions give a conductivity variable to electrolytes; variable air supply changes uniformity in tests requiring oxygen. There are a multitude of factors which influence tests where the functions of the corroding media are indirect; conclusions drawn from such investigations will indeed be valuable when due care is given to these variables.

Loss in Ammonium Persulphate

The solution used in this experiment was 10 per cent crystalline ammonium persulphate and it was conducted in the same manner as described immediately above for ferric chloride. See Table VII.

It is apparent that the figures in Table VII are comparable with results reported for the ferric chloride tests. After the samples had been immersed for four 24-hour periods, the resulting losses are again far greater than any other figures obtained. The losses after a 50-day immersion period were less than for two 24-hour intervals. It is conservative to say that during the 50-day period all samples lay idle in an exhausted solution for about 45 days.

TABLE VII—CORROSION BY PERIODICALLY RENEWED AMMONIUM PERSULPHATE (10 PER CENT)

24-Hour Periods

Material	First 24 Hr.	Sec. 24 Hr.	Total 48 Hr.	Third 24 Hr.	Total 72 Hr.	Fourth 24 Hr.	Total 96 Hr.

48-Hour Periods

Material	First 48 Hr.	Second 48 Hr.	Total 96 Hr.
Commercially pure iron	2.42	2.22	4.64
Coppered iron	2.96	2.88	5.84
Common steel	2.81	2.66	5.47
Coppered steel	3.72	3.43	7.15

96-Hour Periods

Material	First 96 Hr.	Second 96 Hr.	Total 192 Hr.
Commercially pure iron	2.98	2.67	5.65
Coppered iron	2.99	3.34	6.33
Common steel	3.05	2.96	6.01
Coppered steel	3.50	3.51	7.01

50-Day Period

Material	End of 50 Days
Commercially pure iron	3.52
Coppered iron	3.82
Common steel	3.62
Coppered steel	3.96

Considering the 50-day test alone, it would appear that the coppered steel lost approximately 12 per cent more than the commercially pure iron samples, whereas the decisive short-time tests indicated that this percentage should be 39. Had 12-hour or 6-hour periods been used for the shortest time interval this percentage would no doubt be greater. In fact, as the interval between solution changes shorten, the weight losses obtained approach the true figures to be expected from actual service.

This series of experiments shows very clearly that valuable conclusions may be drawn from rapid tests conducted under proper conditions. Conclusions which have been derived from tests conducted in the past are open to question unless such tests were scientifically controlled, with due attention given to the variable molecular concentration of the various corroding media.

Recommended Procedure

The most successful means of conducting immersion tests, yet a procedure which will closely approach actual service conditions, is to immerse all test-pieces in one tank. The specimens should be suspended on glass rods

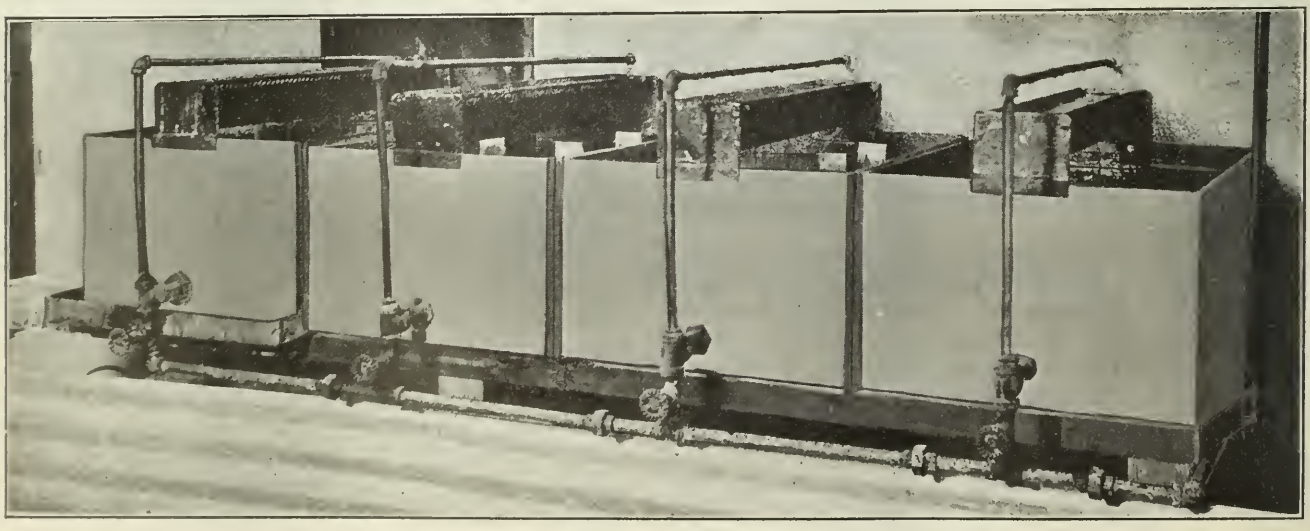

FIG. 1—ROW OF TANKS FOR CORROSION EXPERIMENTS

at distances apart sufficient to prevent any tendency toward electrolytic action. The tank should be ample in size to hold a large volume of the corroding liquid, so that when possible, the reacting chemical will be present in amounts in excess to the ferrous metals. Fig. 1 shows equipment adaptable for these suggestion.[4]

Although this illustration shows a metal tank, stoneware or enameled ware can be used equally as well. A convenient size is 12x18x30 in. An air lift is employed for circulating the solution. Air regulated by the globe valve and blowing up the vertical pipe from the bottom of the tank requires but a small amount of air to lift the solution from the bottom of the tank to a pipe parallel to and above the V-shaped trough which is placed between the pipe and the surface of the liquid. The solution will not only mix with air while passing through the pipes but will also have the opportunity to absorb additional air when dripping from the holes in the pipe into the trough and from the trough into the liquid in the main tank. Evaporation losses are equalized and temperature conditions are uniform when tests are conducted under the conditions described. Although the molecular concentration of the solution may vary continuously, yet at any moment of time the same strength of solution is attacking all grades of material under test. In investigations where the solution strength changes rapidly, it is possible to determine accurately this variable by daily tests and to fortify the liquid by calculated additions. If the reaction by-products form in appreciable amounts and exert either an accelerating or retarding influence, the entire solution can be easily changed.

Mercury Poisoning

There is probably no industry, trade or art in which mercury is used which has not produced some cases of mercury poisoning. In the mining and smelting of mercury the hazard has long been recognized.

The cases of industrial mercury poisoning occurring about mines and reduction works are usually chronic in form, with occasional development of acute symptoms when the workmen are exposed to undue amounts of mercury vapors, dust, or soot. The cardinal symptoms of the disease are stomatitis (inflammation of the mouth), often with some salivation, tremors and a peculiar timidity (erethism). These symptoms are accompanied by organic degenerative changes in various organs of the digestive system, circulatory system and the kidneys. Insufficient or improper ventilation of the working places, together with failure to maintain sufficient back pressure to prevent the escape of mercury vapor from furnaces, condensers and retorts, is a very important predisposing cause of the poisoning. Uncleanliness of the workmen appears to be no small factor in the production of the condition. Men who do not wash their hands well before eating or putting anything into the mouth, who do not care for their teeth and who fail to rinse the mouth well before eating and drinking, those who do not take a hot cleansing bath at the end of each day's work and who do not change their work clothing for street clothing after work develop poisoning more often than those taking these precautions.

Further details are given in Serial 2,354, just issued by the Bureau of Mines.

[4]This equipment was first described in "Observations on the Corrosion of Iron and Steel," by J. A. Aupperle and D. M. Strickland, American Electrochemical Society, 1921.

Plant Transportation, Plant Roadways and Concrete

By Graham L. Montgomery

OTHER things besides the selection of the correct machinery and appliances must be considered when purchasing the equipment for a plant transportation system. It is important to be able to form some opinion in advance as to just what effect the equipment will have on plant conditions other than material handling. It is important to determine the proper relations between the new equipment and the existing plant so that any changes that are necessary to enable the new equipment to function at its best may be made. It is often found necessary to make such changes, even when by so doing some interference occurs with other phases of the operation so as to reduce their efficiency. On the other hand, these changes often give benefits to some phase of operation other than transportation which had not been foreseen and which may actually be of as great or greater value than the benefit which the transportation derives. It will be seen, then, that any changes of this nature must be carefully weighed, and such disadvantages as may be foreseen balanced against the advantages that are to be derived, before a sound decision can be reached as to the course to be followed.

Plant Transportation

Chemical plants and many other plants of a similar nature often consist of a multiplicity of buildings, distributed over a wide area. Generally each building houses but one or two steps of the process at most, and often, as a result, the different steps are separated by considerable distances. This means that it is necessary to handle a large amount of material between the various buildings, from step to step of the processes. In addition the raw materials must be unloaded and then taken to the storehouse or to the primary step of a manufacturing process and the finished goods must be moved from the last step of manufacturing to the warehouse or shipping department.

This means that some form of mechanical transportation equipment is a necessity in such a plant. Of course, it is always wise for a manufacturer so to equip and organize his plant that costs of production are kept at a minimum. And this is particularly so under present conditions of manufacture, when the labor cost of manufactured goods is disproportionately high and the market conditions make it imperative to produce with the minimum of cost so that the goods may be held at a low enough price to find a ready sale.

Transportation Equipment

The equipment employed to accomplish this transportation will vary with the nature of the goods produced in the plant. In a plant where the goods are all of one class, the solution will rest in choosing the one type of equipment which is best suited to handling goods of this class. Many plants require several different types of equipment, as the handling includes several different classes of material. Thus we find handling equipment comprising traveling cranes, monorail hoists and some form of storage battery trucks in common use by large foundries for the solution of their transportation problems.

The largest category of these plants, however, is that in which the goods to be handled cover a wide variety of

sizes, shapes and weights and the physical constitution of the plant precludes any possibility of an economic utilization of such fixed-path equipment as a crane, monorail or industrial railway. Here the solution most commonly arrived at is to use a fleet of storage battery trucks, or a storage battery tractor or two with a fleet of trailers. The choice between truck and tractor and trailers rests on such factors as length of haul, speed at which it is desired to handle, character of handling and size of plant. In general, the choice falls on the truck when the haul is short, when the goods are light, when speed is desired, or the total to be moved is small, while under reverse circumstances the tractor and trailers get first call.

Plant Roadways

In all plants of the type here under discussion, when the transportation system utilizes trucks or tractors, there must be some sort of roads between the various buildings. It is obvious that the better these roadways are the more successfully the trucks and tractors can be used. The necessity for such roadways has long been a commonplace in a number of industries. In the metal-working industry we have many examples from the small unit made up of perhaps but two buildings with a paved runway between up to such huge units as the plants of the Ford Motor Co. or the General Electric Co., where the plant roadways become veritable speedways.

Unfortunately for the chemical and allied industries, they have not come to as keen a realization of the possibilities pointed out above as have plants in some other lines of industry. In the first place, despite the adverse conditions of labor market and sales market, by far the larger number of such plants have made no endeavor whatever to utilize mechanical handling devices of any kind. Then again, it is quite usual to find the roadways of these plants in a truly deplorable condition—rough, muddy, and, in wet weather, almost impassable.

The Concrete Solution

Apropos of these facts, it is worth while noting what has been done at the Rensselaer plant of the Grasselli Chemical Co. This plant is an ideal example of a plant consisting of numerous buildings and having a transportation problem to be satisfactorily solved only through the use of a tractor and trailers. The mud difficulty must have been particularly pronounced at this plant at one time, as it is on low lying ground, at best but little above normal water level of the Hudson.

In order to get away from this difficulty, concrete roadways have been built throughout the plant. The accompanying illustration shows one of these roads with the tractor and a train of trailers on it. It was stated to the writer that, by the placing of this concrete, which cost but little more than the tractor and trailers, full, continuous and satisfactory plant transportation had been attained. As closely as can be figured, the whole installation must have paid for itself in less than two years.

TRACTOR AND TRAILERS ON CONCRETE ROADWAY, GRASSELLI CHEMICAL CO., RENSSELAER, N. Y.

Now, as to the other influences which the placing of this concrete had on plant conditions: A clean and dry path was provided at all times from building to building. The appearance of the plant was greatly improved. These two things improve both the workers' health and their morale. The reflection of these improvements is apparent throughout the plant in increased efficiency and lowered production costs. It is, however, impossible to separate the exact amount of improvement out into dollars and cents, and so this amount must remain unnamed, although the management states that there is no doubt that it exists.

Conclusions

Although this matter of trucks and good plant roads is a simple one, its importance should not be overlooked. The profits to be realized—directly through the use of proper plant transportation equipment in a proper way and indirectly through generally improved conditions—are well worth attainment by any manufacturer. Just because a thing has not been customary in the past is no reason why it should not, provided it is worth while, become customary in the future. It will be well for the chemical and allied industries for this once to pattern on the metal-working industries, where the great successes of the past two decades have been made possible by the pioneering spirit which adopted new equipment and methods as fast as these could be proved sound.

Comparison of Methods of Cleaning Blast-Furnace Gas*

By N. H. Gellert

THE value of clean blast-furnace gas as against dirty or raw gas for use in blast-furnace stoves or in boilers has been so well demonstrated as to cause the largest and most progressive steel companies to spend millions of dollars to install cleaners.

If the gas issuing from a blast furnace were a small item, overlooking its importance might be permissible, but the facts are these:

1. Forty-eight to 50 per cent of the thermal value of the coke charged into the blast furnace issues from it in the form of latent and sensible heat of combustible gases.

2. Thirty per cent of the gas generated is used for increasing the temperature of the blast.

3. Sixty per cent of the gas is used in boilers or engines for power.

*Abstracted from *Mechanical Engineering*, May, 1922.

* From Olsen's Manual. † Calculated. Columns 2 and 3, values from Liddell's Met. and Chem. Handbook; columns 4, 6, 7, 12, and 13, calculated; column 5, values from Poole's Calorific Power of Fuels; column 8, values from Babcock and Wilcox' Steam; columns 9, 10 and 11, from Pratt's Principles of Combustion

Consider for a moment what clean gas will do for hot stoves. At Duquesne tests were made on hot-stove operations using gas in three different conditions. The results obtained, as given in Table I, are at least interesting.

Dry Versus Wet Cleaning

Now if it is conceded, by force of common practice and such data as can be used for argument, that clean gas is to be preferred above dirty gas in stoves and boilers, there remains but one other question to be answered: Shall gas be cleaned by a wet process or a dry process?

Heat Value of Dry-Cleaned Gas.—Suppose we consider the operation of a 500-ton furnace here in the Birmingham district. If every ton of iron required 2,500 lb. of coke, the total coke tonnage per day will be 625 tons. If we take 48 per cent of this to be in the form of gas, then 301 tons must be used for fuel purposes outside of the furnace. Here is presented a possibility for control that should result in savings.

Now there will be about 170,000 cu.ft. of gas generated per ton of iron made. At a 500-ton furnace this would give 85,000,000 cu.ft. of gas per day, 3,540,000 cu.ft. of gas per hour, or 59,000 cu.ft. per minute, at 29.92 in. of mercury column pressure and 62 deg. F.

Assume the gas has a percentage analysis as follows: CO_2, 12.5; CO, 25.4; H_2, 3.5; N_2, 58.6. Assume also that the temperature of the gas in the mains is 400 deg. F. and the moisture at standard conditions is 35 grains per cu.ft.

The thermal value of the gas depends on (1) its latent heat of combustion and (2) its sensible heat; and if the products of combustion escape at, say, 600 deg. F., there will have to be subtracted from the total heat the sensible heat of the escaping products of combustion.

Latent Heat.—First consider the thermal value of the gas.

Table II, the author believes, is the first published attempt to assemble the data given from a number of sources so as to collect the most probable values of the constants involved. In addition values have been calculated to correspond to a temperature of 62 deg. F., the temperature at which most technical gas calculations are made.

By the aid of this table it now becomes a fairly simple task to develop the latent-heat value of the gas which is being considered.

We have available 59,000 cu.ft. of gas per minute at 62 deg. and 29.92 in. mercury column. Of this amount, 14,986 cu.ft. is carbon monoxide and 2,065 cu.ft. hydrogen. The hydrogen has a total latent-heat value of 676,100 B.t.u. and the carbon monoxide a total latent-heat value of 4,771,100 B.t.u., or for all the combustible elements, a total latent-heat value of 5,447,200 B.t.u. per minute. See Table III.

Since, however, the water vapor formed in the combustion of the hydrogen is not condensed in the products of combustion, the lower heat value, 52,920 B.t.u. per lb., should hold. There must therefore be subtracted the difference between these two values for the total latent heat, or (62,032 — 52,920 =) 9,112 × 10.9 = 99,320.8 B.t.u. must be deducted, making the net value of the latent heat 5,347,900 B.t.u.

TABLE III—LATENT HEAT OF COMBUSTION
(59,000 cu.ft. of blast-furnace gas per min.)

Constituent	Per Cent By Volume	Cu.ft. Per Min.	Weight Per Cu.Ft. at 62 Deg. F., Lb.	Total Wt., Lb.	Latent Heat in B.t.u. Per Cent By Weight	Latent Heat in B.t.u. Per Cu.Ft. at 62 Deg. F.	Latent Heat in B.t.u. Per Lb.	Latent Heat in B.t.u. Total
Carbon dioxide	12.5	7,375	0.1163	838.3	18.6	.....	.....	.....
Carbon monoxide	25.4	14,986	0.0736	1,103.2	24.6	318.2	4,325	4,771,100
Hydrogen	3.5	2,065	0.0053	10.9	0.2	328.0	62,032	676,100
Oxygen	0.0	0,000	0.0841	000	00	.....	.....	.....
Nitrogen	58.6	34,574	0.0737	2,548.3	56.6	.....	.....	.....
Total				4,500.7				5,447,200

Sensible Heat.—To this, however, must be added the value of the sensible heat of the gas. This may be determined from the formulas given in Table IV, which hold true for values of gases up to 2,000 deg. C. (3,600 deg. F.) in temperature.

TABLE IV—THERMAL CAPACITIES OF GASES PER POUND FOR TEMPERATURES UP TO 2,000 DEG. C. (3,600 DEG. F.)*

Gas	Pound-Calories	B.t.u.
Hydrogen	$3.370 + 0.0003t$	$3.370 + 0.00017t$
Nitrogen	$0.2405 + 0.0000214t$	$0.2405 + 0.0000119t$
Oxygen	$0.2104 + 0.0000187t$	$0.2104 + 0.0000104t$
Carbon dioxide	$0.19 + 0.00011t$	$0.19 + 0.00096t$
Carbon monoxide	$0.2405 + 0.0000214t$	$0.2405 + 0.0000119t$
Aqueous vapor	$0.42 + 0.000185t$	$0.42 + 0.000103t$

* Tabulated from data in Richards' Metallurgical Calculations.

We may approach our problem then in one of two ways:

1. We may find the mean specific heat of the gas between the limit $(0 — t_1)$, and also the mean specific

TABLE V—FORMULAS FOR SPECIFIC HEAT

Gas	B.t.u. Per Lb. Per Deg.
Hydrogen	$3.370 + 0.00017t$
Nitrogen and carbon monoxide	$0.2405 + 0.0000119t$
Oxygen	$0.2104 + 0.0000104t$
Aqueous vapor	$0.42 + 0.000103t$
Carbon dioxide	$0.19 + 0.00006t$

heat of the same gas between the limits (0 — t_2). From the total sensible heat found in the first instance we may subtract the total sensible heat in the second leaving us a net result. Or,

2. We may find the mean specific heat between the limits (t_1 — t_2) and use this direct to obtain our net sensible heat.

For ease in calculating specific heats the formulas in Table V may be used.

Take 500 lb. of carbon dioxide at 400 deg. F., to find its net sensible heat value if it enters a boiler when the air temperature is 70 deg. F. by the first method:

Specific heat of CO_2 (0°—400°) = 0.2140
Total sensible heat at 400 deg. F. = 0.2140 × 500 × 400
= 42,800 B.t.u.
Specific heat of CO_2 (0°—62°) = 0.1936
Total sensible heat at 62 deg. F. = 0.1936 × 500 × 62
= 6,002 B.t.u.
Net sensible heat (62°—400°) = 36,798 B.t.u.

Now calculating the specific heat of the gas at 400 deg. F., the following results are obtained:

	Mean Specific Heat in B.t.u. Per Deg. F. Per Lb.
Carbon dioxide	0.2140
Carbon monoxide	0.24526
Hydrogen	3.438
Nitrogen	0.24526
Aqueous vapor	0.4612

Let us see now how the values of the specific heats may be used in our calculations.

TABLE VI—DETERMINATION OF SENSIBLE HEAT OF BLAST-FURNACE GAS AT 400 DEG. F.

Given: 1. Total cu.ft. per min. at 62 deg. F. and 29.92 in. Hg dry basis = 59,000.
2. Moisture per cu.ft. dry basis (35 grains) = 0.005 lb.
3. Temperature of gas = 400 deg. F.
4. Percentage analysis, dry basis: CO_2, 12.50; CO, 25.40; H_2, 3.50; N, 58.60.

Constituent	Per Cent By Vol.	Cu.Ft. At 62 Deg. F.	Wt. Per Cu.Ft. At 62 Deg. F.	Wt., Lb.	Per Cent By Wt.	Specific Heat At 400 Deg. F.	B.t.u. Per Lb. At 400 Deg. F.	Total B.t.u.
CO_2...	12.5	7,375	0.1163	838.3	18.6	0.2140	85.6	71,750

H_2O*...	....	.....	0.005†	295.0	.....	0.4612	184.5	54,430
Total	100.0	59,000		4,795.7	100.0	0.2414§	96.57‖	499,040

* Aqueous vapor.
† Per cubic foot on basis of dry gas.
§ Average calculated value mean specific heat dry blast-furnace gas of above analysis.
‖ Per cubic foot dry gas.

In Table VI we consider the weights of the components of the gas and the sensible heat they possess by reason of their specific heat at 400 deg. F., the temperature at which they are passed through the hot-stove and boiler burners for combustion.

This determination of sensible heat is based on values of specific heats between the limits 0 deg. and 400 deg. F. To get an exact value they should be based on limits: temperature of air and 400 deg. F. Since this temperature varies from day to day and season to season, no data developed would hold exactly true. For purposes of comparison the method of determination used should give just as accurate, if not more accurate, results than a method in which daily temperatures must be estimated.

TABLE VII—SENSIBLE HEAT OF BLAST-FURNACE GAS AT 62 DEG. F.

Constituent	Weight, Lb.	Sp. Ht. At 62 Deg. F.	B.t.u. Per Lb. At 62 Deg. F.	Total B.t.u.
Carbon dioxide.....	838.3	0.1937	12.0	10,100
Carbon monoxide.....	1,103.2	0.2412	14.9	16,460
Hydrogen.....	10.9	3.3805	209.6	2,380
Nitrogen.....	2,548.3	0.2412	14.9	37,970
Aqueous vapor.....	295.0	0.4264	25.4	7,480
Total	4,795.7	0.2505		74,390

Assume, however, that this average temperature is 62 deg. F. We can then compute the total sensible heat at limits 0 deg.—62 deg. F. as in Table VII, and this subtracted from the sensible heat at the limits 0 deg.—400 deg. F. gives:

Sensible heat of gas at 400 deg. F.
= 499,040 — 74,390
= 424,650 B.t.u. per min.

The total heat of the gas at 400 deg F. will therefore be:

(1) Net latent heat of combustion..5,347,900
(2) Sensible heat of gas..... 424,650

Total thermal value.....5,772,550 B.t.u. per min.

Combustion Products

Now in a previous table the most probable values have been used as obtained from a number of sources, while the air and oxygen required were obtained from a source in which air was taken to consist of 23.15 per cent by weight of oxygen and 76.85 per cent of nitrogen. Since, however, our data show oxygen to weigh 0.0841 lb. per cu.ft. at 62 deg. F., while nitrogen weighs 0.0737 lb. per cu.ft. at the same temperature, the proportional parts in a cubic foot of air will be as given in Table VIII.

TABLE VIII—AIR-OXYGEN RATIO

Gas	Per Cent By Weight	Wt. Per Cu.Ft.	Proportionate Volume	Per Cent By Volume	Air-Oxygen By Weight	Ratio By Volume
Oxygen....	23.15	0.0841	275	20.89	1.00	1.00
Nitrogen...	76.85	0.0737	1,043	79.11	3.32	3.79
Air.....	100.00	0.0761	1,318	100.00	4.32	4.79

If, therefore, gas be burned by the combination with air, there will be present in the products of combustion, in addition to the new compounds formed, inert nitrogen amounting to 3.32 times the weight of the oxygen combined with the burning gases.

The combustion products when burning carbon monoxide and hydrogen will be as given in Table IX.

TABLE IX—COMBUSTION DATA

Constituent	Symbol	Air Required Lb. Per Lb.	Cu.Ft. Per Cu.Ft.	Products of Combustion—Lb. Per Lb.—CO_2	H_2O	N_2	Cu.Ft. Per Cu.Ft.—CO_2	H_2O	N_2
Carbon monoxide	CO	2.47	2.391	1.58	....	1.89	1	..	1.891
Hydrogen.....	H_2	34.56	2.391	....	9.00	26.56	..	1	1.891

By developing the calculations further (see Table X) we find that when the gas is burned the total products of combustion are:

Carbon dioxide.....	2,581.3 lb. or 22,361 cu.ft.
Water.....	393.1 lb. or 8,289 cu.ft.
Nitrogen.....	4,922.7 lb. or 66,818 cu.ft.
Total products of combustion...	7,897.1 lb. or 97,468 cu.ft.

Sensible Heat of Combustion Products.—These escaping products of combustion take with them out of the stack and into the air a portion of the heat by virtue of their thermal capacities. To know what heat is available for useful work, the sensible heat of these products must be determined at a temperature of 600 deg. F. Using the formula in Table VI, we are able to obtain the following values bearing on this determination:

	Mean Specific Heat in B.t.u. Per Deg. F. Per Lb.
Carbon dioxide.....	0.2260
Aqueous vapor.....	0.4818
Nitrogen.....	0.24764

At 600 deg. each pound of product will have 600 times

TABLE X—PRODUCTS OF COMBUSTION OF BLAST-FURNACE GAS

the thermal capacity here shown. The full analysis of the total thermal capacity of all the products can then be developed and this total sensible heat calculated to be 1,194,800 B.t.u., as shown in Table XI.

Here we must make the same corrections as made for the sensible heat of the gas. Our sensible-heat calculations for gases between the limits 0 deg. and 62 deg. F. are as given in Table XII and the net sensible heat of the products of combustion will be 1,194,800 — 114,380 = 1,080,420 B.t.u. per min. We then have:

TABLE XI—DETERMINATION OF SENSIBLE HEAT OF PRODUCTS OF COMBUSTION OF HOT GAS AT 600 DEG. F.

Constituent	Per Cent By Vol.*	Per Cent By Wt.*	Cu.Ft. At 62 Deg. F.	Total Weight, Lb.	Specific Heat At 600 Deg. F.	B.t.u. Per Lb. At 600 Deg. F.	Total B.t.u. Sensible Heat

Aqueous vapor	393.1	0.4264	25.4	9,980
Total	7,897.1	0.2341		114,380

Total value of the original gas for both latent and sensible heat	5,772,550 B.t.u.
Net sensible heat of the products of combustion	1,080,420 B.t.u.
Gross available B.t.u.	4,692,130 B.t.u.
Less 10 per cent lost because of original loss in gas	469,213 B.t.u.
Net available B.t.u. per minute	4,222,917 B.t.u.

Available Heat and Flame Temperature in Dry Cleaning

All these figures are based on the assumption that blast-furnace gas is delivered at 400 deg. F. to the burners of the hot stoves and boilers. This is, of course, what a dry-cleaning device would enable the operator to do. If, however, he is forced to clean his gas by a wet process there must necessarily be a reduction in temperature of the ingoing gas. This reduction in temperature, it is true, will reduce the moisture content of gas. Whether this reduction in moisture content is of any considerable value, or whether it can compensate for the losses in heat incident to the cooling of the gas, is something that might well be determined. To arrive at a conclusion approaching a semblance of accuracy, two things must be taken into account:

1. The comparison of the flame temperature of the burning gases.
2. The comparison of net available B.t.u. of the gas.

We have already started our study of the available B.t.u. of hot gas containing 35 grains of moisture per cubic foot at 62 deg. F. and 29.92 in. Hg.

Let us consider for a moment the theoretical flame temperature of this gas.

$$T = \frac{\text{B.t.u. produced}}{W \times S_m}$$

where T = the elevation in temperature;
W = weight of products of combustion, and
S_m = mean specific heat of products between temperature of fuel and air and that of products.

The exact value of S_m cannot be found until the value of T is known. For that reason a trial method of computation must be adopted.

The average temperature of the fuel and air will depend on the temperature at which each was delivered to the point of combustion. The gas was delivered at 400 deg. F.; the air at 62 deg. F., and the temperature of the mixture can be shown to be about 251 deg. This figure is interesting but not necessary to our calculations, as we already have the total thermal value of the gas before burning.

Proceeding now to the determination of flame temperature, let us assume 2,480 deg. F. as the correct value. Then, dividing the B.t.u. produced by the sensible heat per degree at 2,480 deg. F., as given in Table XIII,

$$T = \frac{5,772,500}{2,470} = 2,340$$

It is evident that this is the wrong temperature. Assuming 2,400 deg. as the flame temperature,

$$T = \frac{5,772,500}{2,446} = 2,360$$

Again, taking 2,380 deg.,

$$T = \frac{5,772,500}{2,440} = 2,370$$

For our purposes we may take the halfway point between 2,380 and 2,370, or 2,375 deg. F., as the correct flame temperature. Greater accuracy may of course be obtained by another trial.

TABLE XIII—SENSIBLE HEAT OF PRODUCTS OF COMBUSTION PER DEGREE

Constituent	Total Wt., Lb.	Sp. Ht. At 2,480 Deg. F.	Sensible Heat Per Deg.	Sp.Ht. At 2,400 Deg. F.	Sensible Heat Per Deg.	Sp. Ht. At 2,380 Deg. F.	Sensible Heat Per Deg.
Carbon dioxide	2,581.3	0.3388	875	0.3340	864	0.3328	860
Nitrogen	4,922.7	0.2700	1,330	0.2691	1,320	0.2688	1,320
Aqueous vapor	393.1	0.6754	265	0.6672	262	0.6651	260
Total		0.2138	2,470		2,446		2,440

Available Heat and Flame Temperature in Wet Cleaning

So far there have been determined for the gas which is considered as cleaned by a dry process:

1. A value for the available heat which has been found to be 4,222,917 B.t.u. per min. This is the net value after all losses are accounted for.
2. A value for the flame temperature which is 2,375 deg. F.

We now approach the discussion of these same values when the gas is wet cleaned. In this instance the gas will have the same analysis as before, but its temperature will be 70 deg. F. and its moisture content 7.98 grains per cu.ft. of dry gas at 62 deg. and 29.92 in Hg.

Latent Heat.—Its latent heat will be exactly as before, since the heat values of the combustible constituents of the gas have not changed. This gross latent-heat value was found to be 5,447,290 B.t.u. per min.

From this amount there was subtracted the difference between the gross and net value of the heat generated by the combustion of the hydrogen, since there was no condensation of the moisture in the products of combustion before escaping through the stock. In addition there was deducted a 10 per cent loss in gas itself.

With the deduction for the lower thermal value of hydrogen there was a net latent-heat value left of 5,347,900 B.t.u. This holds true with wet-cleaned gas also.

Sensible Heat.—When we consider the matter of sensible heat, however, we have some differences to take into consideration.

The mean specific heats of the component parts of the gas at 70 deg. F. as calculated by the formulas in Table V are as follows:

Carbon dioxide	0.1942
Carbon monoxide and nitrogen	0.2413
Hydrogen	3.3819
Aqueous vapor	0.4272

With these values and such other data as we have already obtained, we may develop a table similar to Table VII, giving a total of 77,620 B.t.u. per min. for the sensible heat of all the gases. The total heat of the 59,000 cu.ft. of gas per min., therefore, is 5,347,900 + 77,620 = 5,425,520 B.t.u. per minute.

Combustion Products.—Turning to the consideration of the products of combustion of this gas, we find that all the products will be the same excepting the moisture content which will be less by the difference between 295 lb. as found in gas containing 35 grains of moisture per cu.ft. and 67.3 lb. is found in gas containing only 7.98 grains per cu.ft. This difference is 227.7 lb. The products of combustion will therefore be:

Carbon dioxide	2,581.3 lb. or 22,361 cu.ft.
Aqueous vapor	165.4 lb. or 3,480 cu.ft.
Nitrogen	4,922.7 lb. or 66,818 cu.ft.
Total	7,669.4 lb. or 92,659 cu.ft.

These products must be assumed to escape at the same temperature as before in order to get a reasonably accurate comparison. If the stack temperature is 600 deg. F. as before, the specific heats of the products will be the same as before. The total sensible heat of each product will also be the same as before, excepting that of the aqueous vapor. In the previous calculation 393.1 lb. of aqueous vapor had a total sensible heat value of 113,640 B.t.u., or 289.08 B.t.u. per lb. Then 165.4 lb. of aqueous vapor will have a sensible-heat value of 47,814 B.t.u. and the total sensible heat of the combustion products will be: (CO_2, 350,020) + (N_2, 731,320) + (H_2O, 47,220) = 1,128,560 B.t.u. per min. From this total there must be subtracted the heat energy present at 62 deg. F.

This will be the same as before, excepting for the aqueous vapor. In the former case 393.1 lb. aqueous vapor had a heat energy of 9,980 B.t.u. per min. Then 165.4 lb. of aqueous vapor which we have to deal with in this latter case will have a heat energy at 62 deg. F. of 4,190 B.t.u. per min. and the total energy will be: (CO_2, 31,000) + (N_2, 73,400) + (H_2O, 4,190) = 108,590 B.t.u. per min.

The net sensible heat of the products will therefore be 1,128,560 — 108,590 = 1,019,970 B.t.u. per min.

It is now possible to determine our net available heat.

Latent and sensible heat of gas	5,425,520
Less net sensible heat of combustion products	1,019,970
Gross available B.t.u.	4,405,550
Ten per cent gas loss	440,555
Net available B.t.u. per min.	3,964,995

Savings.—We have already found that the net available B.t.u. per min. when burning hot gas with 35 grains of moisture per cu.ft. = 4,222,917, and now we have the net available B.t.u. per min. when burning cold gas with 7.98 grains of moisture per cu.ft. = 3,964,995, giving a difference in favor of hot gas of 257,922 B.t.u. per min. or 371,407,680 B.t.u. per day saving in using hot gas over wet-cleaned gas.

On the basis of 500 tons per day the saving will amount to 371,401,680 ÷ 500 = 742,820 B.t.u. per ton. Now Birmingham coke contains about 14,290 B.t.u. per lb. on a dry basis. This would mean that 742,820 ÷ 14,290 = 52.0 lb. of coke is saved per ton of iron made. It is not unfair to take $6 per ton as the price of coke charged into the furnace. Then the saving in the use of hot gas will be (52 ÷ 2,000) × $6 = $0.156 per ton of iron made for coke alone.

Flame Temperature.—We have now to consider the flame temperature of this wet washed gas and with this consideration we are through with our discussion as to heat values. Let us assume the flame temperature to have a value between 2,000 and 2,400 deg. F. See Table XIV.

TABLE XIV—FLAME-TEMPERATURE CALCULATIONS

Constituent	Total Lb.	Sp. Ht. 2,000 Deg. F.	B.t.u. Per Deg.	Sp. Ht. 2,200 Deg. F	B.t.u. Per Deg.	Sp. Ht. 2,400 Deg. F	B.t.u. Per Deg.	Sp. Ht. 2,380 Deg. F	B.t.u. Per Deg.
Carbon dioxide	2,581.3	0.3100	800	0.3112	805	0.3340	860	0.3328	860
Nitrogen	4,922.7	0.2643	1,300	0.2667	1,315	0.2691	1,320	0.2688	1,320
Aqueous vapor	165.4	0.6260	100	0.6466	105	0.6672	110	0.6651	110
Total			2,200		2,225		2,290		2,290

Dividing 5,425,520 respectively by the values 2,200, 2,225 and 2,290 from that table gives 2,460, 2,450 and 2,370 deg. F., and we may therefore accept the flame temperature at 2,375 deg. F., the mean between 2,370 and 2,380 deg. F.

Curiously enough, the flame temperatures of the dry-cleaned and wet-cleaned gases as discussed thus far are the same. Practical experience bears this out also, as Diehl's observations indicate that during reasonable test periods the combustion chamber temperatures are 2,040 deg. F. on wet-cleaned gas and 2,030 deg. on hot raw gas. If the latter had been cleaned, our calculations show it would have had as high a temperature as wet-cleaned gas.

Our discussion on heat values of gas may therefore be summed up as follows:

1. Dry-cleaned gas at 400 deg. F., even if it contains 35 grains of moisture per cu.ft., has a greater available heat value than wet-cleaned gas at 70 deg. F. and 7.98 grains moisture per cu.ft. This heat is 6.5 per cent greater for the former gas than for the latter. At $6 per ton for coke charged into the furnace it means a saving of $0.156 per ton of iron made, in favor of using hot-cleaned gas.

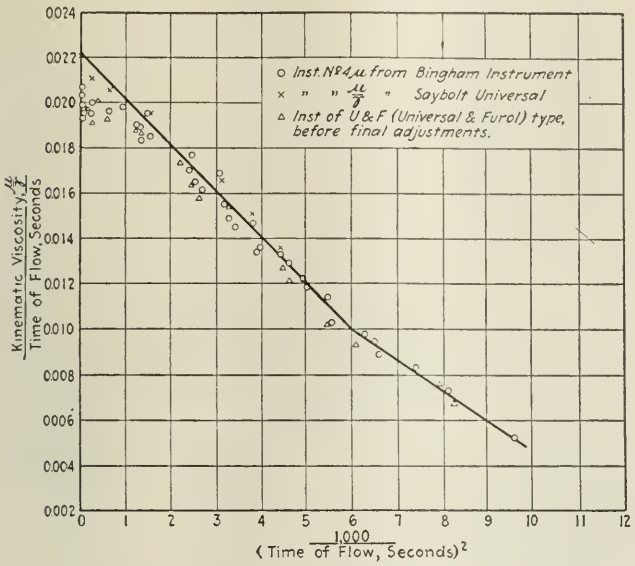
2. There is no difference in flame temperature between the two gases.

Fuel Oil Viscosimeters

By Winslow H. Herschel
Petroleum Technologist, U. S. Bureau of Standards

IT WAS formerly common practice to base fuel-oil specifications upon gravity, but since investigations by the U. S. Bureau of Mines[1] proved that this was not a reliable index of the actual quality of the oil, present government specifications[2] are based upon the viscosity.

The viscosity of fuel oils is often so high that it cannot be measured with the Saybolt Universal viscosimeter or other instruments intended primarily for lubricating oils. The standard instrument for testing fuel oils in England is the Redwood Admiralty or No. 2 viscosimeter, or "viscometer," which is expensive and difficult to obtain in the United States. There appeared, therefore,



o Inst. N°4 μ from Bingham Instrument
× " " $\frac{\mu}{\rho}$ " Saybolt Universal
△ Inst of U&F (Universal & Furol) type, before final adjustments.
Kinematic Viscosity $\frac{\mu}{\rho}$ = Time of Flow, Seconds
$\frac{1,000}{(\text{Time of Flow, Seconds})^2}$

FIG. 1—HIGGINS DIAGRAM FOR SAYBOLT FUROL VISCOSIMETER

to be need of an American-made instrument to serve a similar purpose, and the Saybolt Furol viscosimeter was developed by George M. Saybolt in the spring of 1920 at the suggestion and with the co-operation of the Bureau of Mines.

The following paper will give an account of the standardization and calibration of this new type of viscosimeter as well as the calibration of the Redwood Admiralty type of instrument.

Saybolt Furol Viscosimeter

Saybolt Furol viscosimeter tube No. 4, submitted by George M. Saybolt, was measured at the Bureau of Standards, and on the basis of these measurements the standard dimensions of Table I were suggested to Mr. Saybolt by the bureau and accepted by him. The table also contains the dimensions of tube No. 4.

It will be seen that the standard dimensions are the same as for the Saybolt Universal viscosimeter[3] except d and d_3.

The shorter and larger the diameter of the outlet tube the greater must be the viscosity of the calibrating liquid, and while water could be used for the Ubbelohde

TABLE I—DIMENSIONS OF SAYBOLT FUROL VISCOSIMETERS

Dimension*	Standard — Normal, in Centimeters	Tolerance, in Centimeters	No. 4, in Centimeters
Diameter of outlet tube, d	0 315	±0 002	0 3153
Length of outlet tube, l	1 225	±0 01	1 233
Outer diameter of outlet tube, at lower end, d_3	0 43	±0 03	0 41
Height of overflow rim above bottom of outlet tube, h_1	12 50	±0 1	12 571
Diameter of container, D	2 975	±0 02	2 981
Average head, h (calculated)	7 36	±0 2	7 46

* The normal dimensions are exact figures set up by convention. A dimension may be said to be standard when it comes within the permissible tolerance from the normal.

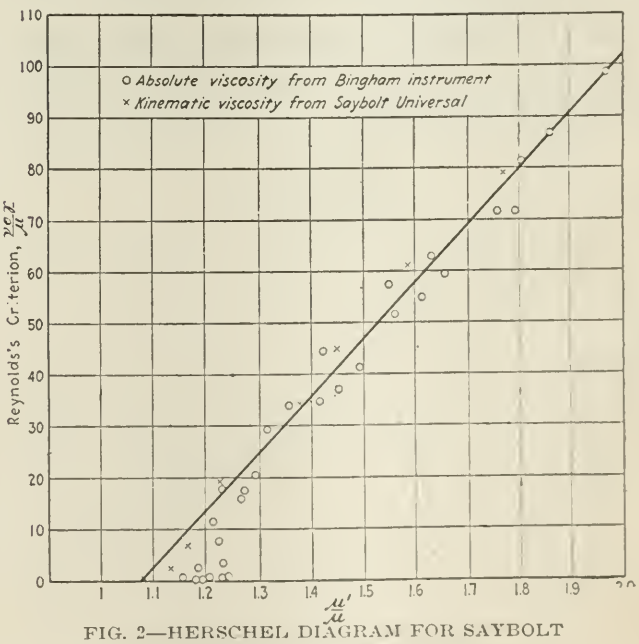
viscosimeter, and ethyl alcohol solutions were made to suffice for the Engler and Saybolt Universal, it was necessary in the present case to use oils whose viscosity had been determined by the Bingham viscometer.[4]

Figs. 1 and 2 show calibration diagrams obtained by the usual methods.[5] Points near the left side of the diagrams are inaccurate on account of the drainage error of the Bingham instrument, and were disregarded in drawing the calibration lines which represent the equation

$$\text{kinematic viscosity} = 0.0222t - \frac{2.02}{t} \qquad (1)$$

The bend in Fig. 1 shows that this equation does not apply when the time of flow is less than 13 seconds or when Reynolds' criterion is greater than 139. It should be noted that the value of Reynolds' criterion at the critical velocity decreases as $\frac{l}{d}$ decreases and that this ratio has a value of only 3.9 for this instrument. Fig. 1 also shows tests with an instrument of the U. & F. (Universal and Furol) type[6], before it had been adjusted to normal dimensions.

Equation 1 does not strictly apply to an instrument of normal dimensions, but such an equation may be obtained by using values of the Couette correction and the coefficient of the kinetic energy correction the same as found from Fig. 2. Thus with the former equal to



o Absolute viscosity from Bingham instrument
× Kinematic viscosity from Saybolt Universal
Reynolds's Criterion, $\frac{vDp}{\mu}$
$\frac{\mu'}{\mu}$

[6] As made by the American Instrument Co., Washington, D. C.

0.311d and the latter equal to 1.128, it may be calculated from the dimensions of Table I that for an instrument of normal or average standard dimensions,

$$\text{kinematic viscosity} = 0.0220t - \frac{2.03}{t} \qquad (2)$$

Redwood Admiralty Viscometer

The Admiralty instrument is described by Redwood as follows:[7]

> The author has devised a modified form of his viscometer, which, with the authority of the Admiralty, will be known as the Admiralty type, for testing oil fuel. This instrument, as its name indicates, has been specially constructed for use in determining the viscosity of oil fuel for contract purposes, and is intended to be employed at a temperature of 32 deg. F. (0 deg. C.). The oil vessel is of the same dimensions as that of the original instrument, but the agate jet is longer and of larger bore, the new viscometer being designed to give an outflow in one-tenth of the time occupied in the outflow of a similar volume from the original pattern. The jet is so mounted as to be surrounded completely by the water in the bath. The water bath, which is of comparatively large size and is jacketed, has no lateral heating tube, but is provided with the usual rotating stirrer. . . . The oil to be tested should be subjected to prolonged cooling at 32 deg. F. by being kept in a refrigerator through the night or for at least 6 hours immediately before being placed in the oil cup, and should be thoroughly stirred before being transferred. When accurate results are desired, the viscometer should be placed in a refrigerating chamber, the temperature of which is maintained at 32 deg. F.

It will be seen that this instrument is inconvenient to operate and entirely unsuited for tests at 122 deg. F. (50 deg. C.), the standard temperature for fuel oils adopted by the American Society for Testing Materials.

Higgins[8] gives equations for the two types of Redwood instrument which indicate that the time ratio is 9.63, while the value indicated by the equations determined at the bureau is 9.20. It would therefore appear that Redwood's value of 10 is only approximate.

Dimensions of two instruments are given in Table II, but no published data have been found to give the standard length and diameter of the outlet tube.

The Bureau of Mines instrument was used in the following tests except in the case of five oils tested by the Standard Oil Company of California on its Redwood Admiralty instrument. The kinematic viscosity of all oils was determined at the Bureau of Standards by the Bingham viscometer.

Figs. 3 and 4 show calibration graphs corresponding to Figs. 1 and 2 for the Furol instrument. They indicate the equation

$$\text{kinematic viscosity} = 0.0239t - \frac{0.403}{t} \qquad (3)$$

and the bend in Fig. 3 locates the critical velocity at which the time of flow is 5 seconds and Reynolds' criterion is 830. This increase in value of Reynolds' criterion, as compared with the Furol instrument, is due to the longer outlet tube of the Admiralty viscometer, which is 13.2 diameters in length.

According to Dean, Furol time equals 1.17 Admiralty time, but he does not show how this value varies with the viscosity. Higgins' equation for the Admiralty instrument, when reduced to c.g.s. units, gives

$$\text{kinematic viscosity} = 0.027t - \frac{12}{t} \qquad (4)$$

while the Kinney Manufacturing Co.[9] give this as

$$\text{kinematic viscosity} = 0.027t - \frac{20}{t} \qquad (5)$$

in accordance with a private communication received from the National Physical Laboratory. It does not seem probable that the difference between these results and equation 3 was due to a difference in dimensions of instruments, and equations 4 and 5 disagree also both with each other and with diagram of McCoull.[10]

150	3.287	9.99	0.921
200	4.390	10.00	0.921

Further doubt is thrown upon equations 4 and 5 by the fact that they cannot be calculated from the dimensions of Table II with any reasonable values of the Couette correction and the coefficient of the kinetic energy correction, for which the values $1.05d$ and 1.123 respectively were obtained and used in calculating equation 3. The large value of $1.05d$, as compared with $0.311d$ for the Furol instrument, may be due to increased surface tension, since the outlet tube of the Admiralty instrument is convex at the bottom and not closely restricted in outer diameter d_3 as is the Furol.

In a pamphlet entitled "Oil Flow in Pipe Lines," by R. S. Danforth of the Kinney Manufacturing Co., published in 1921, he made use of approximate equations which were the best available in May, 1921. These were:

100	2.386	10.86	1.090
150	3.582	10.86	1.086

$$\text{For the Furol, kinematic viscosity} = 0.0218t - \frac{1.72}{t} \quad (6)$$

For the Admiralty,

$$\text{kinematic viscosity} = 0.023t - \frac{0.36}{t} \quad (7)$$

These agree fairly well with equations 2 and 3.

Conversion Tables

According to the rule adopted by the American Society for Testing Materials, the Saybolt Universal is to be used instead of the Furol instrument for time of flow less than 25 seconds on the latter and not less than 32 seconds on the former instrument. It is therefore important to be able to make conversions between these two instruments, as well as with the Redwood Admiralty. Tables III to V have been calculated for this purpose from equations 2, 3 and

$$\text{kinematic viscosity} = 0.00220t - \frac{1.80}{t} \quad (8)$$

equation 8 being for the Saybolt Universal viscosimeter. The multiplying factors given in the last line hold good for all higher viscosities. Conversion factors for use with lower viscosities than given in the tables should not be obtained by extrapolation.

Conclusions

(1) The most probable equations for the Saybolt Furol and Redwood Admiralty viscosimeters are

$$\text{kinematic viscosity} = 0.0220t - \frac{2.03}{t} \quad \text{(Furol)}$$

$$\text{kinematic viscosity} = 0.0239t - \frac{0.403}{t} \quad \text{(Admiralty)}$$

where t is the time of flow in seconds and kinematic viscosity is expressed in c.g.s. units.

(2) These equations and the equation for the Saybolt Universal viscosimeter

$$\text{kinematic viscosity} = 0.00220t - \frac{1.80}{t}$$

have been used to calculate tables for making conversions between the three instruments.

Söderberg Self-Baking Continuous Electrodes

Outline of Process of Manufacture of Continuous Electrodes at Furnace—Installations in Various Types of Furnaces: Ferro-Alloy; Carbide; Steel; Electric Pig Iron—Advantages Over Ordinary Carbon Electrodes—Cost Comparisons—Probable Trend of Future Developments

By C. W. SÖDERBERG and M. SEM
Metallurgical Engineers, Det norske Aktieselskab for Elektrokemisk Industri, Christiania, Norway

THE Söderberg self-baking electrode is a continuous electrode, which is built, baked and renewed right in the furnace where it is being used. It is an everlasting electrode, which once installed in a furnace will continue to work without change year after year through the whole lifetime of the furnace.

Manufacture of the Electrode

The principal way of making the electrode is shown in Fig. 1. The electrode consists of a casing of small-gage sheet metal (usually iron) into which ordinary electrode mixture is tamped. The casing serves to give the electrode the right shape while tamping, to reinforce the unbaked part and to help carry the current from the electrode holder to the baked part of the electrode. It further serves to protect the electrode against air corrosion. In order to give the casing a sufficiently good mechanical and electrical contact with the electrode carbon it is given a rather peculiar shape, which is shown in Fig. 2. As will be seen, the casing is provided with ribs extending radially into the electrode. The electrode is suspended in the furnace by means of an electrode holder, which is constructed as a clasp holder that can easily be moved along the electrode. The electrode is very long, and its upper part is surrounded by a tamping platform or a closed tamping house, where the lengthening of the casing and the tamping in of new electrode mixture may be carried out as often as necessary, without the workmen being exposed to the heat from the furnace. The tamping is usually done by pneumatic rammers.

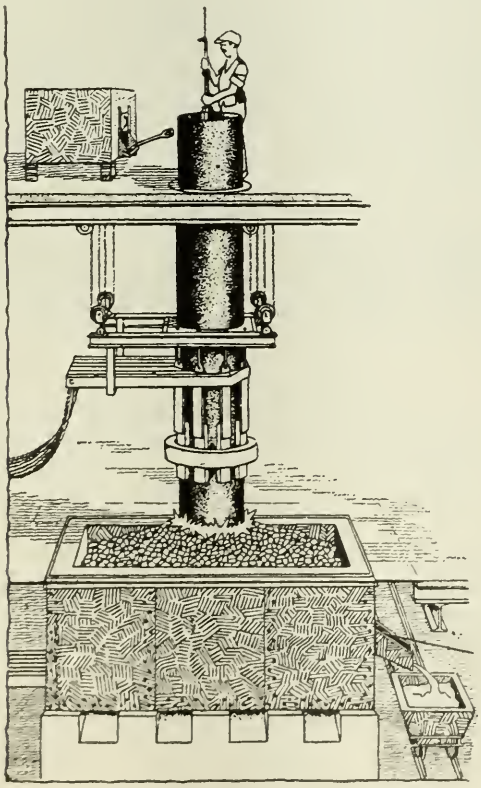

FIG. 1—METHOD OF MAKING SÖDERBERG ELECTRODES

The lower end of the electrode is placed in the smelting furnace, where it is baked by means of the heat from the furnace crater and by heat developed in the electrode itself through the electric current. The electrode will therefore consist of a lower (or internal) fully baked part, and an upper (or external) raw and unbaked part. The electrode holder is ordinarily placed on the lower baked part of the electrode, but may be placed anywhere if the cross-section of the iron casing is sufficient to conduct the current from the holder to the baked part of the electrode. When the holder is placed on the baked part of the electrode, the iron casing commonly used will average about 5 per cent of the weight of the baked carbon, the thickness of the iron in the casing being B.G. gage 22 to 16. Moving the electrode in the holder is done by simply loosening 3 or 4 screws on the holder until the electrode will gradually sink by its own weight. When the electrode has sunk sufficiently (usually 10 to 30 cm.), the screws are tightened. This operation is carried out at full current load, with no interruption in the working of the electrode, the current load being always maintained by means of the sliding contact between the electrode holder and the electrode.

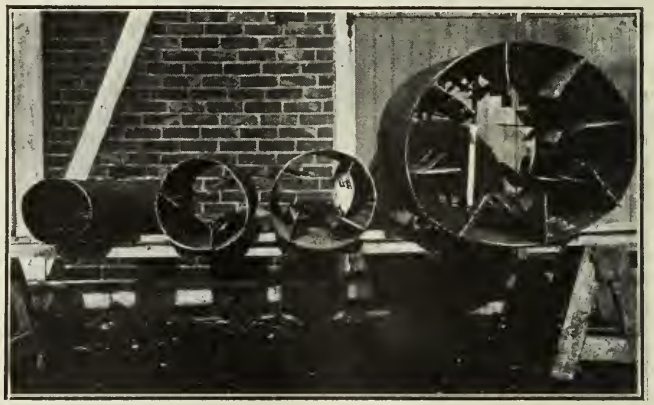

FIG. 2—CONSTRUCTION OF CASINGS

Joints Eliminated

When the electrode begins to get too short, a new section of iron casing is welded to its upper end and warm electrode mixture is tamped in. The old mixture

is still soft and will mix completely with the new mixture, making the electrode absolutely uniform and with no joints. Taking into consideration the fact that the joint is always a weak part of the ordinary threaded electrodes, it will be obvious that the Söderberg electrode has a great advantage over ordinary electrodes in this respect.

As in all open furnaces, the electrode holder is well water-cooled, and is suspended in a frame that may be moved up and down by means of a winch and regulated either automatically or by hand.

First Installation

The first furnace to use a Söderberg electrode was a ferrosilicon furnace which was put in operation by the A/S. Fiskaa Verk per Kristianssand S., Norway, in November, 1918. This first electrode was 600 mm. in diameter. In July, 1919, it was replaced by a 850-mm. electrode, and this electrode has been working continuously ever since without a single shutdown due to the electrode and without any electrode breakage—results which have hitherto been unobtainable. Electrode consumption is considerably reduced, and air corrosion is eliminated to a very great extent, due to the good protection afforded by the iron casing and the electrode holder. The baked electrode is equal in quality to the best ordinary electrodes. The cost of manufacture is relatively very low.

In May, 1921, a second electrode (rectangular, 1,150 x 500 mm.) was placed in the furnace. The furnace load was raised to about 2,000 kva. This rectangular electrode has also worked very well, with about the same efficiency and electrode consumption as the round electrode. Both electrodes are shown in Fig. 3. The furnace operates on three-phase current, Scott-connected.

Space does not permit consideration at the present

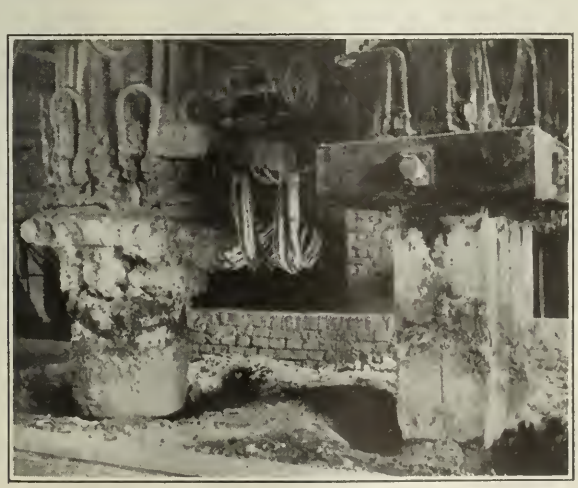

FIG. 3—FIRST INSTALLATIONS AT FISKAA VERK

time of many important and interesting details in connection with the manufacture and operation of the Söderberg electrode.[1]

Properties of the Electrodes

As mentioned above, the lower part of the electrode is perfectly baked when in use. The electrode works exactly as an ordinary carbon electrode, and needs no special attention of any kind. It looks like and has the properties of ordinary electrodes and differs in no way from them either with regard to specific gravity, electrical conductivity or mechanical strength. Common Söderberg electrodes show thus:

Specific gravity, about	1.5
Electric resistance, ohms per cu.cm.	0.007
Crushing strength:	
Kg. per sq.cm.	150
Lb. per sq.in.	2,200

The electric resistance given above is that of the cooled, baked electrode carbon. Due to the good conductivity of the iron casing, the total conductivity of the bake part of the electrode is still better than

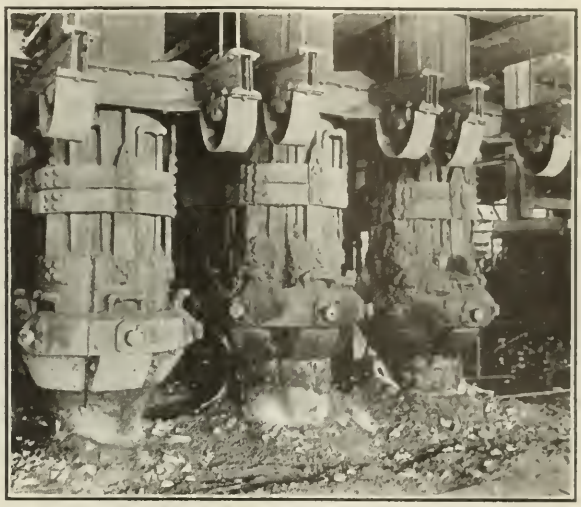

FIG. 4—ELECTRODES AT SOUTHERN MANGANESE CORP. PLANT

this figure indicates. The electric resistance of the hot electrodes (1,000 to 2,000 deg. C.) is about 0.003 ohm per cu.cm. It is therefore possible to operate the self-baking electrodes at a higher current density than ordinary electrodes, and it is further possible to regulate the electrical conductivity to a great extent by the weight of the iron casing in relation to the weight of the baked electrode carbon. In November, 1920, a 400-mm. rectangular electrode was operated continuously at a current density of 10 amp. per sq.cm. At intervals the current load was increased for a short period up to 18 amp. per sq.cm.

Due to the good electrical conductivity of the electrode and the short distance from the holder to the lower end of same, the voltage drop in the electrode is relatively low. At Fiskaa it is ordinarily between 1.3 and 1.9 volts. The heat loss in the cooling water is between 5 and 7 per cent of energy consumed in the furnace.

Other Installations

Söderberg electrodes have since been installed in furnaces all over the world. The first installation outside of Fiskaa was in a 300-kw. furnace for smelting nickel matte at Kristianssands Nikkelraffineringsverk, Kristianssand S., Norway.

Then followed an installation in a 1,800-kw. three-phase ferromanganese furnace at the Southern Manganese Corporation, Anniston, Ala. This furnace (Fig. 4), which was put in operation in July, 1920, for the manufacture of ferromanganese from Caucasian ore, was described by Prof. J. W. Richards in *Trans.*, Am. Electrochem. Soc., 1920, p. 351.[2]

[1] A detailed description may be found in *Teknisk Ukeblad*, Christiania, 1920, No. 25. See further J. W. Richards, *Trans.*, Am. Electrochem. Soc., 1920, p. 169.

[2] See also F. W. Andreae, *Schweizerische Bauzeitung*, 1921, p. 120.

About Sept. 6, 1920, an installation at A/S. Arendal Smelteverk, Eydehavn, Norway, was put in operation. The installation consists of two electrodes each 950 mm. in diameter in a two-phase 4,000-kw. furnace with two furnace craters. The furnace is running on ferrosilicon (50 and 75 per cent Si). In this furnace also the electrodes proved to be very much superior to ordinary electrodes in regard to both electrode consumption and furnace output. The consumption of Söderberg electrodes is about one-half that of ordinary electrodes, working on the same alloy in the same furnace. The direct savings obtained are so important that the total cost of the installation will be saved by less than one year's continuous running.

While the electrodes in the Arendal plant are 40 per

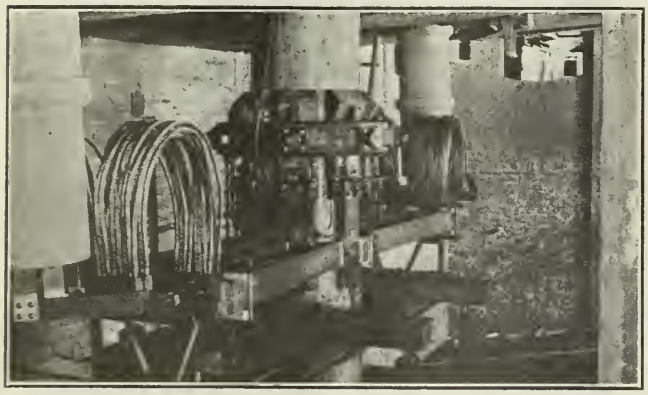

FIG. 5—GULLSPANG CARBIDE FURNACE

cent greater in cross-section than the largest ordinary single electrodes, there is no doubt that electrodes of still larger size can be made.

Application to Calcium Carbide Furnaces

Calcium carbide furnaces are also using Söderberg electrodes with excellent results. Fig. 5 shows the installation of a 850-mm. (34-in.) electrode in a 1,400-kw. carbide furnace at Gullspang, Sweden. The latest installation is in a 6,000-kw., three-phase carbide furnace in the Knapsack plant of the A/G. für Stickstoffdünger at Cologne, Germany. This furnace (Fig. 6) is provided with three 950-mm. (39-in.) electrodes, and was put in operation in August, 1921.

The electrodes are about 7 meters long, and the upper ends are surrounded by a tamping house with its floor 4.5 meters above the platform of the furnace. The house is built of reinforced concrete, and is completely closed except for a long passage leading to the outer air. Fresh air is provided through a ventilator. In order to be able to regulate the temperature in the tamping house, the concrete floor is reinforced by iron tubes for water-cooling. The temperature in the tamping house is always lower than in the smelting house.

The average results of three months' running show a reduction in the electrode consumption of about one-third. At the same time the output of the furnace per kilowatt-hour was raised considerably. At present the whole plant, consisting of nine furnaces each, rated at about 6,000 kw., is to be provided with Söderberg electrodes, and some of the furnaces are already being rebuilt.

It may be of interest to note that some carbide producers have referred to the fact that part of the iron from the iron casing of the electrode will pass into the carbide and reduce the quality of the product. This may at first glance seem to be a strong objection. However, a calculation shows that only 0.1 to 0.2 per cent of iron can be transferred to the carbide from this source, while ordinary carbide always contains about ten times as much iron. The amount in question is thus of no importance whatever.

Besides the installations described, Söderberg electrodes are at present installed or in course of installation in ferro-alloy and carbide furnaces in Sweden, Italy, France, Germany and South Africa.

Use in Electric Steel Furnaces

Also in closed furnaces the new electrodes have been tested and brought in permanent industrial use. In September, 1920, a 500-mm. (20-in.) Söderberg electrode was installed in a 7-ton Heroult steel furnace of the Stavanger Electro-Staalverk A-S., Jörpeland per Stavanger, Norway (Fig. 7). The electrode was first installed provisionally (the ordinary electrode holder of the furnace being used) and run together with ordinary electrodes. From the very beginning the results were so good that a permanent installation was made. In order to get comparative results the electrode was then run together with German electrodes of best steel furnace quality and other ordinary electrodes. The year

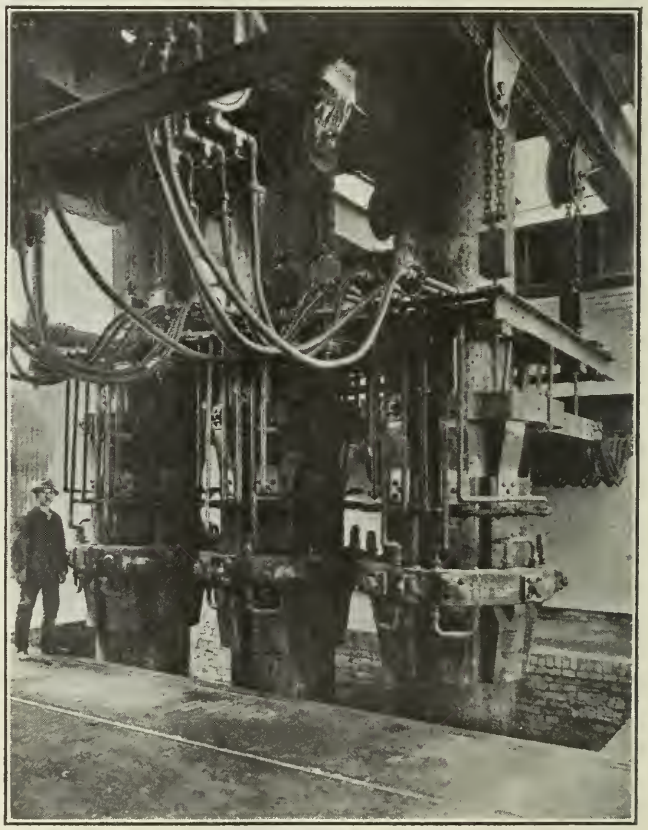

FIG. 6—6,000-KW. CARBIDE FURNACE AT KNAPSACK

1921 shows an electrode consumption for the Söderberg electrodes which is only 58 per cent of that for the German electrodes used in the same furnace, although the Söderberg electrodes were made of very poor raw materials, so that the ash content was about 15 per cent. As will be seen from Fig. 7, lengthening of the electrodes on the top of the furnace has not been provided for. The electrodes are lengthened outside the furnace, which may easily be done when using small Söderberg electrodes. When using big electrodes the changing will, however, be rather difficult, and it may

be more practical to provide a tamping platform which will tilt with the furnace and which may be removed from the furnace by means of a crane when the roof of the furnace has to be renewed. It may also be possible to arrange the platform fixed to the wall in the furnace house, in which case the platform will have to be constructed in such a way as to permit the electrodes to be tilted with the furnace. It will depend upon local conditions which arrangement will be most satisfactory from the standpoints of electrode renewal and furnace operation.

Further installations in steel furnaces are at present being made in Germany, and others are under consideration in England, France and Italy.

Another step to utilize the Söderberg electrodes in closed furnaces is the installation of 2,700-mm. (29-in.)

FIG. 7—APPLICATION TO TILTING STEEL FURNACE

electrodes in an electric pig-iron furnace of the Elektrometall type in Domnarfvet, Sweden. These electrodes were run from September to November, 1921, at which time the furnace had to be shut down owing to lack of water power. During the whole time the electrodes worked without a single breakage and with an energy load about 40 per cent higher than the load used for the ordinary electrodes in the same furnace. The potential required for the proper working of the Söderberg electrodes was about 5 volts (per set of two electrodes) lower than with ordinary electrodes, evidently due to the better contact between electrode holder and carbon and to the good conductivity of the electrodes. At present six Söderberg electrodes are being installed in this furnace.

It is therefore obvious that the utilization of the Söderberg electrodes also in the existing closed furnaces shows very great advantages. It should prove of still greater importance in the future development of closed furnaces. It is now possible to increase the size of the furnaces without increasing the number of the electrodes. This fact is thought to be of special importance in developing types of closed furnaces for the manufacture of calcium carbide and ferro-alloys.

Summary of Advantages

Operating data on Söderberg electrodes indicate the following advantages:

1. The cost of the electrodes is reduced very much.
2. The cost of special mounting and protecting the electrodes against air corrosion is avoided.
3. The baking is done without cost, as it is done by waste heat from the furnace crater. (The heat loss through the electrode is in fact less than for ordinary carbon electrodes.)
4. The electrode consumption is reduced:
   (*a*) Because the Söderberg electrodes have no electrode butts.
   (*b*) Because the air corrosion is very small.
   (*c*) Because fractures do not occur.
5. The running of the furnace is more regular because there are no stops due to change of electrodes and other troubles experienced with ordinary electrodes.
6. Every individual plant will be independent of electrode factories and will be able to make its own electrodes of the quality and shape most suitable.
7. The number of laborers can generally be reduced and the working conditions are improved, as the laborers are not so much exposed to heat.
8. It is possible to make new furnace constructions, which opens up possibilities for further development of the smelting industry.

Comparative Costs

The electrodes can be installed in most electric melting and smelting furnaces and can be built in all shapes and sizes, both round and rectangular. The cost of installation is relatively low—for two electrodes in a 2,000-kw. ferrosilicon furnace it would be about $6,000 and the time required would be from 1 to 2 months.

The cost of electrodes mounted in the furnace and ready for use is estimated at about 2 to 3c. per lb., including amortization and interest. This estimate will of course depend upon the prevailing prices of anthracite, coke, tar, pitch and labor.

The price given above is calculated for electrodes of about 34-in. diameter. Smaller electrodes will be somewhat more and larger electrodes somewhat less expensive. The electrodes may be produced still more cheaply if no anthracite is used in the electrode paste, in which case the electrodes will have to be made of foundry coke together with retort carbon or similar material. Such electrodes have been used with very good results in Fiskaa Verk for several months.

It may be of interest to show by an example what savings may be expected from the use of Söderberg electrodes instead of ordinary carbon electrodes. In most open furnaces now with 25 per cent of electrode butts, the electrode consumption will be reduced at least 35 per cent, in which case 10 per cent of the reduction is due to less air corrosion of the Söderberg electrodes. If ordinary electrodes cost 4c. per lb., the savings will be as follows:

Price of ordinary electrodes per 2,000 lb.	$80.00
Cost of mounting and protection against air	10.00
	$90.00
500 lb. of electrode butts obtained worth $10 per 2,000 lb.	2.50
Cost of 1,300 lb. electrodes consumed in furnace	$87.50
Cost per 2,000 lb. consumed electrodes	$135.00
Cost of 2,000 lb. Söderberg electrodes	40.00
Direct savings	$95.00

To these direct savings should be added the indirect

savings due to elimination of electrode changing; less repair on contacts, cables, etc.; more regular running; easier operation of the furnaces; higher output, etc.

Probable Trend of Developments

It was mentioned above that the Söderberg electrode makes possible new furnace constructions which may lead to new developments for the electric melting and smelting industry. In trying to picture the possibilities of development which the new electrode embodies for the electric furnaces, it is first necessary to review the drawbacks of the ordinary electrodes. The most prominent drawback is that they are limited in regard to length and section. It is impossible to make electrodes larger than about 7 ft., in length and 32 in. in diameter. It is, of course, possible to join electrodes over the furnace by the aid of thread and nipple, and in this way certain types of furnaces have continuously working electrodes, but this method cannot be successfully applied to other than round electrodes, and consequently not to electrode packets, and secondly the electrode joints even if ever so carefully made are liable to be the cause of trouble and fractures. To join electrodes over open furnaces is a difficult job.

Larger Furnaces Possible

Söderberg electrodes are not limited in regard to length or to section. Accumulated data all seem to indicate that electrodes are more steady and satisfactory in operation the larger they are. If there are no limits to the size of the electrodes, there will be no limits to the size of the furnaces either, and this being the case the self-baking electrodes have broken down the barrier which up to this time has impeded the evolution of large sized furnaces. When alternating currents are used for smelting, there is certainly a limitation to the size of the electrodes, or rather to the number of amperes, owing to the phase-displacement and the skin-effect, which will be quite noticeable at very high current load. Thorough investigations show, however, that when using a 50-cycle current, it is possible to make round electrodes of 1.75-meter (71-in.) diameter, if the current density in the central part is permitted to become 50 per cent less than at the surface. A 39-in. electrode would show a divergence of 10 per cent. By using twenty-five or fifteen-cycle current and allowing a divergence in the current density of 50 per cent, it is possible to make electrodes of 2½ meters (100 in.), or 3.20 meters (130 in.) respectively. An electrode of 3.20-meter diameter will at a current density of 3 amp. per sq.cm. (20 amp. per sq.in.) conduct a current of 240,000 amp., which at a voltage of 60 would develop—by means of this single electrode—14,400 kva.

Special Shapes Possible

With this last figure the ultimate limit is not by any means reached. It will be possible to reduce the number of cycles still more, or even work with direct current. Besides, the electrodes may be given such shapes that the skin-effect will be less—for example, by making the electrodes rectangular with one side much longer than the other, or by giving the electrodes the shape of hollow cylinders. It is thus clear that the electrodes can be made considerably larger than they are made today. With the increase in the size of the electrodes follows the possibility of giving the electrodes special shapes to meet the requirements of each special process. This possibility can be utilized in different ways. Being shaped directly over the furnaces in which they are used, the electrodes may thus be provided with channels running throughout their whole length. For larger electrodes such a channel may be made so wide that it will fulfill the object of the furnace shaft, serving, for example, for drawing off the furnace gases or for charging the furnace, putting on either the whole charge through the channel or only a certain part of the same. At present these forms of the electrodes are only future possibilities, but it has already been experimentally proved that hollow electrodes can be run without difficulties.

To meet present requirements it is necessary to concentrate the work on the application of the electrodes to furnaces and furnace types in operation. There is, however, no doubt that what are today the more remote possibilities of the new electrode will soon be drawn into practical use. The Söderberg electrode will become of fundamental importance to the electric smelting practice and may open up a new field of modern electrothermic industry.

Synopsis of Recent Chemical & Metallurgical Literature

Machines for Men.—In the *Gas Age-Record* for May 27, 1922, Floyd W. Parsons states editorially that great economies can be made to result from the substitution of machines for men, especially in material-handling operations. Machines do not strike, and when given proper attention they seldom or never lie down on the job.

One remedy for excessive labor costs is more machines. Here in the United States we boast of our mechanical aptness, but the truth is that in many of our industries we have been backward in adopting material-handling equipment. Not more than one-half of our manufacturers are familiar with modern mechanical methods for handling materials. If mechanical means for loading and unloading railroad cars were to be provided, so that one hour might be saved each day for each car, it is a fact that the total savings would amount to something like 2,600,000 car-hours per day, which would be equivalent to adding more than 100,000 cars to our present supply of rolling stock. The annual wage cost of handling freight in this country is more than $900,000,000. We could save 40 per cent of this sum through the installation of material-handling equipment. On the antiquated piers in New York it costs more per ton to handle food and merchandise than it costs to transport it 1,000 miles by rail.

The important thing here is not the operating cost of ships, cars and other utilities, but the cost of keeping them idle. It would be a splendid thing if every manufacturer were immediately to start making a thorough investigation of every operation inside and outside his plant, with the idea of discovering where and how men might be dispensed with and machines substituted for the work in hand. Handling practices are crude in many plants, and large economies would result from modernizing methods and equipment.

German Experience With White Alloys. — *Engineering* reports a recent discussion of die-casting alloys, in which was voiced much complaint as to the durability of many "war substitutes" and more recently exploited compositions. Sand-cast articles of the same alloys have also given considerable trouble. The long-known castings of tin-lead alloys are not strong, have low melting points and must not be heated above 100 deg. C. subsequently, but they shrink little and keep their exact dimensions. Pure zinc is not suitable for die casting; alloyed with tin, or with copper or aluminum, it answers; but tin and aluminum do not go together in general. Tinfoil containing more than 0.2 per

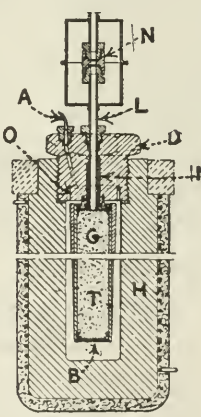
cent of aluminum may crumble in a few days. In complex alloys of zinc and aluminum the influence of tin is less clear. Zinc-tin alloys (for the mouthpieces and horns of telephone apparatus) should not be varnished at temperatures above 150 deg. C., lest a tin alloy sweat out in beads. The Siemens Co. exhibited a great many specimens of alloys, essentially of zinc-aluminum, both sand and chilled castings, which had failed, cracked, expanded or shrunk and had become distorted. The Al percentages varied between 2 and 70 in these products, which contained also copper, lead, and sometimes tin. It was mentioned that in America the use of alloys of Al-Zn, with medium Al-percentages, had been abandoned by some firms. Some new alloys are treated with acids to produce a fairly non-corrodible surface. Aging processes are advisable, and purchasers should receive full instructions as to use and be informed also as to the date when the goods were cast and after what period they might safely be mounted. That, of course, might preclude the utilization of hastily ordered parts. One zinc alloy containing 4 per cent of copper, 1 per cent of aluminum and 8 per cent of tin, and particularly the new durolith, the composition of which was not stated, were said to give full satisfaction as to strength, hardness and constancy of dimensions.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Building, Chancery Lane, London, England.

Ammonia Synthesis.—To facilitate the renewal of the catalytic material employed for the synthesis of ammonia, the inner tube containing the catalyst is rigidly secured to the removable head of the permanently fixed outer pressure tube. The inner tube *T* containing the catalytic material *G* is mounted on the exit tube *L*, which passes centrally through the screwed head *D* of the pressure tube *H*. By unscrewing the head *D*, the inner tube *T* is withdrawn and can be refilled, after removal of the gage plug; or else the whole combination *T D* may be immediately replaced by another in which the catalytic material has already been "formed," preferably by means of the pressure hydrogen issuing from the last catalyzing tube of the plant. To insure a firm screw connection between the head *D* and the pressure tube *H*, the head *D* is kept cool by passing the cold entering gases directly through it by orifice *A* and annular conduit *O*, at the same time keeping the hot exit gases out of contact therewith by employing an asbestos lining *M* for the exit tube. The screw-thread on the head *D* may be continuous but is preferably interrupted. The connection *N* between the catalyzing tube and the ammonia liquefier is immersed in cold water. Specification 171,970 and 171,972 are referred to. (Br. Pat. 174,041. Not yet accepted. Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude, Paris. March 8, 1922.)



Artificial Silk, Fire and Water Proofing.—So-called "staple fiber" which is obtained by cutting up filaments prepared from cellulose solution, etc., is rendered non-flammable by treating the formed filaments at a stage prior to the cutting up with fireproofing solutions such as are ordinarily employed in fireproofing textile materials. The treatment may be carried out after the usual drying process, or in the case of viscose filaments optionally while the filaments are in the gel condition, or in the case of nitrocellulose filaments immediately after the denitration. According to examples, sodium tungstate is deposited on the filaments by treatment with a solution of this salt in acetic acid, and aluminum tungstate by treatment with a solution of aluminum acetate and sodium tungstate in acetic acid. To waterproof the threads, an excess of aluminum acetate may be employed in the second case, or formaldehyde may be added to the bath; or the threads may be treated subsequently with formaldehyde. (Br. Pat. 175,746. W. P. Dreaper, London. April 20, 1922.)

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Process for Producing Alumina and Potash.—Harry P. Bossett uses the following illustration of his patented process: Feldspar, or any other silicate of alum and potash compound, is ground to 100 mesh and heated with excess sodium carbonate and enough sodium sulphate to take care of the potassium. Soluble potassium sulphate and sodium silicate are leached from the insoluble sodium aluminum silicate. Sodium silicate is removed from solution with lime and the potassium salt separated by evaporation. The insoluble silicate is treated with caustic soda, together with lime, to replace sodium and iron oxide to replace aluminum in the silicate. Solution of sodium aluminate is boiled, agitated, filtered and the precipitate of $Al(OH)_3$ is dried. This gives very pure products, according to the claims. (1,410,642; March 28,. 1922.)

Crude Petroleum Distillation.—In order to obtain from crude petroleum oil a maximum yield of valuable products, it is generally required that the oil be distilled to the point of dryness—that is, until the residue of distillation is petroleum coke. Offsetting the higher yield of valuable products obtained in this fashion, however, there are attendant disadvantages, which become more and more serious as the specific gravity of the crude oil increases. Thus, in a case of the ordinary quality of Mexican crude petroleum now produced and having a Baumé gravity of from 21 to 23 deg., there is obtained a coke residue very high in sulphur and amounting to as much as 14 to 18 per cent of the weight of the crude distilled with an accompanying gas loss of 2 to 5 per cent. Under many conditions this coke residue may be worth less than the cost of removing it from the stills.

Many of the large refiners, therefore, prefer merely to "skim" the ordinary grade of Mexican crude petroleum—that is, distill off only about 15 per cent—which is less than the total content of naphtha and refined oil, marketing the whole of the 85 per cent residue as a low-grade fuel oil. Aside from the waste of the valuable lubricant fractions and wax of the crude oil inherent in the use of this skimming process, there is a further disadvantageous result of considerable economic importance. This is the failure to produce a supply of a heavy petroleum oil satisfactory for use in the more highly developed cracking processes for the production of gasoline or naphtha. One reason this reduced Mexican crude is unsatisfactory in most cracking processes is that the accumulation of carbon in the cracking stills is so rapid that the amount of gasoline which can be produced before cleaning is required is cut to a very small figure. The present invention, however, provides a method of obtaining from crude oil, and particularly from heavy asphaltic-base crudes, such as Mexican, a maximum yield of valuable hydrocarbons, including heavy hydrocarbons suitable for use as a charging stock in cracking stills, without encountering any of the difficulties met with in the usual process of running such crude down to coke. In brief, the present process contemplates arresting the distillation at the point where the crude oil is reduced to a high-melting-point pitch, and then fluxing this pitch with a quantity of fuel oil sufficient to produce a product which is fluid at ordinary temperatures and capable of being marketed as a liquid fuel product. (1,413,260; Edgar M. Clark, assignor to the Standard Oil Co. of New York; April 18, 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Bakelite, Redmanol and Condensite Companies Merge to Form Bakelite Corporation

The Bakelite Corporation has taken over the General Bakelite Co., the Condensite Co. of America and the Redmanol Chemical Products Co.

The merger is the result of a suit for infringement of the Bakelite patents brought against one of the customers of the Redmanol company, the General Insulate Co. of Brooklyn. This suit resulted in an unqualified victory for the Bakelite company and the entry of a decree in the United States District Court for the Eastern District of New York on May 11.

The Bakelite patents which are thus broadly sustained cover the molding in general of phenolic condensation products by heat and pressure and the use in such products of fibrous bodies such as wood flour, asbestos, etc. In a previous suit against George J. Nicholas & Co. the Bakelite patents covering the manufacture of varnishes and solutions had been broadly sustained.

The decision against the General Insulate Co. and the bringing of other suits against Redmanol customers made it impracticable for the Redmanol company to continue its business and in order that the value of the good will, plant and organization might not be lost, it was decided to consolidate its business, including the personnel, with that of the General Bakelite Co. The Redmanol company owns a controlling interest in the Condensite company, so the inclusion of that company in the merger was possible. The Condensite company had been operating under the Bakelite patents for several years, paying royalties as the result of suit against it in 1913.

In many respects the products of the three companies are not identical; each supplements the others in important particulars. Thus formaldehyde and "hexa" are made only by Redmanol; galalith is made only by Redmanol; chlorine substitution products are made only by Condensite and transparent material is made by Bakelite and Redmanol but not by Condensite. Their phenolic condensation products also differ somewhat in their method of manufacture.

The three companies entering the merger will continue separately to manufacture and market their products, which are well known under the names of Bakelite, Condensite and Redmanol; these have found wide applications in the radio field, the automotive and electrical industries and for a large number of mechanical uses. As a result of the merger much new development and research work is already under way, from which in due course the industries using these products will greatly benefit.

L. H. Baekeland is the president of the new Bakelite Corporation, with Philip Schleussner, A. Karpen and Kirk Brown vice-presidents, the latter being also general manager. Dr. Baekeland remains also president of the General Bakelite Co., Kirk Brown president of the Condensite Co. of America and Dr. L. V. Redman president of the Redmanol Chemical Products Co.

Federal Specifications Board Forms Metals Committee

The Federal Specifications Board has organized a metals committee. G. K. Burgess, head of the Metallurgical Division of the Bureau of Standards, has been elected as chairman. The committee is to take up the following subjects in the order named: Ingots, castings, wrought metal and chains. The committee recommends that the methods of chemical analysis adopted by the American Society of Testing Materials be used for government check analyses.

Passage of Bill Providing for Helium Conservation and Development Urged by Secretary Fall

The Secretary of the Interior has given his unqualified indorsement to the bill recently introduced by Representative Kahn, chairman of the Military Affairs Committee, providing for the conservation of helium gas. Not only does he approve the bill but he urges "as a matter vital to the best interests of the country" that the bill be passed.

In his letter to Representative Sinnott, chairman of the Public Lands Committee, which has jurisdiction, Secretary Fall points out that we are in the fortunate position of having practically a natural monopoly of helium—an exceedingly valuable asset which should not under any circumstances be dissipated. He also points out that he has submitted the bill to the President and that the Chief Executive also strongly indorses the measure.

Secretary Fall points out that no commercial companies have attempted to separate helium from natural gas. For that reason the needs of the army and navy must be supplied by the government. He calls attention to the fact that of the $5,000,000 asked, $4,000,000 is needed for conservation and $1,000,000 for drilling wells, the necessary pipe lines and the construction of the plant on or adjacent to the gas field, which it is proposed to purchase, for the purpose of processing such amounts as may be necessary to supply the helium requirements of the army and navy. He mentions that the $4,000,000 for conservation is but a temporary outlay, as it is contemplated that the entire amount will be returned to the government through the ultimate sale of natural gas from the lands the purchase of which is under consideration.

The investigations of the Bureau of Mines have shown conclusively, Secretary Fall states, that helium can be conserved most effectively by holding the helium-bearing gas under ground.

With reference to the construction of a new extraction plant, Secretary Fall refers to the progress which has been made possible by the cryogenic research laboratory and the extensive development work which has led to great efficiencies resulting in decreased costs. There is every reasonable assurance, he says, that a plant for the extraction of helium now can be constructed in which both the initial cost and the cost of operation will be much reduced. Another economy would be effected by the bill, since it places all of the work under one department. Heretofore the work has been divided among the War, Navy and Interior departments.

Ominous Calm in Coal Strike Situation as Government Watches for Settlement

All directly interested in the coal strike seem to have paused, seeming to sense that something is about to happen. The quarter from which the break is likely to come does not seem to be indicated. The production of coal is climbing slowly. The country is coasting on its stocks to the extent of two or three million tons a week. The larger consumers are still very well supplied with coal, but some distress is being reported from smaller plants in the regions distant from the non-union fields. The Administration does not believe that the time has been reached when it should force a settlement. Every opportunity should be given, it is stated in Administration circles, for the parties to the strike to reach a settlement uncoerced. It is very evident, however, that there will be no hesitancy to call upon the parties to the strike to arbitrate their differences whenever the point is reached where additional coal production is essential to the public welfare.

Technical Photographic and Microscopical Society Holds Luncheon-Meeting in New York

Strikingly representative of the chemical and allied industries was the gathering of about fifty members and guests of the Technical Photographic and Microscopical Society at the luncheon-meeting of the organization at the Hotel Astor, New York, on June 14. Although the society was organized only 2 months ago, a great deal of interest in its activities and plans has been manifested by individuals and companies using photography and photomicrography in the solution of their research problems.

The incidents and events which led to the formation of the society were described by John H. Graff, its vice-president. Mr. Graff described some of the unique and valuable work that is being done today with the aid of photography. He urged that the society plan an exhibition of technical and industrial photography which will cover all the fields of its application. He remarked that great credit is due to the commercial photographer in developing the technique of the art to its present place and hoped that the society would co-operate with the commercial photographer to the mutual advantage of both.

C. E. K. Mees, of the Eastman Kodak Co., pointed out that the problems of technical photography and photomicrography are distinct in the art and said he therefore welcomed the advent of the society and predicted that through its activities it would accomplish much toward the improvement and progress of photography. He described several of the unusual and interesting problems that have been presented to the Eastman company by technical and scientific workers. Among these were requests for special emulsions for astronomical observations and other highly scientific purposes. He described the research work done in the laboratories of his company to supply these special needs, and added that although the work did not always hold prospects of immediate profit, it frequently paid richly by the newly created field.

Miss Susan B. Leiter, microscopist for the General Electric Co. at its research laboratory in New York, spoke of the extremely interesting problems that fall to the lot of her laboratory. Often, she said, problems which are beyond the scope of any of the other research departments come to her for solution, and frequently the microscope proves equal to the task. Examples of unusual problems described were those of determining the reason for failure on insulation by photographing the ends of the fibers through the microscope and of photographing the inside surface of electric lamp bulbs.

Henry Green, of the New Jersey Zinc Co., Palmerton, Pa., described the photomicrographic laboratory of that company and its work on pigments. He told of the work that is being done in his laboratory in measuring the grain size of pigments. In studying the suspension of carbon in rubber, it is necessary to use a film of rubber $\frac{1}{2}$ micron thick so that it will transmit light. A remarkable degree of accuracy has been attained in this work. The so-called superfine zinc oxide is composed of grains of $\frac{1}{10}$ micron diameter, finer than the particles composing tobacco smoke, which are being measured and studied by photomicrography.

A business session followed, during which the constitution and bylaws were adopted and steps taken to arrange for the exhibit which is to be given at the National Exposition of Chemical Industries in September. The next meeting of the society will be held in conjunction with the exposition. The following committee was appointed to arrange for the exhibit: General chairmen; J. McDowell, New England Section; A. E. Buchanan, New York Section; Textiles, New York Section—W. O. Jelleme, K. B. Cook, B. H. Foster; textiles, New England Section—R. T. Fisher, E. D. Walen, F. L. Babcock, Grimshaw; paper—J. H. Graff, D. A. Smith, T. J. Keenan; photography—J. A. Lucas, C. E. K. Mees, F. F. Renwick, A. B. Hitchins; microscopy—S B. Leiter, E. J. Wall; metallurgy—H. Green, A. E. Buchanan, G. Hiers; leather—J. A. Wilson, M. W. Cohen; rubber—K. B. Cook, B. H. Foster; testing laboratories—H. B. Gordon, Wehmer; explosives—B. Grotta; apparatus—Scheik; microchemistry—E. M. Chamot, H. Green, A. Zimmerli.

Opinions in House Differ on Muscle Shoals Offers and Construction of Dam

Agreement among the conferees on the War Department appropriation bill to provide $7,500,000 for the reopening of construction work on the Wilson dam at Muscle Shoals probably will be advanced as a reason why an immediate vote should not be taken on the acceptance of Henry Ford's offer for the government's Muscle Shoals properties. Since several years will be required to complete the dam, the steering committee in the House and the majority leaders of that body are expected to take the position that there is little to gain in rushing to a vote on the McKenzie bill. On the other hand, the supporters of the McKenzie and Wright bills will argue that there are great advantages to the public in tendering the property to Henry Ford—advantages which may be lost through the withdrawal of the offer if there be extended delay.

A statement to the effect that the President is opposed to a vote on the McKenzie bill at this time, which was published widely, was denied emphatically on the floor of the House by Majority Leader Mondell. He declared that the President had expressed no opinion as to the disposition of Muscle Shoals and that the majority leaders had not reached any conclusion as to the action they might take in regard to it. Enough is known of their views, however, to make the assumption general that they will oppose a vote on the McKenzie bill. On the other hand, there are enough friends of the Ford proposition, counting those who favor the offer minus the Gorgas steam plant, to constitute a formidable force. It is entirely within the range of possibility that they may be able to force a vote on the matter.

The Wright and McKenzie Bills

The McKenzie bill would make it mandatory upon the Secretary of War to sell and lease to Henry Ford the various Muscle Shoals properties and rights of the government. It excludes from any offer the government's equity in the steam plant on the Warrior River at Gorgas. Arrangements are being made to circulate a petition among members of the House asking for the consideration of the bill. If the signature of a majority of the members of the House can be obtained, it would make it very embarrassing for the leaders to refuse to permit consideration of the bill. In view of the fact that the House now is marking time, awaiting Senate action on the tariff bill and other measures, the chances favor success in obtaining consideration of the measure.

The eight members of the Military Affairs Committee who signed the principal minority report have reserved the right to amend the McKenzie bill so that it will include the government's interest in the Gorgas steam plant. While a bill introduced by Representative Wright of Georgia embodies the exact views of the minority, the fight will be on the McKenzie bill, introduced at the instance of the majority, which can be amended, if sufficient strength can be mustered, so as to express the views of the minority of the committee.

The Majority and Minority Opinions

It is very apparent from the report made by the majority of the committee that those members believe Mr. Ford will take over the properties if they were offered to him definitely, even were the Gorgas plant eliminated. The minority contends that the elimination of the Gorgas plant is equivalent to a rejection of the Ford offer. The minority questions the sincerity of the Alabama Power Co. in offering $2,500,000 for the Gorgas plant, but even if that amount could be obtained for it, it should not be permitted, these members say, to stand between the public and the great advantages which would accrue to it through the acceptance of the Ford offer.

"The money consideration," the majority states in commenting on the offer of Mr. Ford, "is not the vital one. If that were all, the committee would not have spent 2 hours in the consideration of the matter. It is the continuing considerations to be performed by Mr. Ford and his company over a long period of 100 years which give to his proposal its merit."

Thirteenth Annual Convention of the American Oil Chemists Society

The American Oil Chemists held their annual convention this year at New Orleans, in the Grunewald Hotel, June 5 and 6. Although only fifty-two members were present, the small attendance did not interfere with the success of the meeting. Many of the activities of the society are closely related to the work of the Interstate Cottonseed Crushers Association, and much of the time of the convention was taken up with the discussion of committee reports and papers relating directly to the chemical control of the vegetable oil industry.

The reports of the various committees were distributed in printed form, and as these had nearly all been previously published in *The Cotton Oil Press*, little time was lost in acting on their recommendations.

President's Address

C. B. Cluff, chief chemist of the American Cotton Oil Co., in his presidential address spoke feelingly of the society's loss in the deaths of Dr. F. N. Smalley and Dr. Charles Baskerville. In Mr. Cluff's opinion the fact that the membership of the organization had increased in spite of hard times was an indication of its growing strength. It had not been necessary to raise the membership dues, as seemed probable a year ago, largely because of this increase in members.

The most important matter which had come before the governing committee was the question of incorporation. This was later discussed in the convention meeting, and the officers, including the editor, were authorized to sign the charter papers for incorporation under the laws of the State of Louisiana.

The activities of the society are such as bring the officers in direct business contact with members and outsiders and may at any time result in the necessity of defending a suit. Any member of a non-incorporated society, which is legally a partnership, is liable for judgments against the society, but when the organization is incorporated, individual responsibility ceases, and for this reason it was thought advisable to incorporate.

Committee Reports

Dr. David Wesson, technical director of the Southern Cotton Oil Co., as chairman of the referee board, reported on the certification of individual chemists and firms as qualified for arbitration work. He recommended that in the future no certificates be issued to analysts connected with manufacturing concerns, as they were not eligible to act in arbitrations.

The report of the editor of the Chemists' Section of *The Cotton Oil Press*, by Herbert Bailey, chief chemist of the Southern Cotton Oil Co., recommended that suitable reprints of original articles be furnished the authors, free if possible, and if not, at cost. As the Chemists' Section was becoming better known as a medium through which to reach a large number of chemists interested in fats, oils and oil products, it is now easier to secure high-grade articles with which to fill its pages.

The color of oil and meal committee's report was presented, in the form of a paper illustrated with lantern slides, by Dr. Wesson, the chairman. He exhibited the E K. colorimeter, which has been developed by the Eastman Kodak Co., and discussed its advantages and disadvantages over the present Lovibond glasses for the grading of color of oils. This instrument has three gelatine wedges—a red, a yellow and a neutral tint—which may be superimposed in one half of the optical field. The other half is colored by light passing through a standard column of the oil to be graded.

Photographs and diagrams of another color instrument now being perfected by Carl Keuffel, of the Keuffel & Esser Co., were thrown on the screen. This apparatus is not a color comparator, but rather a color analyzer or spectrophotometer. With it the color of a sample would be analyzed rather than compared with an arbitrary standard.

Dr. Wesson showed numerous color-absorption curves made by Mr. Keuffel on oils and Lovibond glasses. One especially interesting point brought out was that with this instrument it was possible to say whether or not a cottonseed oil had been treated with fullers earth and also when a given prime summer yellow oil was bleachable.

H. P. Trevithick, chief chemist of the New York Produce Exchange, reported for the bleach test and fullers earth committee that it had done a little work looking toward the standardization of the official method for making a bleach test. It was decided that next year's committee be instructed to study various mechanical agitators in connection with the test, and if possible recommend a standard type of paddle and rate of stirring.

The oil extraction committee recommended a change in the type of container for meal samples. Dr. Felix Paquin, the chairman, said he had obtained satisfactory results by using a regular paper thimble with a cone of filter paper either outside or inside of it. He also stressed the necessity of weighing the flask before and after the extraction, under identical conditions, and suggested that the time of extraction be increased to 4 hours.

Methods for Cotton Seed Analysis

D. C. Pickard, in his report on methods for cotton seed analysis, discussed the large amount of work done by his committee on three methods (the Smalley-Copes, Pickard and Malowan) for determining the percentage of oil (gasoline extract) and ammonia in seed. The first two of these use only a 5-g. sample, while in the Malowan procedure 25 g. are taken. The agreement of chemists using the first two methods is about 0.60 per cent when the average of three determinations is taken, but the difference between individual determinations made by the same chemists may be over 1 per cent. For large samples the Malowan method is to be recommended.

In the absence of H. C. Moore, chemist of Armour Fertilizer Works, who is chairman of the ammonia committee, his printed report[1] was received and the specific recommendations considered. The c.p. sodium carbonate and ammonium sulphate which the society is now selling as basic standards for ammonia work he believes should be made official standards. Discussing the ammonia results on thirty samples of meals analyzed by eighty-eight collaborators, Mr. Moore's report points out that on the first set of ten samples one chemist did not miss the accepted average more than 0.04 per cent NH_3 on any sample, a second only 0.05 per cent, the third and fourth 0.06 per cent. In the other two groups of ten samples each the maximum variation of the analyst coming closest to the accepted average was 0.03 per cent NH_3 in each group. On the third group of samples four men came within 0.03 per cent or less of the actual NH_3 content of every meal as calculated from the reports of eighty-eight chemists.

Work of Oil Constants Committee

Dr. George S. Jamieson, chemist in charge of the oil, fat and wax laboratory of the U. S. Bureau of Chemistry, reported the results of the analysis of twenty-two samples of authentic peanut oils collected during the past 3 years. This is the work of the oil constants committee, of which Dr. Jamieson is chairman.

The society's co-operative analytical program has been carried on, since the death of Dr. F. N. Smalley, by Herbert Bailey. His report[2] was not read, but the continuance of the work was fully discussed and finally referred to the governing committee. The committee has since arranged that next year only thirty meal samples be distributed and only three certificates and the loving cup be awarded. The compilation of results and all details, except the preparation and distribution of samples, will be in the hands of the ammonia committee. The samples of crude oils for refining tests, and of fats for determination of iodine number and titer, will be distributed by J. H. Morrison, chemical director of the Procter & Gamble Co. His committee will also tabulate the results as reported and handle all details of this work.

Mr. Bailey's recommendation that in the future the co-

[1] *Cotton Oil Press*, vol. 6, No. 1, p. 46.
[2] *Cotton Oil Press*, vol. 6, No. 1, p. 36.

operative analytical program be known as the Smalley Foundation, in honor of the late Dr. Smalley, who had so unselfishly given a great deal of time and energy to this work, was unanimously approved.

R. H. Fash, vice-president of the Fort Worth Laboratories, as chairman of the refining test committee, submitted brief reports by W. G. McLeod, of Morris & Co., on corn-oil refining, and on coconut oil by A. Porter Lee, New York Produce Exchange, in addition to the cottonseed oil report by J. H. Morrison, previously published.[3] The year's work on corn-oil refining covered a comparison of results obtained with straight and curved paddle agitators and uniform stirring speed versus a slowing down of the agitation after the break. So far as the few results reported go, variations in paddles and stirring procedure have no appreciable effect on refining losses.

Mr. Lee stated that in studying the effect of varying the concentration of caustic soda solution on the refining loss of coconut oils, he had observed in some oils a material which was neither meal nor hull fiber. This varied from 0.01 to 0.1 per cent in different oils and seemed to be a partly waxlike body and partly a water-soluble gum.

Co-operation With the Government and Research Institutions

During the past year a committee of the Oil Chemists Society, of which Dr. J. H. Shrader, director of the Bureau of Chemistry and Food, Baltimore City, is chairman, and a similar committee from the Interstate Cottonseed Crushers Association, Edward Barrow, of Barrow-Agee Laboratories, Memphis, chairman, have worked together in co-operation with the government on basic research problems. Dr. Shrader's report outlines four problems already accepted by the U. S. Department of Agriculture for investigation: (*a*) Breeding cotton seed to increase oil content; (*b*) crude oil investigations; (*c*) rancidity investigation, and (*d*) cottonseed meal investigations. Mr. Barrow reviewed briefly the progress already made by Dr. Jamieson on crude cottonseed oil, and offered resolutions of appreciation to the Secretary of Agriculture for his interest and valuable assistance in the solution of problems of the vegetable oil industries. Two papers, one by Dr. Wesson and one by Dr. Jamieson, were read in connection with this work. The former will be published in a subsequent issue of this magazine.

Determining Neutral Oils

Dr. Jamieson, in the course of his remarks, made the following statements:

> Every chemist who applies the official refining test to crude vegetable oils often wonders why there is not more of a proportional relation between the refining loss and the percentage of free fatty acids. The reason in most cases is not that the crude oil with the high loss and low acidity contains more impurities and less oil than the oil with low loss and higher acidity. The reason is inherent in the test.
>
> It is possible, however, to determine, among other things, the absolute amount of neutral oil in the crude. When a crude vegetable oil, dissolved in petroleum ether, is shaken with a large excess of an aqueous potassium hydroxide solution, the free fatty acids are neutralized, the coloring matter is precipitated and certain compounds of fatty acids other than glycerides are decomposed. Addition of a considerable quantity of 50 per cent alcohol causes the mixture to separate into two layers upon standing, an upper clean petroleum ether solution of refined oil and a lower alcohol alkali layer containing the saponified fatty acids, the coloring matter, more or less precipitated matter and other impurities.
>
> This treatment does not decompose fatty acid glycerides. When the method was applied to absolutely dry and neutral refined oils, 100 per cent recovery of neutral oil was obtained. When applied to commercially refined cottonseed oil, a refining loss amounting to 0.20 to 0.22 per cent resulted.

Award of Certificates and Presentation of Cup

Following his report as chairman of the co-operative analytical program, Mr. Bailey awarded in behalf of the society a number of certificates for proficiency in the analyses of oils, fats, meals and fertilizers. The winners of these certificates were chemists who had excelled all other contestants in the co-operative work. Later, at the banquet, he also presented to Dr. H. B. Battle the silver loving cup which is annually given to the chemist who had the highest standing in the check meal work. In connection with this presentation Mr. Bailey paid tribute to the late Dr. Smalley, stating that in his opinion the greatest good accomplished by the society for the chemists in the oil industry was that resulting from the check meal work. Dr. Smalley, with his wonderful far-sightedness, had seen the advantages which would be obtained if all the chemists of the society would analyze every week a portion of a uniform sample of some oil-bearing material. He had given an immense amount of time and thought to the details of this analytical contest and the increase in accuracy as indicated by the results reported each successive year was evidence of the great good which had been accomplished.

L. M. TOLMAN, CHIEF CHEMIST, WILSON & CO., CHICAGO, AND NEWLY ELECTED PRESIDENT OF AMERICAN OIL CHEMISTS SOCIETY

Election of Officers

Election of officers for the ensuing year, held during the closing day of the convention, resulted in the following new officers:

President, L. M. Tolman, chief chemist, Wilson & Co., Chicago; vice-president, Dr. H. B. Battle, the Battle Laboratories, Montgomery, Ala.; secretary-treasurer, Thomas B. Caldwell, Law & Co., Wilmington, N. C. Later, at the meeting of the governing board, Herbert S. Bailey was re-elected editor of the Chemists Section of *The Cotton Oil Press*.

The convention was concluded on Tuesday night when the members of the society, the New Orleans Section of the American Chemical Society, their wives and friends enjoyed a delightful banquet at the New Orleans Yacht Club. Following the dinner, Mr. Tolman, the newly elected president, acting as toastmaster, introduced a number of speakers, including several of the past presidents as well as the newly elected officers of the society.

Dedication of State Ceramic Building at Rutgers—Dean of Ceramic Industry Honored

Tuesday, June 13, was not only a history-making day in the ceramic industry in New Jersey, but one of memorable record for the entire field of ceramics in all parts of the country. Through a culmination of events, on this day there was dedicated the finest ceramics building, school and research station of which the industry can boast and signal honor was accorded to the dean of this profession, through the conferring of the degree of Doctor of Science by Rutgers College, New Brunswick, N. J., at its one hundred and fifty-sixth commencement year.

To Edward Orton, Jr., Columbus, Ohio, formerly of Ohio State University, fell the privilege and honor of being the first ceramic engineer ever honored with a degree in this country. It was conferred by W. H. S. Demarest, president of the institution, during the commencement exercises at the morning session, in "recognition of ability and achievements, particularly in the line of ceramic research work for the State of Ohio, and as a director of the first college of ceramics in this country."

As an associate for this honor, Dr. Orton was preceded by Thomas A. Edison, who received a similar degree.

In commenting upon the honor conferred, Dr. Orton said at the alumni luncheon following that he deemed it not as a personal gift or achievement, but rather as a mark of recognition for the ceramic industry that would go to inspire his fellow workers in the craft, as well as the young men coming along who might be considering the ceramic field as one of their choice for the future.

Dedication of Ceramics Building

Located on the Neilson Campus, on line with the chemistry building and Ballantine gymnasium at the institution, the new ceramics building, shown in the accompanying illustration, has been in course of construction for about a year past. The structure was made possible by a state appropriation of $100,000, to which has been added at least $25,000 in contributions from companies and individuals in the industry in the state, embracing both funds and materials. In all, more than eighty companies contributed to make the new building a success.

NEW CERAMICS BUILDING, RUTGERS COLLEGE

The occasion of the official dedication was fittingly arranged for 3 p.m., and faced by an assemblage of more than 150 persons, President Demarest opened the ceremony with a few appropriate remarks. He said that the dedication commemorated the twentieth anniversary of the ceramics department at Rutgers College, and that the fulfillment of the desire for a suitable structure to represent this branch of learning was not only due to the state, but to the energy and untiring efforts of prominent members of the New Jersey Clay Workers' Association and Eastern Section of the American Ceramic Society.

Principal Address by LeRoy H. Minton

The principal address was made by LeRoy H. Minton, president of the New Jersey Clay Workers' Association. He said that in outlining the work of the organization in connection with the new structure the industries of the state were divided roughly into nine groups. These included the sanitary ware manufacturers, embracing porcelain and chemical stoneware materials; electrical porcelain manufacturers; terra cotta manufacturers; brick and fireproofing manufacturers; firebrick and refractory manufacturers; floor and wall tile manufacturers; general ware manufacturers; sand and gravel producers. He commented upon the work of Prof. George H. Brown, director of the department and secretary of the association, and said that the building would stand always as a monument to his work.

Other Speakers

Former Senator Thomas A. Brown, who was instrumental in having the appropriation bill for the ceramic building pass the state legislature and receive the Governor's approval, spoke about the value of the institution to the state and its significance to the younger generation coming forward in the ceramic industry.

He was followed by Frank H. Riddle, president of the American Ceramic Society, who made a brief address of congratulation to men in the clay-working industry in the state in achieving their aims in the completion of the new building, and its immediate utility for research and students.

Dr. Orton Pays Tribute to Pioneers

Edward Orton, Jr., the last speaker on the program, traced the growth of the ceramic industry in this country from 1883 when, as a college student, he was given the task of preparing a chapter upon the clays and clay-working industries of Ohio for a volume on economic geology that was to be issued by the state. He paid high tribute to the small group of men who in 1894 approved his plan for the establishment of the first technical school for the clay workers in America. Among these he mentioned Ernest Mayer and F. W. Walker, Beaver Falls, Pa.; Homer Laughlin, East Liverpool, Ohio; Stanley G. Burt, Cincinnati, Ohio; Charles A. Bloomfield, Metuchen, N. J.; A. O. Jones and R. C. Burton, Zanesville, Ohio.

In conclusion he said: "Has ceramic engineering made a permanent place for itself in the field of permanent education? That question may be answered by another, What is permanent? Nothing is permanent in nature—all is in a state of flux. But, with the constantly increasing substitution of the products of the forests by the great group of silicate products, ministering increasingly to the needs of man and requiring with the passing of the decades and centuries always a more critical conservation of thermal energy and greater economy of human labor, we can be sure that they will require trained direction in increasing proportion. Courses of study and names of subjects will change, but that technical schools will cease to produce that kind of educated leadership which we now know as the ceramic engineer is not thinkable."

The Ceramics Building

The new ceramics building is 45x102 ft., of fireproof construction throughout, two-story and basement. The exterior is of red brick, with buff terra cotta trimming, including a base course at the first floor, a stringer course around the second floor, and terra cotta cornice. Terra cotta medallions, depicting certain branches of the clay-working industry, later will be inserted between the windows at the tops and there will be a terra cotta doorway at each entrance. The interior walls of the structure are of common brick, with hollow tile ceilings and floors throughout.

The basement comprises physical testing room, brick machinery room, sagger and plaster shops and miscellaneous operating departments.

The first floor contains a pottery laboratory, pottery storeroom and ceramic materials laboratory. A stairway leads from the pottery laboratory to the kiln room. At one end of the first floor there is a class room and four research laboratories.

The second floor is arranged with offices, library, drafting room, chemical laboratory and at one end, a museum or assembly room extending across the entire end. This

room, 25x42 ft., is finished throughout with tile, including a red tile floor, tile paneling and inserts around the ceiling, with tile fireplace and mantel.

Summer Meeting of New Jersey Clayworkers' Association

To permit visiting ceramists from different parts of the country to be present at the regular summer meeting of the New Jersey Clay Workers' Association and Eastern Section of the American Ceramic Society, this gathering was arranged on the day following, Wednesday, June 14, at the Country Club, Trenton, N. J.

The opening address was a paper by LeRoy H. Minton, president of the association, on the subject of the Royal Berlin Porcelain Works, Germany, which he visited on a recent trip abroad. The paper was illustrated with a number of interesting lantern slides. In this line of hard porcelain manufacture, it was pointed out, the principal clay used is the Halle variety, originating from a decomposition of granite rock and mixed abundantly with sand and other materials. The "flow" of operation through the plant was described, including the settling tanks, preparation of body, filter presses, period of aging, drying and firing of bisque ware, glazing and color decorations. Particular reference was made to the different types of kilns installed at the plant, including three-story kilns, each chamber forming an individual operating unit. A chamber kiln of twenty-two compartments is also in service.

Past, Present and Future

Departing from the usual custom of a set program, President Minton said that the time was opportune for comments on the "Past, Present and Future" of the ceramic industry, and he allotted these subjects to Charles A. Bloomfield, A. V. Bleininger and Frank H. Riddle, respectively.

Mr. Bloomfield spoke interestingly of the days gone by, of the obtaining of an appropriation for the first ceramic department at Rutgers College 20 years ago, in which he was instrumental, and of the growth of the ceramic industry and ceramic education up to the present time.

At this point Mr. Bleininger gave a pertinent résumé as to present-day happenings. He said that the trend decidedly was toward research and investigation, of the study of clays in different forms. A more definite understanding of plasticity is being obtained, and of the absorption of gases and liquids. Firing conditions, he pointed out, are still poor, and better kilns must be secured in the days to come; better temperature control is essential and other phases of firing the ware. The investigation of the more obscure phenomena, such as now going on, cannot help but bring about immeasurable benefit and profit.

Frank H. Riddle, of the Champion Porcelain Co., Detroit, Mich., president of the American Ceramic Society, said that the future would show a development of plant control, an amalgamation of plant management and the technical end of the business. The mechanical phases of the ceramic industry also, he said, presented great possibilities, and machinery of improved type for different features of manufacture naturally would come as a result of research and practical investigations. He said that in the years soon to come what are now known as "super-refractories" will be known as normal materials, for the general trend is toward the development of refractories for higher temperatures. Other fluxes, he prophesied, will come into use—materials which are now available but little known. Magnetic separation is another matter offering great possibilities, and one that is destined to receive concerted interest and attention in the future. Tunnel kilns and kilns of other types are open to big improvement, and this will come as the industry advances. Still another subject of importance is the control of gas conditions, so necessary in high temperatures, and this will ensue as a natural order of development. He prophesied that oil-gas producers will come into far more extensive use in the future.

Dr. Edward Orton, Jr., was the next speaker, and he commented extensively upon the new ceramics building and what it meant to the state and to the industry. He pointed out the necessity for getting the right kind of students, and the advantage of actual shop work during the term of technical training. He said that the ceramic manufacturers in the state should co-operate intelligently in selecting bright men from their plants for a course of instruction at the institution.

Ross C. Purdy, secretary of the American Ceramic Society, followed Dr. Orton, and congratulated the association members on their attainments in connection with the new ceramics building. He spoke at length upon the society he represents, and features of research now going on through different committees.

Succeeding speakers were Charles Howell Cook, president of the Cook Pottery Co., Trenton, and August Staudt, head of the Perth Amboy Tile Works, Perth Amboy, N. J., both past presidents of the association.

Chemical Warfare Service Appropriation Urged on Basis of Research Need

Testifying before the Senate Appropriations Committee in support of appropriations for the Chemical Warfare Service, Brigadier-General A. A. Fries, chief of that branch, stressed the importance of continued research on chemical warfare. Whether or not the army uses this weapon, it is important that all information possible be available for defensive measures. He referred to mistakes made in the war by both sides in the use of poison gas, all of which were due to lack of research. He also emphasized the importance of fundamental research in other fields in which the government is directly concerned.

The War Department's estimate as presented to the committee provides 272 combat troops for the Chemical Warfare Service. Senator Hitchcock of Nebraska was moved to ask why there should be combat troops in that branch of the service. General Lassiter, replying for the department, explained that the chemical warfare troops are authorized by law. The department is considering the question of reducing the number to a point necessary to comply with the terms of the treaty. The law calls for 100 officers and 1,200 enlisted men in the Chemical Warfare Service for an army of 280,000 men. The Service now has 87 officers and 550 men.

General Lassiter agreed with the comment of Senator Sutherland that the treaty does not involve the abandonment of all research along chemical warfare lines, interpreting it as providing only against the use of gases in warfare. He stated that the War Department would present a project on the Chemical Warfare Service personnel to Congress later.

Associations to Meet at Chemical Exposition

Several leading associations of the chemical industry have definitely arranged to meet at the Eighth National Exposition of Chemical Industries, which will be held during the week of Sept. 11 to 16 at the Grand Central Palace, New York. The special meetings which have already been scheduled to be held at the Grand Central Palace during the week of the exposition include a meeting of the American Ceramic Society, the Technical Association of the Pulp and Paper Industry and the Salesmen's Association of the American Chemical Industry. Other technical and commercial groups connected with the chemical and allied industries are also expected to meet at the time of the exposition, but definite arrangements for the latter have not as yet been made.

The exposition was purposely scheduled to come between the meeting of the American Chemical Society in Pittsburgh, Sept. 6 to 9, and that of the American Electrochemical Society in Montreal, Sept. 21 to 23, so that September will as usual be a busy month in chemical circles.

Helium Manufacture Described by Moore in England

The English press gave prominent notice to the public lecture delivered at the University College of London on May 24 by R. B. Moore, chief chemist of the U. S. Bureau of Mines. Dr. Moore's topic was "Commercial Manufacture of Helium by the Government of the United States."

Consideration of Dye Embargo in Senate Tariff Discussion Again Delayed

While some delay in taking up the dye embargo feature of the tariff bill has been occasioned by a variety of causes, it can be stated definitely that the effort of its opponents to have it go over until the administrative provisions of the bill are reached has been unsuccessful.

It has been stated that the proponents of the embargo, secure in their position by reason of the indefinite extension of the existing embargo, are unconcerned as to the delays and really are hopeful that the bill itself might be recommitted so that the dye industry could be assured for a considerable time at least of that restriction on imports. Anyone who has had contact with the dye manufacturers who have come to Washington in connection with this legislation is in a position to refute such a charge, as their entire effort has been to obtain the speedy adoption of the bill and the termination of the uncertainty. Senator Frelinghuysen, who is leading the fight to make possible the maintenance and encouragement of the domestic chemical industry, has been almost abrupt on several occasions in demanding that further delay in taking up the question be prevented.

When Senator King was in the midst of a denunciation of what he terms the lobby in the interest of the embargo, Senator Frelinghuysen asked why he did not give some attention to the agents of the German dye interests who seem to have been extended office facilities in the Senate Office Building.

Revise Potash Schedule

Further revision of the potash schedule in the tariff bill has been decided on by the Finance Committee. In place of the proposed duties for 5 years as previously agreed on, the committee has decided to place potash on the free list and substitute for a tariff a bounty to American producers to aid them in producing potash. The change was explained to the Senate by Chairman McCumber of the Finance Committee. He said that Senator Hale of Maine had asked that potash be placed on the free list. The committee tentatively proposes, in lieu of the tariff, to encourage the American industry by granting a bounty equivalent to the tariff rate originally proposed. He stated that if the annual production of potash were 50,000 tons a year, the bounty would amount to not more than $2,500,000 for the first and second years, $2,000,000 for the third year, $1,500,000 for the fourth and $1,000,000 for the fifth year.

Tungsten and Chromium Rates

The Senate adopted a duty of 60c. a pound on the tungsten content and 25 per cent ad valorem on ferrotungsten, metallic tungsten, tungsten powder, tungstic acid and other compounds of tungsten.

During the tariff debate Senator Walsh of Montana inquired why a duty had not been placed on chrome ore. Senator Smoot of Utah explained that it is due to the fact that chrome ore production is scattered and the American product is inferior to the imported. Senator Walsh did not agree, saying there is no limit to the amount of the ore that could be produced and that it is equal in quality to that produced elsewhere.

Shortridge Resolution Would Give President Power to Act on Reparation Dyes

A resolution has been introduced by Senator Shortridge granting broad powers to the President to be used in meeting the reparations dyes situation. Senator Shortridge is chairman of the sub-committee which has just completed its investigation of the dye situation.

The resolution provides that the President be authorized and requested to take such measures as may be required to obtain for the United States the dyestuffs and drugs to which it is entitled under Sec. 1, Art. XI of the treaty of peace between the United States and Germany.

The need for immediate and decisive action in arranging for a satisfactory receiving system for the reparations dyes before June 30, when the present arrangement terminates, was brought out during the investigation.

Summary of Chemical and Oil Companies Organized

During the month of May twenty new companies were organized, with individual capitalization of $50,000 or more, to manufacture chemicals, chemical byproducts, drugs and affiliated products. The aggregate indicated investment was $3,671,000, as compared with $20,055,000 in the preceding month, when exactly the same number of such concerns were formed. During the same month of a year ago the total capitalization of such new companies was $12,400,000.

Seventy-three companies were organized in May with capitalization of $50,000 or more, to engage in different branches of the oil industry, with total indicated investment of $105,595,000.

Personal

Dr. Robert Calvert is now in charge of the Celite Products Co.'s laboratory at Lompoc, Cal.

F. E. Coombs, consulting chemical engineer of San Francisco, Calif., has accepted a position with the Department of Commerce. After some months in Washington he will be stationed in Havana, Cuba.

E. P. Gillan has resigned his position as chief chemist with the American Cereal Syrup Co. to accept one with the Chicago Starch Co.

James B. McNair, chemist with the Bureau of Internal Revenue, has been transferred from Washington, D. C., to Chicago, Ill.

George N. Moore, president of the Shaffer Oil & Refining Co., Chicago, Ill., has resigned. He will become head of a new oil-refining company now being organized.

J. C. Pearson, chief of the cement investigations of the Bureau of Standards, has just returned from a long Western trip. While in California he arranged for the investigation of cement sewer pipe which the bureau is to make during the coming year.

Prof. Charles Hyde Warren has been elected by the Yale Corporation as director of the Sheffield Scientific School to succeed Russell H. Chittenton. Prof. Warren is an alumnus of Yale, class of 1896, and since 1900 has been on the faculty of the Massachusetts Institute of Technology. Since 1915 he has been professor of mineralogy. Dr. Chittenton's retirement follows a determination made when he offered his resignation a year ago. He has been a member of the Yale faculty since his graduation from Sheffield Scientific School 47 years ago has been head of Sheff. since 1898.

Obituary

S. C. Ellis of Dallas, Tex., chemist and bacteriologist, formerly in charge of the municipal laboratory at the City Hall, died on May 31, at San Angelo, Tex., where he had gone on account of poor health. He was 30 years of age, and served 18 months overseas in the World War. Mr. Ellis is survived by his wife and young daughter.

A. H. Kersting, president of the Clinton Sugar Refining Co., Clinton, Iowa, died suddenly at his home on June 1, as a result of a stroke of apoplexy.

Alexander H. Smalley, chief chemist of the Nucoa Butter Co., Bayonne, N. J., died on June 8, as a result of injuries received in an explosion, followed by fire, in the chemical laboratory at the plant on the date noted. He was 25 years of age and a graduate of Cornell University.

E. R. Kemp, chairman of the board of directors, Sinclair Oil & Gas Co., Tulsa, Okla., died on June 9 at Roosevelt Hospital, New York, following an operation for appendicitis. He was 50 years of age, and widely known in the Middle Western oil-refinery industry. Mr. Kemp is survived by his wife and three children.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Studies of Depreciation and Obsolescence Offer a Promising Field for Chemical Trade Associations

Depreciation and obsolescence are stumbling blocks in almost every cost-finding system, but particularly in the chemical industries are their difficulties most evident. The cost accountant in these industries is often confronted with other very serious problems, such as those arising from joint products and byproducts, inter-departmental transfer of materials, off-standard products, etc., and in the maze of these difficulties he is likely to accept without question some very arbitrary method of handling depreciation and obsolescence charges. Or, as is the case with some chemical firms, these items are not regarded as proper elements of current costs and are taken into consideration only at the end of the year or some other fiscal period, when a definite sum is written off against profits to cover depreciation and obsolescence. And very often this amount is influenced by the amount of profits shown on the credit side of the ledger.

A Plan for Group Studies

For tax purposes, however, there is a very definite need for accurate methods of determining these charges and particularly in such a manner as will receive the indorsement of the Treasury Department. In the hope of assisting manufacturers in this connection, the Fabricated Production Department of the Chamber of Commerce of the United States has worked out a plan for handling these problems through the agency of the trade associations within the different industries. The plan provides for the appointment of a committee on depreciation, which should preferably consist of from five to seven engineers, cost accountants and plant superintendents selected from the industry. This committee would prepare a questionnaire providing for the listing of equipment and other units of utility[1], their cost, estimated scrap value and years of useful life.

Before sending this questionnaire to the manufacturers, the department recommends that certain preliminary points, such as the following, should be cleared up:

(*A*) *Method of Charging Maintenance, Renewals and Depreciation.* It will not do merely to average the various estimates of useful life provided by the manufacturers of a given line, because the methods of charging maintenance, renewals and depreciation may not be the same. Thus one manufacturer may charge as maintenance all repairs and partial renewals. By this method the laying of a new roof on a building would be charged as maintenance. Another manufacturer may charge to maintenance only such items as tend to keep the property in the same general condition. The laying of a new roof adds to the life of the asset and accordingly would be charged to the depreciation reserve. The first method gives a high maintenance rate and a low depreciation rate. The second method gives a low maintenance rate and a high depreciation rate. Suppose the first manufacturer charges 2 per cent for depreciation and the second 8 per cent. It will not do to average these rates and set 5 per cent as the guide for the industry. That would not give a true picture of actual conditions.

The Elements of Depreciation

(*B*) *A Statement of the Elements of Depreciation.* Accompanying the questionnaire should be a statement of the elements entering into depreciation, wear and tear, and obsolescence.

Wear and tear is defined as "that uniform wear-out and decay which repairing is unable to check" and it is dependent upon the amount of use, the amount of care, the quality of the installation and the natural hardships to be overcome.

Obsolescence arises from "an inability to compete in kind, in quality or in cost of desired results with later forms of the same utility." Allied there is that change in demand which displaces the whole life of the equipment.

The department points out that it is important for the depreciation committee to obtain sufficient facts for it to come to a conclusion as to which is the factor, obsolescence or wear and tear, determining the useful life of a given unit of utility. Certain chemical equipment is often not given the opportunity to wear out, it is replaced so rapidly because of improvements in the art. Clearly obsolescence is here the determining factor.

(*C*) *Determining Stated Conditions of Use.* Guide rates of depreciation for an industry presuppose stated conditions of use—the number of days of operation in a year, the number of hours of operation per day, a standard of maintenance, external conditions such as climate and road, etc.

With the normal conditions of use stated, it will be possible to provide for variances thereof upon a scale of percentages. Thus during the war additional rates of depreciation were allowed for overtime operation, and when depreciation can be based on an incident of production, capacity or performance, it may be feasible to scale the rate of depreciation for subnormal production.

After these questionnaires have been returned by the manufacturers, the committee is expected to prepare a digest of them, which is submitted to the industry for criticism and comment. Upon revision a conference can be arranged with experts of the Treasury Department in order that the depreciation data may be checked by them. When so checked the rates of depreciation should be promulgated as guide rates for the industry. It should be thoroughly understood, of course, that these depreciation rates would be merely suggestive and not mandatory and that in the last analysis the manufacturer must determine depreciation allowances from his own individual experiences.

Chemical manufacturers wishing to perfect this phase of their cost systems will do well to consult the Fabrication Production Department's very interesting pamphlet on "Depreciation—Its Treatment in Production." More general in character but of equal importance to the chemical industries is the report of the cost accountants' committee of the American Dyes Institute, which was published in 1920 under the title "Uniform Cost-Accounting Methods."

[1] "Unit of utility" is defined by the Treasury Department to mean a single purposed mechanism or part of a construction, subject to such like conditions of use that it would naturally be repaired or replaced as a unit.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	156.89
Last week	157.93

June, 1917	222	June, 1918	272
June, 1920	274	June, 1921	147
April, 1918 (high)	286	April, 1921 (low)	140

During the past month this index number has receded almost 4 points—from the recent high of 160.49 on May 24 to 156.89 for the current quotation. Of the 25 commodities on which this index is based, lower prices were recorded during the past week for 6—viz., formaldehyde, glycerine, potassium carbonate, soda ash, caustic soda and linseed oil.

Organization and Financing of the International Carbon Corporation

A new corporation to be known as the International Carbon Corporation has been organized to acquire control of the Darco Corporation and the patent rights for the manufacture of this decolorizing carbon. The operation of the manufacturing plants of the new corporation is under the direct supervision of the Atlas Powder Co., of Wilmington, Del., and the management of the Darco Sales Corporation is under the direction of the Columbian Carbon Co.

The authorized capitalization of the International Carbon Corporation consists of $2,500,000 of 8 per cent cumulative preferred stock, of which $863,300 is outstanding, and 300,000 shares of no par value common stock, of which 231,000 shares are outstanding.

Darco, the product to be manufactured, is produced from lignite by a patented process. It is used as a substitute for animal charcoal in the refining, decolorizing and deodorizing of a large number of staple products. Included in the list of industries in which decolorizing carbons are already finding use are sugar, glucose, maltose, lactose, sirups, glue, gelatine, vegetable oils (cottonseed oil, corn oil, peanut oil, coconut oil, olive oil, soya bean oil), fish oils, lard and butter substitutes, glycerine, alcohol, acids, wines, pharmaceutical chemicals, dye intermediates and photographic and other synthetic organic chemicals.

A unit producing a ton a day has been in operation for more than a year at Marshall, Tex. It has just been announced that a 4,000 ton per year plant has been constructed and has commenced operation. The plant is adjacent to a large deposit of lignite and it is reported that an ample supply of natural gas is available for fuel.

New Financing for Atlantic Refining

A group of New York bankers, including the Equitable Trust Co. of New York, Cassatt & Co. and Blair & Co., Inc., recently purchased $15,000,000 15-year 5 per cent noncallable gold debentures of the Atlantic Refining Co. On the first day they were offered for sale the issue was largely oversubscribed and the subscription lists have since been closed.

The Atlantic Refining Co., it will be recalled, owns and operates refineries at Philadelphia, Franklin, Pa., Pittsburgh, and Brunswick, Ga., besides owning extensive sales equipment, warehousing and storage facilities throughout Pennsylvania, Delaware and the New England states. Its total deadweight tonnage of tank steamers and various marine equipment is estimated at 75,000 tons. A subsidiary of the Atlantic is interested in the production of crude oil in Mexico.

American Metal Reports Earnings in First Four Months of 1922

Consolidated profit and loss account for the first four months of 1922, according to C. M. Loeb, president of the American Metal Co., Ltd., shows net earnings for that company of $762,708, after allowances have been made for depreciation, etc.

After completing the financing that is now under way, the American Metal Co. will have $5,000,000 preferred stock authorized and outstanding and 536,000 shares of an authorized issue of 1,000,000 shares of common stock having no par value.

The New York Market

NEW YORK, June 19, 1922.

Business during the past week in the chemical market has been generally quiet due to the influence of a number of different elements. The coal strike, the uncertainty of tariff legislation, the possibility of a railroad strike and the failure of the loan negotiations in Europe have combined in causing a general slackening in industry. With the exception of a few commodities, the entire chemical list showed no outstanding features. Flouride of soda and acetate of soda recorded net advances for the week, while prussiate of soda, nitrite of soda, formaldehyde and bleaching powder were quoted lower under keener competition and an abundance of spot stocks. The export inquiry for caustic soda showed considerable improvement and so too did the domestic inquiry.

Crude coal-tar products continue firm and in good demand. Producers of cresylic acid, benzene, solvent naphtha and toluene are experiencing a steady call from the various consuming industries. Intermediates, on the other hand, are quite irregular. Aniline oil, beta naphthol and para nitraniline are much easier under a slackening of demand and are subject to pronounced shading.

INDUSTRIAL CHEMICALS

Ammonium Carbonate—First hands are holding stocks well in hand at 8¾c. per lb., and quote the market on the basis of 8¾@9c. per lb. Second hands offer odd lots at 8½c.

Arsenic—Prime white powdered material on spot is held firm by leading dealers at 7¼@7½c. per lb. A moderate consuming inquiry is reported, with trading fairly active.

Bichromate of Potash—A few small-lot sales were recorded by resale merchants at 9¾c. per lb. Large quantities were quoted down to 9½c. Business in this product has not shown any appreciable change during the past week.

Bichromate of Soda—Trading is quiet for both export and domestic consumption. Spot goods are quoted at 7¼@7½c. per lb., with a few small resale lots as low as 7⅛c. per lb.

Caustic Potash—Business has been moderate during the interval and several sales were reported at 5¾c. per lb. for 88-92 per cent goods. Shipments were quoted around $5.65 per 100 lb.

Caustic Soda—The export market is being strongly maintained at $3.80@$3.85 per 100 lb., f.a.s. Inquiries have been more abundant during the past week and producers are looking forward to a better volume of business. Domestic quotations remain practically unchanged.

Copper Sulphate—The general condition of this market is exceedingly firm, with only a few odd lots available. The demand is very active for spot and near futures, with prices for standard large crystals ranging around 6@6¼c. per lb.

Fluoride of Soda—The market has recorded an advance of 1c. per lb. Leading factors report sales of small quantites to the consuming trade at 10@10½c. per lb. Demand is fairly active.

Nitrite of Soda—Most trading has been done on a small quantity basis, with resale merchants quoting 8¼@8½c. per lb. for imported material. Domestic prices are held around 9c. per lb.

Prussiate of Soda—Demand has eased off considerably and spot prices were much lower. Imported goods was quoted as low as 20½c. per lb. with the prevailing figure at 21½c. per lb. Recent arrivals have had a detrimental effect on the spot market.

Soda Ash—The market for this commodity is reported quiet by leading factors. Light 58 per cent, in single bags, is quoted at $1.80 per 100 lb. in carload lots on spot. Contracts remain unchanged.

Sodium Acetate—The lowest price for spot material is around 5½c. per lb. The demand has shown considerable improvement during the past few weeks and producers report a temporary shortage of spot supplies.

COAL-TAR PRODUCTS

Benzene—Resale material is exceedingly scarce, with a few light offerings of the 90 per cent held around 35@40c. per gal. Producers continue to quote contracts of the 90 per cent at 28@32c. per gal. and the pure at 30@35c.

Cresylic Acid—Resale 97-99 per cent material on spot is quoted as high as 65c. per gal. Several sales were recorded at this level. The general condition of this market is very firm, with offerings limited. Producers are quoting 56@58c. per gal. for the 97-99 per cent and 51@53c. for the 95 per cent, dark, f.o.b. works.

Alpha Naphthol—The refined material sold at $1.10@$1.15 per lb. during the past week. Small lots seemed to feature the market. Technical goods remained dormant, with sellers asking $1@$1.05 per lb.

Beta Naphthol—There has been no improvement in the market for the technical variety and the general condition is very irregulaar. Spot material is quoted around 23c. per lb.

The Iron and Steel Market

PITTSBURGH, June 16, 1922.

The general iron and steel situation underwent no particular change in the past week. Pressure upon the mills for deliveries may have increased a trifle, while the volume of sales and purchases probably decreased slightly. The steel market is not especially active, from a tonnage standpoint, not nearly as active as in April.

The urgency of steel buyers for deliveries is probably not a measure of their immediate requirements, but rather represents anxiety lest something occur to prevent shipment later, such as a decrease in steel production due to the coal strike. There is no evidence that any consumers of steel are really short of steel or are having their operations restricted on this account.

HAS THERE BEEN AN ACCUMULATION OF STOCKS?

As to the general position of the steel market, its strength and its prospects for the nearby future, the discussion still centers around the question of how much steel buyers have accumulated. Production in the past 3½ months almost equals production in the 6 months preceding. It is pointed out that part of the so-called accumulation of stock is in steel which buyers have gathered together for construction and other work, in accordance with ordinary practice, and this prevents the steel from being considered speculative, or as accumulated merely because there is a coal strike.

While the condition can be explained and defended, the bare fact remains that the steel market is more or less on the defensive—that is, there is a call, admitted to be reasonable, for an explanation of why the market is as strong as it is. Steel ingot production at the present rate, about 39,000,000 tons a year, is 30 per cent in excess of the average rate in the two largest tonnage years before the war, 1912 and 1913, and 55 per cent above the output in the next best year, 1910, yet one could scarcely say that the surface indications are that steel is being actually consumed in the same tonnage as in those years.

THE STEEL MARKET

The steel market has been gradually growing quieter as to tonnage turnover. The trend can be attributed to the increasing unwillingness of mills to obligate themselves farther, as they are well sold up now and the coal strike is not ended, to the disposition of buyers not to commit themselves as far ahead as they used to do, and to the approach of the usually dull midsummer period.

Prices are very firm all along the line, and if prices do not show a general advancing tendency there is at least a little more disposition for early deliveries to command premiums, and there is an advancing tendency in manufactured steel products, such as bolts, rivets, spikes, cold-finished bars, etc., attributed to the higher prices now ruling for the raw materials involved.

The market is quotable as follows: Bars, shapes and plates, 1.60@1.80c.; hoops and bands, 2.25@2.40c.; blue and annealed sheets, 2.40@2.50c.; black sheets, 3.15@3.30c.; galvanized sheets, 4.15@4.30c.; automobile sheets, 4.50@4.75c.; tin plate, $4.75; nails, $2.40@$2.50; standard steel pipe, 71 per cent basing discount.

PIG IRON AND ORE PRICES

The pig iron market continues very dull, and is not quotably changed, as follows: Bessemer and basic, $25; foundry, $24@$25 f.o.b. valley furnaces.

Lake Superior iron ore prices for the 1922 season have been developed at 50c. decline from the 1921 and 1919 prices, or $1.50 under the 1920 schedule. The new prices, f.o.b. Lake Erie docks, are: Old range bessemer, $5.95; old range non-bessemer, $5.20; Mesabi bessemer, $5.70; Mesabi non-bessemer, $5.05. Approximately half the reduction from last year is borne directly by the ore producers, the remainder being in reduced transportation cost. The transportation tax has been off since the beginning of the year, involving a saving of about 5c. a ton. Rail rates from mine to dock have been reduced 10 per cent, equal to 10c. on Vermilion and Mesabi ores, the net lake vessel rate is down 10c. and the Lake Erie dock charge, added to the vessel rate, is down 1c., making the total lake rate 70c. plus 13c., or 83c. This brings the ore to the market prices being in essence at the rail of the vessel, and then there is a reduction in the dock charge from rail to car from 8½c. to 8c., a direct saving to the ore buyer in addition to the 10 per cent reduction in rail rates from Lake Erie which went into effect June 15.

The Chicago Market

CHICAGO, Ill., June 15, 1922.

Firmness characterizes the industrial chemical market, even though sales show no particular increase in volume. Demand continues only routine, although buyers display a little more confidence in the market. Stocks are not generally heavy and it is difficult to locate any supplies at all of some items. Prices are maintained in nearly every direction, even the small broker being reluctant to cut his schedule. Imported material is very firm, with arrivals lighter than usual.

GENERAL CHEMICALS

The alkali market is unchanged, with the movement of supplies fairly active. *Caustic soda* is firm at $3.85@$3.95 per 100 lb. for the solid and $4.35@$4.50 for the ground or flake. *Caustic potash* continued firm, with small lots of the 88-92 per cent material offered at 6¾c. per lb. *Soda ash* is reported to be moving well at $2.20@$2.30 per 100 lb. for the 58 per cent material in cooperage.

Alums are in an easy position, although holders maintained their schedules. *Ammonia alum* is available at 3½@4c. per lb. for the lump and 4@4½c. for the powdered. *Potash alum* is in light demand and lacks quotable change. The lump is quoted at 4½c. per lb. and the powdered at 5½c., the latter grade moving in a somewhat better volume. Barium compounds, while very firm, are in a somewhat easier position. Small lots of *barium chloride* are available at $110@$120 per ton. *Copper sulphate* continues exceedingly firm, with spot stocks light. Small lots were quoted at 6@6½c. per lb. There is a small demand for ammonium carbonate and the lump is available at 13@13½c. per lb. *Sal ammoniac* is moving in a routine way at 7¾@8c. per lb. for the white granular. The lump sal ammoniac was firm at 17@18c. per lb. *White arsenic* is somewhat easier at 8c. per lb. *Carbon bisulphide* is moving slowly at 7@7½c. per lb. for drums. *Carbon tetrachloride* is enjoying a somewhat better demand and is quoted at 10c. per lb. in large drums.

There is little or no change on bichromates, the market presenting an easy appearance. *Potash bichromate* is quoted at 11¾c. in single-cask lots and the *soda* in similar quantities at 9c. *Potash permanganate* is easy, with U.S.P. material available at 16c. per lb. The prussiates continue very firm and scarce, with prices higher on both kinds. *Yellow prussiate of potash* is quite scarce and only small or medium lots can be located at 34@36c. per lb. The *red* remains off of the market, with nothing in sight for future delivery. *Potash chlorate* is moving slowly at 8c. per lb. for the powdered and 9@10c. for the crystals. *Rochelle salts* are in an easy position and imported powder is available at 20c. per lb. *Hyposulphite of soda* is dull at $3.85 per 100 lb. for the pea crystals in barrels.

LINSEED OIL

Linseed oil is moving a great deal more freely and the outlook is brighter. Single drums of the boiled oil are quoted at 98c. per gal and the raw in similar lots at 96c.

NAVAL STORES

Turpentine is none too plentiful, and the local market was very firm. A prominent factor in the market predicts higher prices with increasing scarcity. A good movement is reported at $1.06 per gal., basis single drums. *Rosins* were in a position similar to turpentine and are reported to be moving freely. The WW grade is quoted in less than carlots at $9 per 280 lb.

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$1.00 — $1 05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.14 — .16
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.30
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.80 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.50 — .55
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.50 — .55
Beta-naphthol, tech	lb.	.23 — .26
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.56 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.51 — .58
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.65 — .70
Dimethylaniline	lb.	.36 — .38
Di nitrobenzene	lb.	.22 — .25
Dinitroclorbenzene	lb.	.22 — .24
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Dipnenylamine	lb.	.59 — .65
H-acid	lb.	.80 — .95
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.09 — .11
Monoethylaniline	lb.	1.00 — 1.20
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½— .07
Naphthalene, balls	lb.	.08 — .08
Naphthionate of soda	lb.	.58 — .65
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17
N-W acid	lb.	1.15 — 1.30
Ortho-amidophenol	lb.	.40 — 2.50
Ortho-dichlor-benzene	lb.	2.15 — .20
Ortho-nitro-phenol	lb.	.70 — .75

Ortho-nitro-toluene	lb.	$0 10 —	$0.13
Ortho-toluidine	lb.	.14 —	.18
Para-amidophenol, base	lb.	1 25 —	1.30
Para-amidophenol, HCl	lb.	1.30 —	1.35
Para-dichlorbenzene	lb.	.17 —	20
Paranitroaniline	lb.	.72 —	.75
Para-nitrotoluene	lb.	.55 —	.65
Para-phenylenediamine	lb.	1.55 —	1 60
Para-toluidine	lb.	.90 —	1.00
Phthalic anhydride	lb.	.35 —	.38
Phenol, U. S. P., drums	lb.	.14 —	15
Pyridine	gal.	1 75 —	2 75
Resorcinol, technical	lb.	1.30 —	1 35
Resorcinol, pure	lb.	1.75 —	1.80
R-salt	lb.	.60 —	.70
Salicylic acid, tech., in bbls	lb.	.25 —	.25½
Salicylic acid, U. S. P	lb.	.26 —	.26½
Solvent naphtha, water-white, in drums, 100 gal	gal.	.27 —	.32
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.14 —	.18
Sulphanilic acid, crude	lb.	.24 —	.26
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	28
Toluene, in drums	gal.	.30 —	35
Xylidines, drums, 100 gal	lb.	.40 —	.45

Industrial

Financial, Construction and Manufacturers' News

Industrial Developments

GLASS—The United States Glass Co., Tiffin, O., has fired a second furnace at its plant, increasing the output from 52 to 80 per cent of normal. The works have been placed on full time operating basis, in different departments, giving employment to about 400 men.

The Interstate Window Glass Co., Smethport, Pa., is arranging for the early resumption of operations at its local plant, following a curtailment for some time past.

Following the refusal of a request from operatives for a wage increase, the Consolidated Window Glass Co., Mount Jewett, Pa., has closed its local plant until further notice.

CERAMIC—The Finzer Brothers Clay Co., Sugarcreek, O., manufacturer of face brick and kindred products, is increasing operations at its plant. During the month of May the company made a record output comprising 137 carloads of material, aggregating 1,305,000 bricks.

The Fords Porcelain Works, Perth Amboy, N. J., manufacturer of sanitary ware, is running full at its two local plants, as well as factory at Fords, near Perth Amboy.

RUBBER—The Republic Rubber Corp., Youngstown, O., is increasing production in its mechanical rubber goods department. The Canton, O., works is running on an advanced working schedule, with output averaging 1,500 automobile tires daily.

The Burdick Tire & Rubber Co., Noblesville, Ind., will commence operations at its local plant in July. The works has been completed for a number of months, but has been kept idle until conditions warranted manufacture. The plant has a capacity of 5,000 tires a day, and it is expected to develop this output at an early date. Employment will be given to about 100 men for initial production.

All plants at Akron, O., devoted to the manufacture of mechanical rubber goods, have been placed on a capacity basis with regular operating forces.

The Howe Rubber Corp., New Brunswick, N. J., is increasing operations at its plant in the line of automobile tires. Sales during the month of May were the largest in the history of the company.

The McGraw Tire & Rubber Co., New York, N. Y., has advanced production at its plant to 2,200 casings and 1,500 inner tubes per day. It is expected to make further increase in this output at an early date.

IRON AND STEEL—The Carnegie Steel Co. is arranging for the resumption of operations at six additional open-hearth furnaces and one blast furnace at its Sharon, Pa., plant, bringing production up to close to normal, or full capacity basis. About 1,000 men will be added to the working force.

The United Alloy Steel Corp. has resumed operations at the plant of the Canton Sheet Steel Co., Canton, O., recently acquired, placing four mills in service. Other mills and departments will be reopened at an early date. It is expected to employ a regular working quota of 1,800 men.

The Youngstown Sheet & Tube Co., Youngstown, O., is making ready for operations at its Hubbard plant, which has been idle for some time past. It is said that both blast furnaces will be blown in as soon as the coal supply improves.

The British Empire Steel Corp. is increasing operations at its plant at Sydney, N. S., giving employment to 1,900 men as against a working force of 1,200 on May 1. Additions will be made to this number in the near future.

The Wheeling Steel Corp., Wheeling, W. Va., has reopened the sheet mill at the plant of its Whitaker-Glessner division, Martin's Ferry, O., following a shutdown since the spring of 1921. It is expected to reach the full working quota of 800 men in the near future. The company has advanced the wages of all hourly workers at its different plants at Steubenville, Beech Bottom and Martin's Ferry about 10 per cent.

The National Tube Co., Lorain, O., has increased production to about 80 per cent of capacity at its local plant, which, due to works expansion, exceeds regular production during the pre-war period.

The Eastern Steel Co. is making repairs to the machinery in the blooming mill at its Pottsville, Pa., works, and plans to place the unit in service at an early date. Work will be resumed at the 28-in. mill at the same time.

The Republic Iron & Steel Co. is arranging for the resumption of operations at its rerolling bar mill at Moline, Ill., after a shutdown since early in 1921.

MISCELLANEOUS—The Glidden Co., Cleveland, O., manufacturer of paints, varnishes, etc., is running its five plants on a full-time capacity basis, with 24-hour working schedule.

The Bartlesville Zinc Co., Bartlesville, Okla., is arranging for the resumption of operations at its Blackwell, Okla., smelting plant, following a suspension since last January. Employment will be given to about 400 men.

The Alabama By-Products Corp., Birmingham, Ala., is operating at full capacity and has plans under way for the early erection of twenty-five additional Koppers coke ovens to increase the output by about 50 per cent.

The International Nickel Co., New York, N. Y., has resumed operations at its Port Colborne, Ont., refining plant, after a shutdown for a number of months past. Production at the smelting plant at the works will be deferred for the present.

The United States Cast Iron Pipe Co. has advanced production to about 80 per cent of capacity at its plants at Bessemer and Anniston, Ala., and Chattanooga, Tenn.

The American Smelting & Refining Co. is increasing production at its Perth Amboy, N. J., plant. The working force has been advanced to close to 1,000 men, and further additions will be made at an early date.

Construction and Operation

Alabama

LA PINE — The A. E. Davis Permanent Ink Co. has recently organized under Delaware laws, with capital of $100,000, and is arranging for the establishment of a local plant for the manufacture of ink products, and is making inquiries for equipment, including ink-mixing machines, with capacity of about 75 gal. each. A. E. Davis, Sellers, Ark., is president; and T. A. Bullard, La Pine, general manager.

California

RICHMOND—James Hyslop has leased the local plant of the Coast Brick Co., and will operate the works for the manufacture of glazed and colored tile, and other burned clay products.

LOS ANGELES—Water-softening equipment, air compressors, cooling coils, brine tank, pumping machinery, etc., will be installed in the new plant to be constructed by the Mutual Dairy Co., Maomi and Walnut Sts. Clifford A. Truesdell, Jr., Purington & Newton, 303-7 San Fernando Bldg., associated engineers, are preparing plans.

Florida

MIAMI—The Tropical Fruit Conserving Co., 1444 West Miami Ave., will commence the immediate erection of a new 1-story plant, 75x180 ft., for the manufacture of coconut sirup and kindred specialties. The installation will include pressure cookers, aluminum vats, mixing machinery, etc. Samuel V. Aston is general manager.

GAINESVILLE—The Vego-Hair Mfg. Co., manufacturer of fiber products, is arranging for the rebuilding of the portion of its plant recently destroyed by fire, to comprise three 1-story buildings, each about 30x60 ft. A. H. Selle is general manager.

Illinois

CHICAGO—A 1-story foundry, 60x100 ft., to cost close to $50,000, will be constructed by the Chicago Hardware Foundry Co., 546 West Washington Blvd., at its plant at North Chicago.

CHICAGO—The Chicago Pottery Co., 1924 Clybourn Ave., has filed plans and commenced excavations for the erection of its proposed 2-story addition, 113x190 ft. Contract has been let to Bulley & Andrews, 25 North Dearborn St. L. E. Russell, 25 North Dearborn St., is architect.

LITCHFIELD—The City Council will call for bids about July 15, for the construction of a new filtration plant in connection with improvements in the waterworks system, estimated to cost about $300,000. The Pierce, Greeley & Hanson Engineering Co., 39 South Adams St., Chicago, is engineer.

Indiana

NOBLESVILLE—The New Process Steel Co. is completing construction work on its new local plant, and plans to have the works ready for operation early in July. Employment will be given to about 100 men for initial operations.

Kansas

LEAVENWORTH—The Great Western Stove Co. will build a 2-story and basement addition to its plant at 2nd and Choctaw Sts., to be equipped as an enameling department. W. R. and M. K. Foth, Leavenworth, are architects.

Louisiana

NEW ORLEANS—The Baldwin Petrinite Roofing Tile Co., manufacturer of composition roofing tiles and kindred products, is planning for the installation of additional machinery at its new local plant. Enos Baldwin is general manager.

Maine

TOPSHAM—The Pejepscot Paper Co., operating mills at Topsham, Pejepscot, Lisbon Falls and Bowdoin, Me., for the manufacture of newsprint, pulp, etc., has preliminary plans under way for extensions and improvements for considerable increase in capacity. The work is estimated to cost close to $1,000,000. Edgar Rickard is president, and Fred C. Clark, vice-president and general manager. The company is a subsidiary of the International Development Co.

Massachusetts

MARLBORO — The Dennison Mfg. Co., Framingham, has construction under way on its proposed new local plant for the manufacture of paper specialties, and plans to occupy the structure at the earliest date. It will be 4-story, reinforced-concrete, 70x300 ft., and estimated to cost close to $100,000, including machinery.

Michigan

FLAT ROCK—The Ford Motor Co., Highland Park, has plans in progress for the erection of a new local 1- and 2-story plant at Flat Rock, for the manufacture of glass products, including windshield glass, etc., for Ford automobiles. It is estimated to cost close to $1,000,000, including machinery. Albert Kahn, 1,000 Marquette Bldg., Detroit, is architect.

KALAMAZOO—The Kalamazoo Vegetable Parchment Co., manufacturer of parchment papers, is taking bids on a general contract for the erection of a 2-story plant addition, estimated to cost close to $400,000, including machinery. Billingham & Cobb, Press Bldg., Kalamazoo, are architects. J. Kindleberger is president and general manager.

KALAMAZOO — The Birmingham & Prosser Co., paper products, will construct a new building at its works, 54x166 ft., to cost about $75,000.

Missouri

POPLAR BLUFF—W. S. Hooper, president of the Ozark Ore & Mfg. Co., is at the head of a project to construct and operate a plant near St. Louis, for the manufacture of general chinaware products, estimated to cost in excess of $250,000, including machinery. It is said that a company will be organized to operate the proposed plant.

KANSAS CITY—The Standard Foundry & Mfg. Co., 204 Security Bldg., recently organized, will soon commence the erection of a new 1-story foundry, 90x120 ft., for

the manufacture of a general line of castings. W. H. Simpson is president, and J. B. Harden, secretary and treasurer.

New Jersey

TRENTON—The Unitco Pottery Co., Frazier St., will make extensions and improvements in the kiln department at its plant.

BAYONNE—The chemical laboratory at the plant of the Nucoa Butter Co., Ave. A and 4th St. was damaged by fire, caused by an explosion, June 8. An official estimate of loss has not been made.

Ohio

GOSHEN—S. P. Myers and S. O. McFall, officials of the Uhrichsville (Ohio) Sewer Pipe Co., have acquired the partly completed plant of the H. C. Schneider Sewer Pipe Co., Goshen, designed for the manufacture of vitrified sewer pipe, and adjoining clay properties. The new owners will organize a company to operate the plant, and purpose to complete the final plant units at an early date. The property was purchased for a consideration said to be $146,000.

AKRON—The International Lead Co., a subsidiary of the Anaconda Copper Co., 25 Broadway, New York, N. Y., is investigating local sites with view to the erection of a new plant for the manufacture of zinc oxides and compounds used in the production of rubber products. The proposed works will consist of a number of buildings, estimated to cost close to $1,000,000, including machinery. William Wraith is president.

Pennsylvania

PHILADELPHIA — The Philadelphia Paper Mfg. Co., River Rd., has broken ground for the erection of a new 1-story plant, 120x270 ft., at Umbria, Nixon and Founton Sts., estimated to cost about $60,000. The Hughes-Foulkrod Co., 1201 Chestnut St., has the construction contract. John Jacobs, Jr., is president.

PITTSBURGH—The Young Paper Mfg. Co., 34th St. and the Allegheny Valley Railroad, manufacturer of prepared roofing papers, etc., has preliminary plans under way for the rebuilding of the portion of its plant destroyed by fire, June 8, with loss approximating $100,000, including equipment. The same fire also destroyed a section of the foundry of the Pittsburgh Malleable Iron Co., 34th and Smallman Sts., with loss of about $40,000.

PHILADELPHIA—The Grasselli Chemical Co., 908 Chestnut St., has leased the 3-story building at 909 Sansom St., and will equip the structure for general operating service. Headquarters of the company are in the Guardian Bldg., Cleveland, O.

MARCUS HOOK—The Sun Co., Finance Bldg., Philadelphia, Pa., has commenced the rebuilding of the grease-manufacturing plant at its oil refinery, Marcus Hook, recently destroyed by fire, with loss approximating $60,000, including equipment. The new building will be 75x168 ft.

PHILADELPHIA—The National Ammonia Co. of Pennsylvania, Van Kirk St., has filed plans for the construction of a new building at its plant, to cost about $30,000. The erection contract has been let to E. E. Hollenbeck, Inc., 1804 Brandywine St.

PHILADELPHIA — The Wittman-Moriarty Co., 4th and Vine Sts., manufacturer of leather products, has construction under way and plans for the early occupancy of the new 1- and 2-story addition to its tannery at Ontario and C Sts., estimated to cost about $75,000. J. P. Wittman is president and treasurer.

PHILADELPHIA — The Hurlock Brothers Co., 3436 Market St., manufacturer of cardboard specialties and kindred products, has work under way on an addition to its plant, to cost about $10,000.

South Carolina

GREENVILLE—The Boll-We-Go Mfg. Co., recently organized, has plans under way for the establishment of a local plant for the manufacture of chemical compound products. Homer L. Todd is president.

Tennessee

COPPERHILL—The Tennessee Copper Co., 61 Broadway, New York, N. Y., has work under way on plant additions, including flotation expansion, with capacity of about 500 tons. J. N. Houser is general manager.

Texas

EL PASO—The J. M. Booth Chemical Co., manufacturer of sal soda and kindred products, has preliminary plans under way for the construction of an addition to its plant. Joseph M. Booth is president.

DALLAS—The Lignite Industries Corp., St. Paul, Minn., has organized a subsidiary company to be known as the Texas Lignite Co., for the construction and operation of a series of six plants in this state, to be located at Dallas, Fort Worth, Galveston, Houston, Greenville and one other point to be selected. Plans are under way for the initial works for the production of pressed briquets, with large chemical byproduct plant to be used for ammonia, carbolic acid, lubricating oil and paraffin manufacture. The entire project is estimated to cost close to $200,000, including equipment. Carl Jaeger is president and chemical engineer.

DALLAS—The Dallas Gas Co. has preliminary plans under consideration for extensions and improvements in its plant and system, to cost in excess of $300,000.

Virginia

RICHMOND—The Fibre Board Container Co., 3200 Williamsburg Ave., has plans under way for extensions in its plant, to double, approximately, the present output. D. J. Donati is president.

BUENA VISTA—The United Chemical Products Co., Chamber of Commerce Bldg., Pittsburgh, Pa., is taking bids for the construction of a new local plant, 1-story, 41x145 ft., estimated to cost close to $50,000. F. B. Doane is company engineer.

HEATHSVILLE—The Cherrystone Fish Oil Co., recently organized, has acquired the plant of the Cherrystone Oil & Guano Co., and will operate the works for the production of commercial fish-oil products. Improvements are being considered. T. H. Fallin, Coan, Va., is president; and A. J. Lewis, vice-president.

West Virginia

PIEDMONT—The Potomac Fire Brick Co. has commenced the installation of new machinery at its plant for considerable increased capacity.

WELLSBURG—The Hammond Bag & Paper Co., recently organized with a capital of $500,000, has plans in preparation for the construction of a new 1-story plant, 125x500 ft., for the manufacture of paper products. T. H. Hammond is president; and D. A. Burt vice-president.

LANSING—The Shawner Construction Co. has commenced the erection of a new 1-story plant on local site, for the manufacture of cement bricks, blocks and kindred products. A list of equipment for installation is being arranged. J. A. Ellison is general manager.

Canada

TODMORDEN, ONT.—The Don Valley Paper Co., Ltd., Don Mills section, is planning for the rebuilding of the portion of its plant, destroyed by fire, May 31, with loss approximating $100,000, including equipment.

New Companies

THE BERKSHIRE COATED PAPER CO., Great Barrington, Mass., has been incorporated with a capital of $75,000, to manufacture paper products. Jeremiah H. Whitehouse, 77 Firglade Ave., Springfield, Mass., is president and treasurer.

THE S. & S. CHEMICAL CO., care of William Charlton, 404 Guarantee Trust Bldg., Atlantic City, N. J., representative, has been incorporated under state laws with capital of $50,000, to manufacture chemicals, chemical byproducts, etc. The incorporators are Lionel C. Schener, Arthur G. Walker and M. H. Sachs, all of Atlantic City.

THE AERO RUBBER PRODUCTS CORP., care of B. E. Reardon, Yonkers, N. Y., representative, has been incorporated under state laws with capital of $150,000, to manufacture rubber products. The incorporators are I. R. Davies, J. P. and I. Todd, all of Yonkers.

THE ATLAS ASBESTOS CO., Norristown, Pa., has been incorporated with a capital of $25,000, to manufacture asbestos products. J. C. Johnston, Norristown, is treasurer.

THE LATHROAL SOAP CO., Tallahassee, Fla., has been incorporated with a capital of $10,000, to manufacture soaps and affiliated products. The incorporators are J. A. O'Berry and Robert Hancock, both of Tallahassee.

THE FLEXIBLE CORK PRODUCTS CO., Jersey City, N. J., has been incorporated with a capital of 7,000 shares of stock, no par value, to manufacture cork specialties. The incorporators are John C. and Grier P. Manning, and John P. Taggart, 737 Communipaw Ave., Jersey City.

THE REIBER-ZIEGLER CORP., care of Louis Levy, 277 Broadway, New York, N. Y., representative, has been incorporated under state laws with capital of $20,000, to manufacture chemicals, paints, etc. The incorporators are M. and S. A. Reiber, and E. D. Ziegler, all of New York.

THE MILLION DOLLAR CHEMICAL CO., Cleveland, O., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are Joseph H. Crowley and Sidney N. Weitz, Tenth Floor, B. of L. E. Bldg., Cleveland.

THE SOUTHWESTERN OIL PRODUCING CORP., care of Arley B. Magee, Dover, Del., has been incorporated under state laws with capital of $9,000,000, to manufacture petroleum products.

THE ELECTRO-MOULDED PRODUCTS CORP., Arlington, Mass., has been incorporated with a capital of 50 shares of stock, no par value, to manufacture composition and molded specialties. Charles E. Clarke is president; and Laurence M. Pitman, 1117 Appleton St., Arlington, treasurer.

THE P. & M. BRICK MFG. CO., care of A. Simmons, New Rochelle, N. Y., attorney, representative, has been incorporated under state laws with capital of $20,000, to manufacture brick, with plant at Saugerties, N. Y. The incorporators are W. Picker, J. and R. Malakoff.

THE CHICAGO FANCY LEATHER SPECIALTIES MFG. CO., 600 Blue Island Ave., Chicago, Ill., has been chartered under state laws to manufacture leather products. The incorporators are Soren D. Mortensen, George L. Frebn and George J. Prehn.

THE KAY OIL CO., Blackwell, Okla., has been incorporated with a capital of $75,000, to manufacture petroleum products. The incorporators are W. M. Vickery, David Schonwald and H. S. Curley, all of Blackwell.

THE TEXTILE RUBBER CO., Boston, Mass., has been incorporated with a capital of $50,000, to manufacture rubber products. John E. Shannon is president; and Charles V. McManus, Lynn, Mass., treasurer and representative.

THE ALUMINUM CONTAINER CORP., care of Piper & Pendergast, Fulton, N. Y., representatives has been incorporated under state laws with a capital of $200,000, to manufacture aluminum products. The incorporators are F. A. Stafford, S. M. Stevenson and C. Jensvold, all of Fulton.

THE PERUVIAN COMPOSITION PRODUCTS CORP., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del., representative, has been incorporated with a capital of $1,250,000, to manufacture brass, steel and affiliated products.

THE LIMESTONE PRODUCTS CO., Menominee, Mich., has been incorporated with a capital of $25,000, to manufacture lime products. The incorporators are N. S. Meyers, H. J. Grami and E. P. Smith, 312 Main St., Menominee.

THE LAKE SHORE RUBBER CO., Newark, N. J., has been incorporated with a capital of $150,000, to manufacture rubber products. The incorporators are George P. Labie, Frederick G. Kautz and Henry Pomerehne, 20 Clinton St., Newark.

THE WILLMOTT OIL CORP., Okmulgee, Okla., has been incorporated with a capital of $400,000, to manufacture petroleum products. The incorporators are C. S. Willmott, John Caruthers and Joseph M. James, all of Okmulgee.

THE UTAH POTASH CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., has been incorporated under state laws with capital of $8,200,000, to manufacture potash products, with plant in the Utah potash fields.

THE AARD ASBESTOS COVERING CO., 2644 Wellington Ave., Chicago, Ill., has been incorporated with a nominal capital of $1,500, to manufacture asbestos specialties. The incorporators are Earl J. and Lester J. Mulligan, and M. J. Black.

THE MARTIN MINERAL PRODUCTS CO., Newark, N. J., has been incorporated with a capital of $125,000, to manufacture cleansers, chemical compounds, etc. The incorporators are William S. Wilde, Otto G. Mathede and Samuel C. Martin, 31 Clinton Street, Newark.

THE SEYD FERTILIZER & CHEMICAL CO., Boston, Mass., has filed notice of organization to manufacture chemical specialties, etc. The company is headed by R. Bryce Gemmel and Harold H. Seyd, P. O. Box 1936, Boston.

THE KENTUCKY-INDIANA OIL CORP., Richmond, Ind., has been incorporated with a capital of $100,000, to manufacture petro-

leum products. The incorporators are George N. Snyder, S. G. Smelser, Richmond; and Z. O. Avery, Lexington, Ky. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del.

THE HOLLAND OIL CO., Jamestown, N. Y., has been incorporated with a capital of $50,000, to manufacture refined oil products. The incorporators are C. A. Johnson, J. Sampson and A. W. Beckstrom, all of Jamestown. The company is represented by C. S. Grover, Jamestown, N. Y.

THE HOLLAND MAGNETO PRODUCTS CO., 337 West 12th St., Holland, Mich., has been incorporated with a capital of $25,000, to manufacture magnesite products, hollow tile and kindred specialties. The incorporators are Harry E. and Cecil Huntley, and William E. Dunn.

THE BRYER METALLIC POLISH CO., Boston, Mass., has filed notice of organization to manufacture polishes and kindred products. The company is headed by George Bryer, 97 Sudbury St., Boston.

THE LIFE SERVICE CHEMICAL LABORATORIES, INC., care of the United States Corporation Co., Pennsylvania Bldg., Philadelphia, Pa., representative, has been incorporated under Delaware laws with capital of $100,000, to manufacture chemical products, with headquarters at Philadelphia. The incorporators are Harold Colson and Harry R. Lee, Philadelphia.

THE MYERS LEHMAN CO., New York, N. Y., care of Harry Kutscher, 50 Broad St., representative, has been incorporated under state laws to manufacture paints, oils, etc. The incorporators are A. and E. Lehman, and H. F. Myers.

THE STOVER RUBBER CO., 1409 South Michigan Ave., Chicago, Ill., has been incorporated with a capital of 500 shares of stock, no par value, to manufacture rubber products. The incorporators are M. C. Suhr, E. E. Levy and I. K. Stover.

THE NEWARK ASBESTOS PRODUCTS CO., Newark, N. J., has been incorporated with a capital of $100,000, to manufacture asbestos specialties. The incorporators are Henry C. Schnening, Walter A. Cross and Myer N. Semel, 29 Essex St., Newark.

THE G. B. HAYNES OIL CO., Monroe, La., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $250,000, to manufacture petroleum products.

THE LO-CO-MO OIL CO., 130 North Wells St., Chicago, Ill., has been incorporated with a capital of $10,000, to manufacture oil products. The incorporators are A. S. and Jean D. Salkey, and B. E. Langan.

RHODIA, INC., New York, N. Y., care of S. V. Ryan, Albany, N. Y., representative, has been incorporated with a capital of $5,000, to manufacture essential oils and affiliated products. The incorporators are A. F. Von Bernuth, J. H. Purdy, Jr., and C. A. Marshall, New York.

THE MADISON PAPER CORP., care of D. E. Keller, 51 Chambers St., New York, N. Y., has been incorporated under state laws with capital of $20,000, to manufacture paper specialties. The incorporators are E. M. Miller, J. Orozoco and M. S. Somers, all of New York.

THE PALM BEACH OIL CO., West Palm Beach, Fla., has been incorporated with a capital of $10,000, to manufacture oil products. B. D. Hartsfield is president; H. P. Jones, vice-president, and M. M. May, secretary, all of West Palm Beach.

THE CLIFTWOOD POTTERIES, INC., Morton, Ill., care of Evans, Galbraith, Sutherland & Evans, Lehmann Bldg., Peoria, Ill., has been incorporated with a capital of $60,000, to manufacture pottery and affiliated burned clay products. The incorporators are Matthew, John W. and Carl M. Rapp, all of Morton.

THE PREMAX PETROLEUM CORP., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., has been incorporated under state laws with a capital of $100,000, to manufacture petroleum products.

THE WOOD FIBRE PRODUCTS MFG. CO., New York, N. Y., care of Geza Eichhorn, 309 Broadway, representative, has been incorporated with a capital of $20,000, to manufacture fiber products. The incorporators are A. Horowitz and E. Rosenbaum.

THE TIGER OIL CO., Eldorado, Ill., has been incorporated with a capital of $30,000, to manufacture oil products. The incorporators are E. B. Brouilet, John A. Erwood and Samuel W. Latham, Eldorado. The latter is representative for the company.

THE LIBERTY CORK TILE CO., care of R. Packet, 2494 Morris Ave., New York, N. Y., representative, has been incorporated under state laws with capital of $100,000, to manufacture cork products. The incorporators are M. Rose and W. W. Meuer. Headquarters will be in Brooklyn, N. Y.

THE HY-TEST REFINING CO., Pittsburgh, Pa., represented by Charles W. Frankel, 415-19 Bakewell Bldg., is being organized under state laws to manufacture refined oil products. The company is headed by Marshall J. Vernet, I. T. Weill and Frank W. Besselman, all of Pittsburgh.

THE AMERICAN SHELLAC CO., New York, N. Y., care of M. J. Cahn, 200 Fifth Ave., has been incorporated with a capital of $20,000, to manufacture shellacs, varnishes, etc. The incorporators are J. Rosen and H. A. Solomon.

Capital Increases, etc.

THE ALLEN TIRE & RUBBER CO., Allentown, Pa., has filed notice of increase in capital from $1,000,000 to $2,500,000, for expansion.

THE JEWETT & SOWERS OIL CO., 20 West Jackson Boulevard, Chicago, Ill., has filed notice of increase in capital from $150,000 to $200,000.

THE HOME OIL CORP., San Antonio, Tex., has filed notice of change of name to the Laurel Refineries, Inc.

The plant and property of the KOSKO CLAY PRODUCTS CO., River Rd., Piscataway (Middlesex County), N. J., manufacturer of hollow tile, etc., will be sold by the receiver Victor W. Main, 147 Market St., Perth Amboy, N. J.

THE GWYNN'S FALLS PAPER CO., Gwynn's Falls, Baltimore, Md., has filed notice of increase in capital to $1,150,000.

Officials of the Beaver Board Companies, Inc., Beaver Rd., Buffalo, N. Y., have organized a subsidiary company, to be known as the BEAVER PRODUCTS CO., INC., to take over the operation of the plants of the parent corporation, for the manufacture of composition board specialties. A bond issue of $2,000,000 is being sold by the new company for general operations, expansion, etc.

THE CALLAHAN ZINC-LEAD CO., 61 Broadway, New York, N. Y., has increased its capital from 500,000 to 1,000,000 shares of stock, the proceeds to be used for plant extensions and general expansion. John Borg is president.

THE SOUTH PENN OIL CO., 424 Sixth Ave., Pittsburgh, Pa., has acquired the plants and property of the Eddystone Oil Corp., West Virginia, for a consideration said to be about $1,000,000. The property will be operated, and general expansion is planned.

THE MALLINKRODT CHEMICAL WORKS, INC., 3600 North Second St., St. Louis, Mo., is arranging for an increase in capital from $250,000 to $5,000,000, for general expansion. Edward M. Mallinkrodt is president.

THE NATIONAL OIL CO., Jersey City, N. J., has filed an involuntary petition in bankruptcy.

EDWARD ENGELMANN, INC., 37 East Houston, St., New York, N. Y., manufacturer of lithographing and other inks, has made an assignment to Edwin Weinberger, 965 Simpson St., New York.

THE REPUBLIC RUBBER CORP., Youngstown, O., has arranged for a security issue of $1,500,000, the proceeds to be used for general financing, operations, etc.

Arthur J. Stevens, president of the PARSONS PULP & LUMBER CO., Finance Bldg., Philadelphia, Pa., has been appointed receiver for the company. The company is said to have debts totaling $4,000,000, and assets in excess of $5,000,000.

Industrial Notes

The law offices of CHARLES W. HILLS, Chicago, announce that Russell P. Fischer has become associated with them in the practice of patent, trade mark, copyright, unfair competition and corporation law.

THE BUFFALO FOUNDRY & MACHINE CO., Buffalo, N. Y., has recently acquired the coppersmithing business formerly conducted by the W. A. Case & Son Mfg. Co. of Buffalo, including the copper shop equipment. This new department enables the Buffalo Foundry Co. to render a more complete service to customers, as it can now furnish all kinds of copper work, including copper-distilling apparatus, copper evaporators, copper kettles, copper vacuum pans, copper coils, etc., and do a general coppersmithing business either in new work or repairs.

J. M. Kryl, present president of the Kryl Bridge & Crane Works, Chicago, and W. H. Eichelman, until recently chief engineer of the Hamler Boiler & Tank Co. of Chicago, have recently formed a partnership which has been established in Chicago under the name of KRYL & EICHELMAN. Both men are graduate engineers, experienced in fabricating steel plate and structural iron with present facilities for handling water tanks, oil tanks, stacks, process kettles of all kinds for chemical equipment, ornamental iron and structural steel.

THE CONSOLIDATED PRODUCTS CO., New York, dealer in machinery, was the largest purchaser of equipment at the government auction sale at Nitro, W. Va., during the week of May 22. The sale brought a total of over one-half million dollars and the Consolidated company's purchases were in the neighborhood of $100,000, giving it one of the largest dealers' stocks of chemical equipment.

THE COMBUSTION ENGINEERING CORP., New York, announces that A. D. Halporn, who has been associated with the Philadelphia sales staff for some time, is now a member of the New York sales force.

THE PITTSBURGH TESTING LABORATORY announces the opening of a sales office with a complete inspection bureau at 1864 Railway Exchange Bldg., St. Louis, Mo., and the appointment of Colonel N. C. Hoyles as district manager. Colonel Hoyles is a graduate of Queens University and has also taken a post-graduate course at the University of Toronto. He entered the service of this company as an inspector at the Birmingham office; in 1914 was transferred to the Vancouver office; and at the breaking out of war he entered the service of the Canadian Army, serving with the British Pioncer Engineers Corps in France. He received decorations from both the French and British governments, and upon his release from the army in 1919 was appointed assistant sales manager at Cleveland. Since that time he has been consecutively assistant sales manager at New York and manager at Cincinnati, until his appointment to this new position.

THE AMERICAN GAS ASSOCIATION'S headquarters will be located at 342 Madison Ave., New York City, after July 1.

ORTON & STEINBRENNER CO., Chicago, Ill., manufacturer of locomotive cranes, grab buckets and coal crushers, have moved its offices from the 11th to the 19th floor of the Transportation Bldg., 608 South Dearborn St.

Coming Meetings and Events

ALPHA CHI SIGMA fraternity will hold its seventh biennial conclave at the Marquette Hotel, St. Louis Mo., June 22, 23 and 24.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold a joint meeting with the Pacific Division of the Association, on the occasion of the annual meeting of the latter, in Salt Lake City, June 22 to 24.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Pittsburgh, Pa., Sept. 5 to 9.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 21, 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS is holding its summer meeting at Niagara Falls, Canada, June 19 to 22. Headquarters are at the Clifton Hotel.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its nineteenth annual meet-at Bigwin Inn, Bigwin Island, in the Lake of Bays district, Ontario, Canada, on June 21, 22 and 23.

AMERICAN SOCIETY FOR STEEL TREATING will hold its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

ANNUAL SAFETY CONGRESS OF THE NATIONAL SAFETY COUNCIL will be held in Detroit, Mich., Aug. 28-Sept. 2.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY will meet at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

The Cost of Technical Control

AT ONE of the recent technical sessions of the Institute of Metals a paper was read describing the very complete technical control of foundry operations connected with experimental developments on army aircraft. While admitting that such close supervision was unnecessary in commercial foundries working with somewhat standardized methods and common analyses, a question was asked from the floor, "What does technical control in the foundry cost?"

The question might be answered from the autobiography of no less an ironmaster than ANDREW CARNEGIE. He was describing the many difficulties encountered during the early operation of the Lucy furnace—an undertaking they "would have postponed if we had realized its magnitude." Little furnaces could be run by rule of thumb and guess, but not such a monster as the Lucy. Finally he employed a Dr. FRICKE, a German chemist, to assist the manager, and straightway "Lucy furnace became the most profitable branch of our business, because we had almost the entire monopoly of scientific management. It was years after we had taken chemistry to guide us that it was said by the proprietors of some other furnaces that they could not afford to employ a chemist. Had they known the truth then, they would have known that they could not afford to be without one."

Burying the Borax Bugaboo

ALTHOUGH the enemies of American potash probably will continue to echo the borax refrain for some time to come, we are glad to record and give wide publicity to the fact that American potash now meets the standard of purity set by the United States Department of Agriculture. Borax is no longer a deleterious constituent of the American product. In fact for two years the borax content of Searles Lake potash has ranged from 0.27 to 0.5 per cent, comparing favorably with the borax content of sodium nitrate, which is widely used in fertilizing American crops.

We are glad that the Bureau of Soils has seen fit to place its official stamp of approval on American potash, particularly with regard to its borax content, because it was through the investigations of this bureau that borax was found to be the offending element of the domestic product that caused crop injury in Maine and North and South Carolina in 1919. When the producers at Searles Lake had their attention directed to the injurious nature of the borax, they improved their methods of production and eliminated that constituent. For the past two years the Bureau of Soils has analyzed the Searles Lake product with the results given above, and now makes the statement that "under the present method of producing potash at Searles Lake, California, there no longer exists the former danger to crops from the presence of borax in the fertilizer."

This will disarm the propagandist for German potash of one of his favorite arguments against the domestic product. But he will continue to hark back to the old story, and it will be necessary to spread the latest news broadcast in order effectually to bury the borax bugaboo and kill the prejudice that exists in the minds of the farmers. It should be the pleasant duty of every American to spread this news.

Marking Time on Muscle Shoals

TIME was when the controversy over Muscle Shoals waged principally about the question of government ownership and operation. Those were the days of Secretary BAKER and the U. S. Fixed Nitrogen Corporation. Both have since passed into the discard and the stage is held by competing bidders whose fortunes wax and wane almost with each succeeding moon. At the present writing Mr. FORD holds a distinct advantage. The House Committee on Military Affairs has made a majority report recommending that Mr. FORD'S offer to lease the power projects and buy the nitrate plants be accepted. The committee finds that "the Ford proposal was the only proposal worthy of serious consideration," also that it is "the only proposal sufficiently comprehensive in its terms to meet the requirements of . . . the national defense act." Neither does the minority report reject the Ford offer. In fact it would accept it in whole, whereas the majority report approves it only in part and with certain modifications. But there is a third group that has revolted against Mr. FORD and will have none of his proposal. At first there were only two who bolted, but according to last reports there are now eight members of the House who violently denounce the Ford plan.

Aside from the fact that the name of FORD is one to conjure with in industry, it is not difficult to see why Congress is favorably impressed with his offer. The committee finds that "it is the continuing considerations to be performed by Mr. FORD and his company over a long period of about 100 years which gives to his proposal its merit." What are these "continuing considerations"? First, nitrogen preparedness in the form of Nitrate Plant No. 2 maintained in readiness for production, at full capacity, of nitrogen to be used in the manufacture of explosives. This is cited as a contribution to the national defense for the next hundred years. Second, Mr. FORD proposes for his company that "continuously throughout the lease period . . . it will manufacture nitrogen or other commercial fertilizers . . . at Nitrate Plant No. 2," and that "the annual production of these fertilizers shall have a nitrogen content of at least forty thousand tons of fixed nitrogen, which is the present annual capacity of Nitrate Plant

No. 2." Third, the company agrees that its maximum net profit on the manufacture and sale of fertilizers shall not exceed 8 per cent of the annual cost of production. There are numerous other provisions, all of which point to the sincerity of the proposal and add to its attractiveness.

It will be observed, however, that the Ford offer still contemplates a payment of only $5,000,000 for the nitrate plants, and a lease of the power project for one hundred years. So far as the latter is concerned the offer of the Alabama Power Company is vastly superior and more equitable to the United States, being in conformity to the terms of the federal waterpower law. There is no comparable offer for the chemical plants, so that we can merely raise the question whether the sale of property having a war-time cost of $106,000,000 for $5,000,000 is too large a price to pay for the assurance of nitrogen preparedness in Nitrate Plant No. 2 for the next hundred years. The probability is that the price is too great, although the House Committee on Military Affairs is disposed to pay it. The Senate Committee on Agriculture, however, with the characteristic lack of unanimity now prevailing in Congress, gives evidence of sentiment in favor of a policy of government control and operation. In fact Chairman NORRIS has announced that he will introduce a bill creating a government corporation for this purpose.

And so the controversy goes merrily on. The stage has been held successively by one plan after another, each emanating from a source whose interest was dominant at the moment. First the government felt that as a measure of preparedness it should operate the plant. Then the Ordnance Department felt reassured by the commercial developments in nitrogen fixation and was content to urge the retention of Muscle Shoals in standby condition. This was followed by a series of proposals from private interests to buy, lease and operate the plants, and now that these offers have been debated for months the pendulum is about to swing back toward the policy of government ownership and operation. By the time this idea is again debated some new scheme will be brought forward to furnish a subject for speechmaking and discordant opinion. At the present writing it looks as though Mr. FORD might get Muscle Shoals, but that great project may yet go down in history as our most fruitful cause of diverse opinion and abortive legislation.

Potash Propaganda

"PROPAGANDA against the duties on potash is afoot and the farmers in large numbers are writing to their Senators asking that they oppose these duties. Some of those favoring the potash provision in the tariff contend that the German syndicate is back of this propaganda." This statement, taken from some of our recent Washington correspondence, is not in itself very startling, for charges of propaganda and lobbying, especially in connection with the potash tariff, have been all too common. However, we have recently come across some concrete evidence of the propaganda being used by the tariff opponents, and certainly we cannot pass it by without very vigorous protest.

We refer to a most deceptive piece of farm-journal advertising—in this particular case appearing in *The Rural New Yorker* for June 3. It purports to be a stirring appeal to safeguard the vital interests of the American farmer and is published over the name of the "Soil and Crop Service, Potash Syndicate, H. A. Huston, Mgr." Not one reference is made to the German producers and the manager appears to have been extremely careful not to explain, as he did before the Senate Finance Committee last December, that "there is only one potash syndicate, which is the German Potash Syndicate."

The advertisement implies that the "propagandists" of the domestic industry have "bluffed" Congress into believing that the farmers are not opposed to the tariff, or otherwise the representatives of the national farm organization would have been heard at the tariff hearings. As a matter of fact it is generally known in Washington that these organizations, after requesting and being granted almost prohibitive duties on agricultural products, are not in a position to deny moderate protection to other American industries. Mr. HUSTON, however, is most anxious "to look after legislation affecting the farmers' interests." "The only effective way to do this," he says, "is for farmers to write to both of their United States Senators in Washington urging them to see that the 'joker' at the end of paragraph 1,635 be struck out and that potash used in fertilizers remain on the free list, where it has always been." Thus we have an explanation, perhaps, for the increasing volume of Senatorial mail to which our Washington correspondent has referred.

That word "joker," which plays a prominent part in this deception, is an inference which we cannot help but resent. It is an implication of subterfuge and evasion on the part of the domestic industry, which has at all times squarely and openly presented its case before Congress. But these are not all of even the most patent attempts to be misleading! Witness this paragraph:

> During the time when foreign potash could not be obtained, potash sold for more than ten times the prewar or the present prices. Then the American producers, some of whom are known as the "Borax Brigade," had the opportunity of profiteering to the limit and of selling at very high prices potash of an inferior and sometimes injurious kind.

To those domestic producers who have weathered the storm of depression and the recent flood of foreign potash these charges of profiteering are but grimly humorous. However, the insinuation of the inferior quality of American potash is most indignantly resented. Eleswhere in these columns we tell of how the Department of Agriculture has officially interred the borax bugaboo. Isn't it about time to do the same with some other of the potash propagandist's insidious misrepresentations?

Errors in Brinell Testing

ATTENTION was recently called, in these columns, to the consistent discrepancies in Brinell hardness of rivet bars from the same heat reported from two government laboratories—a matter worthy of remark because of the impression that accurate tests for hardness are quite easy to make. Only a few years back hardness was an elusive property to measure. Now, with the Brinell ball test and the scleroscope we think we can define the hardness of metal within fairly close limits.

Therefore it may be useful to call attention to the fact that various laboratories making Brinell hardness tests, particularly on soft materials, may show large variations. Usually the metal is reported as being much too soft. For instance, a well-made uniform bar

of a light alloy was sent successively to several metallurgical laboratories. The correct hardness, as reported by the Bureau of Standards, was 91, using a 10-mm. ball and 500-kg. load. The other returns went as low as 63, and seldom approached within ten units of the true figure. Another similar experiment was described by J. V. EMMONS before the Cleveland Steel Treaters. Results on a piece of steel which was truly 170 Brinell units hard varied from 153 to 175!

Five principal precautions are ordinarily mentioned in literature describing the Brinell test. First, the diameter of the ball should be exactly 10 mm.—but by the method of manufacture, hardened balls are usually more accurate than ordinary micrometers. Second, the impression should be carefully measured—as it can be by low-power microscope and line rule, or micrometer eyepiece, except when a very soft metal flows so badly as to round off the edge of the dent. Third, the hardness of the ball should be correct—but that is of little or no moment when measuring hardness below 200. Fourth, the load should be exactly 3,000 kg. (or 500 kg. for soft metal). Here is where many machines are inaccurate, due to defective packing; but the accuracy of the load should often be checked as closely as a good platform scale or tensile testing machine can weigh. Fifth, the full load should be left on the specimen one minute.

Given these things in close adjustment, a large error can easily be made by increasing the speed of loading. In fact, it is so prolific a source of error that it is strange that the rate of loading has not been definitely limited, either by specification or by the construction of the machine.

Most Brinell machines are arranged so that the load is applied by a hydraulic cylinder, wherein the pressure is pumped up by hand and kept from going above the correct figure by a counterweighted piston or float. This seems an admirable and almost foolproof arrangement. But if the pump handle is worked so vigorously that the counterweight finally jumps up suddenly, it is apparent that the pressure in the cylinder—and therefore the weight on the ball—is momentarily lighter than the limiting load by an amount proportional to the friction of the movable parts and their inertia. With the 500-kg. load limit, this excess is a considerable percentage of the total. Consequently a much larger hole is punched into soft metals than their hardness warrants and an abnormal value is obtained.

Heavy Research
In Copper and Brass

MANY vigorous protests have been raised by voices more influential than ours against the scheme, dear to quacks, of gaining reputations by proxy. Thus the fair reputation of engineering has been appropriated by the "financial engineer" or "human engineer," to say nothing of the bright salesman who has just left ribbons and is now selling radio. Our readers will also know that this journal objects to an indiscriminating use of the word "research" whereby it means anything from a hunt through some 'phone directories made by the office boy during a lazy afternoon to the results of the life work of a scholar.

Having these facts in mind, we entertained certain doubts upon learning a year or more ago that the principal copper producers, rolling mills and brass makers had joined in a "Copper and Brass Research Association" headed by such a well-known scientist as the president of the Calumet & Hecla Mining Co. and advised by no less a consulting engineer on publicity than IVY LEE. A call at their offices confirmed these suspicions. Propaganda, not research, was the object; but "research" is a fine-sounding word. It would lend a certain air to the association's activities.

It excites a feeling almost derisive to find that the association is collecting information by offering fourteen prizes ranging from $150 to $10 to "school children and others for the best photographs showing the relative durability of materials which go into the construction of American homes"—for instance, the old oaken bucket, a knocker, name plate, or grandma's preserve kettle, for it must be at least 35 years old. The scheme recalls the request circulated among the grammar grades of the Salt Lake City schools, asking for suggestions whereby that city could become an inland port for ocean-going vessels! (Yes, that actually happened!)

Since the manager of the association frankly admits that research is not its principal aim, he would be well advised to publish the fact by making the name more descriptive of the activities. Otherwise there is grave danger that the lawyers, financiers and business men who direct the copper and brass industry in the United States may conclude that everything possible is being done to extend and recover the old markets and to find new uses for red metal and its alloys. Meanwhile the Morwell electrification installs 700 miles of high-tension conductors of aluminum at a total saving of $500,000 over copper, France is making subsidiary coinage of aluminum and Russia of paper, and toddle tops are made of wood, celluloid, Bakelite and almost anything but brass.

Incapacity
For Fair Play

NOTHING in the history of organized labor has served to alienate its friends and prejudice its cause so effectively as its acts of violence. Whatever the public sentiment may be, or wherever popular sympathy may lie in any particular labor controversy, there is an instinctive revolt against the side that resorts to violence. Usually labor has been the sufferer.

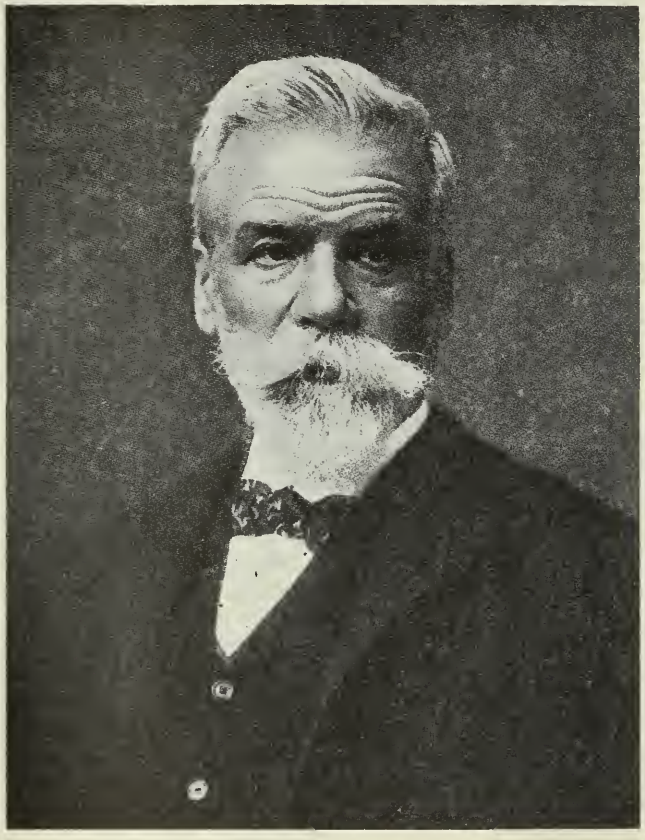
The recent riot and civil warfare that occurred in Illinois is a particularly atrocious example of the intolerance of organized labor which, in the minds of many of its friends, marks its incapacity for fair play. Reports of the fight recall the stories of atrocities that marked the bitterness of the late war. And instead of reprimand or punishment of any kind President LEWIS publicly announced that members of his union were "justified in treating this crowd as an outlaw organization and in viewing its members in the same light as they would view any other common strikebreakers." A noble industrial policy! A high and lofty plan! If a man does not belong to your organization and wants to work when you will not, he is an outlaw and you treat him as you would "any other common strikebreaker." Evidently the approved form is to shoot him down and then proceed with mob violence to destroy property so that nobody can work unless you can get a job on your own terms.

It is beyond all understanding how the presumably intelligent leaders of labor, to say nothing of their followers, expect to gain permanent victories by pursuing this policy. Public decency is only outraged and public opinion reacts against those who commit or condone the crime.

Ernest Solvay, 1838-1922

MAY 26, marks the death, at the age of 84, of a man to whom the chemical industry owes one of its most remarkable developments—Ernest Solvay, the genial creator of the ammonia-soda process. If the introduction of this process, about 60 years ago, marks a memorable milestone in the history of the chemical industry, then there is gleaned from the life of the inventor a moral lesson of the highest order, for it shows us what sustained will power can do when obstinately directed toward the goal it has set for itself.

The early youth of Ernest Solvay was not of the easiest sort. He was born on April 16, 1838, in the little Brabantian village of Rebecq-Rognon, where his father performed simultaneously the duties of master of quarries, salt refiner and wholesale commission agent dealing in oils, soaps and groceries. The diversity of his occupations, however, failed to make him rich and unfortunately he was obliged to renounce the dream he had nourished of permitting his son to take up a complete scientific course in college. He sent him, however, when scarcely 16 years of age, to his uncle Semet, director of the gas works of Schaerbeek, one of the suburbs of Brussels. There the young man was put into a rather crude school, but nevertheless all the more wholesome for his future. There he acquired fundamental knowledge of gas technology; and it was there that he conceived the idea of condensing the residual ammoniacal liquors in order to make their handling more economical and later to recover them by distillation from lime. Finally, studying the compounds of ammonia, he was led one day, in 1860, to his scheme for producing bicarbonate of soda, by observing, it is said, the reaction he provoked by grinding ammonium bicarbonate in a mortar and mixing it with sea water. It is, however, not in this discovery that the great merit of Solvay lies. This reaction, which was later completely to revolutionize an industry, was already known—Dyar and Hemming had discovered it in 1838—and several chemists had even foreseen its industrial application. The glory of Solvay was the research with unexampled tenacity into the causes of the difficulties in the process, and finally to surmount innumerable obstacles and bring his process to a successful industrial status.



ERNEST SOLVAY

On April 15, 1861, he took out his first patent in Belgium; the following year he installed a modest experimental factory near the Place du Marché in Schaerbeek. There, with the help of his brother Alfred, he undertook the elaboration of his discovery. The first experiments resulted in the modest yield of 130 kilos of soda in 12 hours. In 1863 a limited company was established with a capital of 136,000 francs, and a factory was built at Couillet, near Charleroi, but after 5 months the production was still only 227 kilos per day. Thereafter, however, the yield curve rose rapidly; in June, 1866, production had reached 1,500 kilos per day, and double that in December, 1867. In that year, which must always be considered as marking the beginning of the industrial era of the ammonia-soda process, an output of 40,000 tons per year was reached. In 1860 374,000 tons of Leblanc soda was manufactured, and only 300 tons of Solvay soda; in 1902, out of a total production of 1,760,000 tons, the Leblanc process could claim but 150,000 tons.

After the Couillet factory, others sprang up, in France, England, Germany, Russia, Austria and America. Fortune was rewarding the efforts of the inventor, and he was at last able to consecrate himself to occupations of a different character and reveal himself as philanthropist and sociologist of rare conception and accomplishment.

Numerous were the distinctions which consecrated the merit of this eminent man. In 1898 he was made doctor *honoris causa* of the University of Brussels, on which he never ceased to bestow the tokens of his solicitude; the following year the Royal Society of Great Britain elected him an honorary member; on June 18, 1917, he was appointed, almost unanimously, a corresponding member of the chemical department of the Academy of Sciences. He was Grand Officer of the Legion of Honor as well as of the Order of Leopold. Furthermore, he was one of the most illustrious and most representative honorary members of the Société de Chimie Industrielle.

None of those who had the good fortune to come in contact with this octogenarian, who in spite of his age was still so surprisingly alert, will ever forget the impression of meditative and active energy which emanated from him. Ernest Solvay has left us a luminous example of that most intimate co-operation of pure and applied science, but most of all he will forever be remembered, with all the force of this expression, as a truly great citizen. PAUL KESTNER.

EDITOR'S NOTE: We desire to express our appreciation to the Société de Chimie Industrielle, to whose official organ, *Chimie et Industrie*, we are indebted for this photograph of Ernest Solvay and his intimate biography by Dr. Paul Kestner.

Progress in Dust-Explosion Prevention*

The Flour-Milling Industry and Dust Explosions—The Federal Investigation of Dust Explosions—Summary of Dust-Explosion Losses in Various Industries—Progress of Dust Collection and Removal and of Adoption of Methods of Preventing Explosions

By DAVID J. PRICE
Engineer in Charge of Development Work, Bureau of Chemistry, U. S. Department of Agriculture, Washington, D. C.

THE flour-milling industry has given considerable attention to dust-explosion prevention and to the development of effective control methods. The explosion in Minneapolis in 1878 may have been largely instrumental in bringing about this interest and resulting in the progress which has been made by this particular industry. The flour millers have co-operated very effectively with the federal government in conducting special research investigations in connection with this problem, and it has been found that the millers were ready to make quick application of any methods of prevention which proved to be effective.

The principal object in presenting this paper is to develop the fact that the flour-milling industry has made significant progress in controlling dust explosions and reducing the losses from this particular cause. It is desired to suggest that recognition be given to this industry, which has demonstrated very definitely that progress can be made in dust-explosion prevention by the application of dust control measures. If similar progress could be made in other representative industries in which explosive dusts are created during operating processes, it is felt that the large losses of life, grain and property in the United States and Canada would be considerably reduced.

An erroneous impression prevails throughout the United States and Canada to the effect that flour mills are a particular hazard. We desire to take this occasion to correct this impression and state that the fire prevention engineers should no longer take the position that an extreme hazard exists in flour milling, and single out this particular industry in referring to our dust-explosion losses. A natural tendency seems to be to class all mills as flour mills. A thorough study of dust explosions for a number of years has definitely shown that the dust-explosion hazard can be classified as it relates to various industries and in this respect the flour-milling industry has made progress that is worthy of recognition.

Origin of Federal Dust-Explosion Investigation

It is scarcely necessary to state that the investigations now being conducted by the federal government were brought about as a result of the interest manifested by the millers of the country, particularly of western New York, following the disastrous explosion at the Husted Milling Co. plant in Buffalo in 1913. The millers' committee, consisting of L. E. Harmon, then president of the Buffalo Cereal Co., F. F. Henry, manager of the Washburn-Crosby Co., and George P. Urban, of the Urban Milling Co., made it possible for the federal Bureau of Mines to co-operate with the milling industry in a thorough study of the causes of these dust explosions with a view to developing some methods of prevention. The active interest manifested by this committee and the provision made by it for conducting both the necessary engineering and chemical research investigations has been of unmeasured value to American industries.

This work, started by the millers, has resulted in its extension to various types of industries in which disastrous losses have occurred from these dust explosions and fires. It has also led to a thorough investigation of explosions and fires in grain-threshing machines during threshing operations. These explosions occurred about the time the millers made provision for undertaking the work. and the investigations have resulted in the suggestion and adoption of control measures which have been very effective on grain separators, particularly in the Pacific Northwest. It has also extended to the study of fires in cotton gins in the South, in which extensive losses have been experienced. The information obtained in the dust-explosion investigations made possible effective precautionary measures for the control of these cotton-gin fires. In fact the data obtained in the dust-explosion investigations as a whole have found application in the study of various types of explosions.[1] Certain causes have been established that were previously unknown, and methods of prevention applied which had not previously been considered. Reference is made to this extension and development in order to indicate the value of the dust-explosion work.

Recent Dust-Explosion Losses

Although for some time the natural tendency seemed to be to associate dust explosions with dust arising during the handling or milling of grain, investigations have shown that these explosions may occur in any type of representative industry where carbonaceous dusts are created during operating processes. In fact a number of disasters have occurred in recent years in industries in which they had not previously been experienced. In thirteen explosions 154 lives have been lost, more than 200 persons injured and property damaged in excess of $16,250,000.

One of the so-called new kind of explosions occurred in the manufacture of lime sulphur insecticide in powdered form, in which a number of explosions occurred during the handling and collecting of the material. Explosions of aluminum dust, hard rubber dust, wood dust and similar industrial plant dusts have occurred accompanied by loss of life and considerable damage. Some of these explosions have been associated

*Paper read at Millers National Federation Mass Convention, Kansas City, June 1, 1922.

[1]See article, "Engineering Problems in Dust Explosion Prevention," by David J. Price, CHEM. & MET. ENG., vol. 24, No. 1. Jan. 5, 1921.

with our method of handling and collecting dust, which has been quite an important recent development. It appears that certain material can be electrified during the process of collecting and handling and explosions originate in modern dust-collecting systems due to the ignition of the dust by sparks of static electricity. In fact, some recent explosions have indicated that electric sparks in the dust collector have been responsible for the primary dust ignition. This is a significant development, especially in view of the fact that dust was being collected by means of a suction fan instead of a blower fan, the former type of fan being generally considered preferable to the latter when considering the hazard or possibility of dust ignition by a spark within the fan.

Contribution of Minneapolis Explosion to Dust-Explosion Knowledge

The Minneapolis explosion in 1878 made a significant contribution to our knowledge of dust explosions. The experiments of Professors Peck and Peckham of the University of Minnesota in connection with the coroner's inquest have been of very great value to investigators in recent years. In a lecture delivered June 1, 1878, at Association Hall, Minneapolis, Professor Peck demonstrated by a few simple experiments that all combustible material, when finely divided, forming a dust or powder would, under proper conditions, burn with explosive rapidity.

It is well recognized that the explosion resulted in the elimination of the old stive or dust room and led to the introduction of improved types of dust-collecting systems. The improvement in the method of dust collection in the flour-milling industry has been very marked indeed, with the result that today the average modern flour mill is maintained up to a high standard. This explains to a great degree the localizing or minor effect of these explosions when they do occur in flour mills. It is significant to note that the damage is much smaller than explosions from comparative causes in other branches of industry. The efficiency of the dust-collecting systems has made it possible to keep the mill clean and prevent the dust from collecting in dangerous quantities throughout different parts of the plant.

Comparison of Dust-Explosion Losses

Flour Mills

Although the explosion in the Washburn-Crosby Mills, Minneapolis, on May 2, 1878, is referred to as the first dust explosion in this country, the records show that from 1860 to 1878 there were at least seven explosions in flour mills, principally of a minor nature, however. Five of these explosions were caused by the use of open-flame lanterns. The Minneapolis explosion resulted in the loss of eighteen lives and property damage to the extent of $800,000, with the destruction of five separate mill buildings.

From 1878 to the present time records have been obtained of twenty-seven explosions in flour mills. Of this number the explosions at Cleveland, Ohio, in 1888, at Litchfield, Ill., in 1893, and at Portland, Ore., in 1909, stand out as the most prominent. These explosions since 1878 have been of limited proportions and have not caused as extensive damage as has occurred in other lines of industry. It is a safe statement, therefore, that the flour-milling industry has made more progress in dust-explosion control than any other representative industry, and considering the large number of flour mills and the small number of explosions and the limited proportions, it must be recognized that this industry has made progress in connection with this problem. The explosion on March 15 in one of the modern flour mills in Kansas City has been thoroughly investigated by the Bureau of Chemistry and has confirmed the conclusion that when dust explosions occur in this industry both the extent of the explosion and the damage done are limited. It is the feeling of the engineers of the Bureau of Chemistry that the flour mills of the country are maintained on a very high standard and that the operating millers fully understand the problems of dust-explosion control and therefore adopt the necessary precautionary measures.

From 1860 to the present time the Department of Agriculture has record of thirty-five explosions in flour mills, and although figures are not available for the loss in all of these explosions, in thirteen cases it has amounted to $2,537,000, an average of approximately $181,000. The largest damage was in Minneapolis in 1878, amounting to $800,000, with eighteen lives lost. It is significant to note that since 1878 there has not been a flour-mill explosion resulting in such extensive loss of life and property. The records indicate that only four lives have been lost and nine persons injured in flour-mill explosions since 1878. It is therefore well recognized that the necessary steps for dust-explosion control do not apply as much to flour milling as to some of the other grain-handling plants. The high standard in which flour mills are maintained, together with the efficient mechanical equipment, has made it possible for the industry to control the extent of these dust explosions and the resulting damage. The field of service in dust-explosion prevention lies among the other types of grain-handling plants and their methods of operation. It is hoped that the flour-milling industry will continue to maintain this control, and that the insurance companies will recognize the progress made.

Grain Elevators

It is desired to contrast the increase in dust-explosion losses in other industries with the reduction in losses in the flour-milling industry. In considering grain elevators, we find that the first explosion of any importance reported to the department occurred in Toledo in 1898, 20 years after the Minneapolis explosion, with the loss of ten lives and injuries to five others. In Richford, Vt., 1908, ten years later, an explosion in an elevator caused the loss of seventeen lives and injuries to three others. Two women on the railroad track adjoining the plant were killed as a result of the explosion.

There have been thirty-six explosions reported as occurring in grain elevators since 1898. It is observed that up to 1916 the losses from explosions in grain elevators had been minor. During that year an explosion in an elevator in Peoria, Ill., caused a loss of $600,000 and in the same year an explosion in an elevator at Baltimore caused the death of seven workmen, injuries to twenty-two others, and $1,500,000 property damage.

In 1917 a large elevator in Brooklyn, N. Y., was destroyed by an explosion, with losses reaching to $1,750,000 and the destruction of sufficient grain to feed 200,000 persons for an entire year. In 1919 the Canadian Government elevator at Port Colborne, Ont., was wrecked by a dust explosion causing the loss of ten lives, injuries to ten others and $1,500,000 property damage. A month later, in September, 1919, an explosion in an elevator in Kansas City killed fourteen work-

men and injured ten others and destroyed property to the extent of $500,000.

The most disastrous grain-elevator explosion on record occurred in the North Western Elevator operated by the Armour Grain Co., at South Chicago, Ill., March 19, 1921. All the workmen in the elevator at the time (six in number) were killed. The total damage approximated $4,000,000. This amount was equally divided between grain loss and property damage.

In twenty-six explosions in grain elevators in which figures are available, the damage has amounted to $11,722,555, an average of $450,000 for every explosion. In seven of these explosions there have been sixty-seven lives lost and seventy-two persons injured.

The field of work in this problem lies in the development of preventive methods for dust-explosion control in grain elevators. The large scale of operation, the size of our plants, the large quantity of dust produced during the handling, elevating and storage of grain and the introduction of new ignition sources make necessary thorough investigations of this particular phase of dust-explosion control.

Cereal and Feed Mills

One of the first explosions of any size reported as occurring in cereal and feed mills took place in Cedar Rapids, Iowa, in 1902. This was followed in 1905 by a similar explosion in the same plant causing $1,000,000 property damage. In 1910 a Buffalo feed-grinding plant was wrecked by an explosion in which five lives were lost and seven workmen were injured. In 1913, which is really the epoch year in dust-explosion investigations (the year in which the present study began), an explosion in a feed-grinding plant in Buffalo resulted in the death of thirty-three workmen, injuries to eighty, and $465,000 property damage. Probably one of the most damaging explosions in a feed-grinding plant occurred in Petersborough, Canada, in 1916, in which seventeen lives were lost, sixteen persons were injured and $2,000,000 worth of property was destroyed.

The Department of Agriculture has obtained records of twenty-nine explosions in cereal and feed mills. In twenty-two of these explosions the loss has been $4,959,600, an average of $225,436. In seven of these explosions sixty lives have been lost and in ten explosions 128 persons were injured.

Starch and Corn Products

In 1908, in Providence, R. I., a starch-dust explosion caused the loss of seven lives. In 1912 an explosion in a starch factory in Illinois resulted in the loss of fourteen lives and injuries to nineteen others. The most destructive dust explosion on record in this country occurred in Cedar Rapids, Iowa, in a starch factory in 1919. Forty-three lives were lost, thirty persons were injured and more than $3,000,000 worth of property was damaged.

In seven of these starch-dust explosions, seventy-two lives were lost and eighty-nine persons were injured. The total money loss in ten has been about $3,811,000.

Miscellaneous Explosions

In 1917 an explosion of pulverized sugar dust in New York caused the loss of twelve lives and twenty-four injuries and more than $1,000,000 property damage. There are ten sugar dust explosions on record.

Violent explosions of chocolate and cocoa dust have also occurred. In one instance an explosion in a New England chocolate plant caused the loss of three lives and $750,000 property damage. Among miscellaneous explosions may be included explosions in rice mills, fertilizer plants, paper works, wood-working establishments and tanneries. In 1899 in Rhode Island an explosion of soapine dust resulted in the loss of two lives and injuries to nine persons. The department has investigated explosions of cork dust, spice dust, sulphur dust, powdered milk dust and many others. In 1920 an explosion of aluminum dust in connection with the manufacture of aluminum goods in a Wisconsin plant caused the death of six girls and injuries to six others. A few months later an explosion of hard rubber dust in Michigan caused the death of eight workmen and considerable property damage.

European Explosions

Records have been obtained of twenty-four dust explosions in European countries. In eleven of these explosions ninety-one lives have been lost and more than 200 people injured. In an explosion in a meal mill in Liverpool in 1911, thirty-nine persons were killed and 101 injured. In 1908 in a sugar dust explosion in Paris, three workmen were killed and forty-nine injured.

Totals

A total of 242 dust explosions in industrial plants in the United States and foreign countries has been reported to the department. In fifty-two of these explosions, 379 lives have been lost and in sixty-nine of them 651 persons have been injured. The total money loss in 110 explosions in which figures are available has been approximately $30,000,000, an average of more than $270,000 for each explosion.

This does not include the losses in connection with the thresher explosions or cotton gin fires, and is confined entirely to the losses occurring from these dust explosions in industrial plants. In the Pacific Northwest thresher explosions and fires have resulted in approximately $1,000,000 damage and the losses from cotton gin fires in the South have also been very great.

The results of the investigations of the Department of Agriculture from the time the work was initiated by the millers are about to be published in book form by the National Fire Protection Association.

Grain Elevators and the Dust Problem

Dust-explosion control has been brought about in representative industries by effective dust collection and removal. This has been possible in industries where the dust means commercial product with a market value. However, the matter as it relates to grain elevators in the United States and Canada needs special attention. We stand in the same position today in which we always have stood, so far as the dust-explosion problem relates to this type of grain-handling plant.

We cannot expect to control these explosions in grain elevators until some advancement similar to that made in flour milling, in so far as dust collecting is concerned, can be brought about. Mechanical methods of dust collection consisting of the necessary fans and piping systems are essential for dust control. It has been found on grain-threshing machines that dust-collecting fans remove the explosive smut dust and reduce the explosion hazard. The principle has been applied successfully on a commercial scale and now awaits application in grain elevators.

At the present time, existing commercial regulations

prohibit the installation of equipment of this kind in the grain elevators of the United States and Canada. These regulations are not based in any way on the explosion phase of the problem, but have to do with possible abuses leading to difficulty in checking weights, thereby affecting the shipper.

It appears that difficulty has always been experienced in maintaining the weights between shipper and receiver on grain entering the terminal markets. This has led, in some instances, to special provision whereby the grain elevator operator is prohibited from taking any steps which might in any way interfere with the weight of grain going into the plant.

Although these regulations were put into effect before science had determined that the dust was highly explosive, the application affects the proposition just the same. It is well recognized by the dust-explosion prevention engineers and the grain industry as a whole that it will be necessary for the dust to be removed effectively by mechanical systems before we can make the necessary progress. At the present time the dust escapes from the grain-handling equipment and settles on ledges, beams and girders throughout the plant. When the original ignition of dust occurs, there is sufficient concussion to shake this dust loose and propagate flame, resulting in a secondary explosion of large proportions. If the dust is effectively removed, of course the explosion is localized and the damage minor in extent, such as has been referred to in the explosions that have been occurring in flour mills.

Dust Removal in Grain Elevators

This phase of the problem is possibly the most important one that the department is now called upon to study. The Canadian Government has appointed a representative committee, in co-operation with the Dominion Fire Protection Association, to co-operate with similar agencies in the United States to determine the practical possibilities of dust removal in grain-handling plants. The National Board of Fire Underwriters, in conjunction with the National Fire Protection Association, the National Safety Council and other representative agencies in this country, has recently appointed a similar committee for co-operation with the Canadian officials. The object and purpose of the committee will have to do with finding some uniform method of removing and controlling the dust in the grain elevators of both countries.

The Industrial Commission of Wisconsin has recognized the importance and necessity of this provision. Some months ago steps were taken to require the installation of exhaust systems in the grain elevators in the State of Wisconsin, particularly at points such as Milwaukee, Manitowoc and Superior. The request of the commission not being complied with, a conference was called in Madison, March 21, at which the operators were called upon to give the reason why the order of the commission had not been obeyed. It developed that although the grain operators were in hearty sympathy with the object and purposes of the commission and felt that this provision should be made, it would probably discriminate against Milwaukee as a terminal market. This was especially true if points such as Chicago, Minneapolis and other large grain-handling markets were not required to make similar provision. A general conference of all grain-handling states was suggested and is now in the course of consideration. The Department of Agriculture has been called upon to co-operate and has already advised the commission that the department is in hearty sympathy with the plan and will give all possible help and assistance.

Adoption of Preventive Measures

Is it going to require a series of disastrous dust explosions causing larger loss of life and extensive property damage before the importance of adopting effective preventive measures in grain elevators is fully appreciated? It has already been stated that 154 lives have been lost in recent dust explosions in industrial plants, with a large number injured and considerable property and foodstuffs destroyed. It appears, however, that it is only too true that we too often measure progress in safety by catastrophe. There is a difference in work of this nature between killing 154 people in thirteen explosions occurring in different parts of the United States and killing that number in one explosion. Unfortunately as a rule the interest in the subject is measured locally by the extent of life loss and damage by the explosion. Will it require a catastrophe such as the Iroquois Theater fire in Chicago or the Knickerbocker Theater disaster in Washington to concentrate attention on the importance of readjusting our commercial practices in so far as grain elevators are concerned?

We must regard the dust as explosive material such as dynamite, powder or gasoline and take the necessary steps for protection of life, foodstuffs and property. Are we ready for these steps, or must we wait for more explosions, accompanied by extensive loss of life?

Co-operation by Flour-Milling Industry

We have endeavored in this brief paper to call attention to the very effective steps which have been taken by the flour-milling industry to control the dust-explosion hazard. We have also attempted to outline a future program in which it is hoped that the dust-explosion prevention work can be brought to the attention of the operators of grain elevators and other types of dusty industries in such a way that they may profit by the experience of the flour millers and reduce their explosion losses by adopting efficient methods of dust collection and removal.

The flour millers of the United States and Canada are in a position to render valuable assistance in this work and their co-operation is earnestly requested. Many mills are operated in connection with grain elevators or vice versa, and here the operators have an opportunity to see that the same precautions for the protection of life and property which have proved effective in the mill are adopted in the elevator. In business association an opportunity is also frequently offered for the careful operator to call to the attention of the negligent ones the saving which can be effected in both life and property by the adoption of effective dust-collecting and removal methods, and in this way render valuable assistance both to the industry and the country. The Department of Agriculture asks for a continuation of co-operation with the flour-milling industry in the efforts now being put forth to develop methods of prevention that will prove effective in reducing our dust-explosion losses. The interest in explosion control manifested by the industries has assisted in the adoption of effective precautionary measures developed by engineers in the Bureau of Chemistry. The results of recent investigations can be obtained upon request.

Strength and Elasticity of Boiler Plate at Elevated Temperatures

Proportional Limit Maintained or Increased With First Temperature Rise — Tensile Strength Has a Slight Maximum at About 250 Deg. C., but Both Fall Off Badly at Higher Temperatures— Reduction and Elongation Have a Minimum at About 260 Deg. C., but Recover Their Original Value Around 450 Deg. C.

By H. J. FRENCH
Physicist, Bureau of Standards

Previous Investigations

IT HAS long been known that temperature above the ordinary atmosphere is accompanied by changes in steels, particularly in strength and ductility. A large number of interesting and important papers dealing with various phases of this subject have appeared from time to time, but our knowledge is still unsatisfactory and a better understanding of these changes will undoubtedly be of benefit to industry. Howe[1] long ago called attention to the apparent anomalies found in the effects of work at moderate temperatures upon the properties of wrought iron and steel used in boiler construction. Certainly from the standpoint of engineering design it is important to know how the proportional limit varies with changes in temperature, but unfortunately this is the most difficult to determine, and available data are conflicting.

In Fig. 1 is given a summary of results obtained in some of the more important published investigations of the tensile properties of wrought iron at high temperatures. Increase in strength with first rise in temperature above that of the room is reported by Huntington,[2] Epps and Jones,[3] while J. E. Howard[4] finds a slight decrease between about 50 and 150 deg. C. (125 and 300 deg. F.), which is followed by increase to a maximum between 205 and 345 deg. C. (400 and 600 deg. F.). In a very complete series of tests of steels of varying carbon contents Howard further found that the minimum tensile strength occurring with first rise in temperature was generally more quickly reached the lower the carbon content and that the higher carbon steels attained their maximum strength at lower temperatures than medium- or low-carbon alloys.

Elastic Properties

Various investigators have from time to time reported decrease in elastic properties with increase in temperature. Epps and Jones obtained first a decrease then an increase at a slightly higher temperature, with maximum at about 180 deg. C.

In his tests Howard found that the interval between the elastic limit and the maximum stress showed particularly interesting features. Several of the different steels tested showed a yield point at the elastic limit, this period being marked by rapid stretching, which, once begun, continued under reduced loads. Such yielding rarely occurs in testing steel at room temperature, but was observed by Howard up to about 260 deg. C. (500 deg. F.) in tests of mild steels and at temperatures somewhat below this in the higher carbon alloys. Bars tested between about 95 and 205 deg. C. (200 and 400 deg. F.) showed alternate periods of relaxation and rigidity under increasing stress resembling a succession of yield points apparently indicating some remarkable changes taking place within the metal in this temperature range.

There is more general agreement in various publications regarding changes in ductility as measured by elongation and reduction of area. Elongation decreases

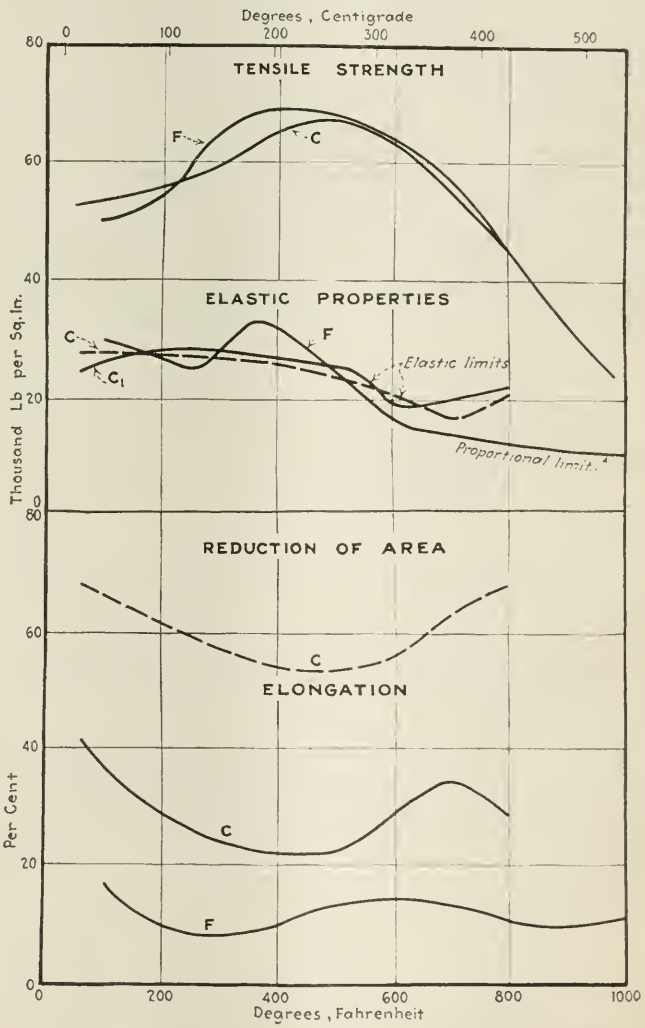


FIG. 1—TENSILE PROPERTIES OF WROUGHT IRON AND STEEL AT VARIOUS TEMPERATURES

slowly just above room temperature and thereafter more rapidly to a minimum variously reported as occurring between 125 and about 200 deg. C. (255 and 390 deg. F.). It then increases rapidly. Reduction of area likewise decreases but little just above the temperature of the room, but then drops rapidly to a minimum reported to occur between 200 and 300 deg. C. (390 and 570 deg. F.) and is followed by rapid increase in values. Howard also found a tendency for bars broken at temperatures between 205 and 315 deg. C. (400 and 600 deg. F.) to fracture in an oblique shearing direction.

Steels Tested

The steels tested in this investigation were received as half-inch boiler plates of firebox and marine grades. The specified tensile strength and composition for each are shown in Table I, but the third class listed showed

TABLE I—STEELS TESTED

Series	Grade	Specified Tensile Strength Lb. Per Sq. In.	Composition, Per Cent C	Mn	P	S

slightly higher tensile values than the limits prescribed and was supplemented by class 4. The former was, however, used and the tensile properties at high temperatures of the hot-rolled steel were determined, because the number of plates of the first two series was insufficient for completion of the desired tests.

The steels were made in the basic open hearth and the baths kept in a boiling condition up to the moment of casting. Such metal is often referred to as "open steel." It is porous in its cast condition and shows some segregation, but is nearly free from pipe. Variations in composition have, however, been kept to a minimum by cutting the patterns from which the test specimens were machined from steel originally in the central and least segregated portion of the ingot.

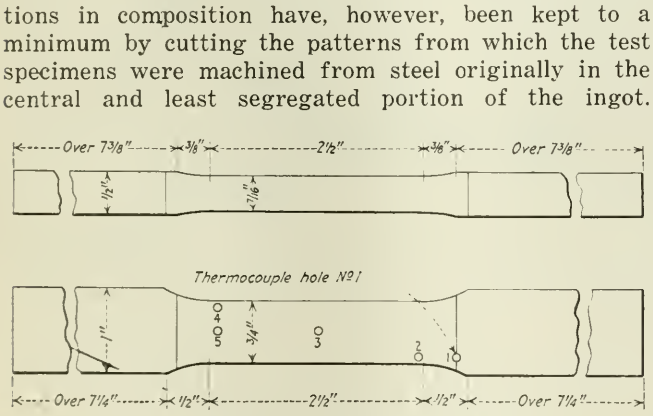

FIG. 2—FORM OF TEST-BAR USED

Small circles numbered 2, 3, 4 and 5 represent thermocouple holes drilled in one sample only, to explore uniformity of temperature distribution.

Check analyses made from time to time during the progress of these tests show excellent uniformity and agree closely with the compositions shown in Table I.

Flat test-bars, with long dimension in the direction of rolling, were cut from patterns taken from these plates and machined to the form shown in Fig. 2.

Apparatus for Determination of Proportional Limit

At the outset emphasis is laid on the fact that, for the work required throughout the various sections of this investigation, suitable and readily manipulated apparatus and not the most accurate mechanism available was sought. The material under test is lacking in entire uniformity, so it appeared undesirable to erect elaborate equipment requiring a great deal more time in development and actual test.

The apparatus used in determination of the limit of proportionality at various temperatures is substantially as described by the writer in CHEMICAL & METALLURGICAL ENGINEERING, Jan. 19, 1921, vol. 24, p. 131, "Motion Pictures in Physical Testing Laboratory."

The smallest division on the instruments used was equal to 0.001 in., but estimated readings to the nearest 0.0001 in. were readily obtained.

Heating Furnace

The test specimens were heated by means of an electric tube furnace 11 in. long. For heating elements two spiral resistors in series were used. One covered the entire outer surface of the tube and the other was concentrated at the ends, the two requiring about 80 ft. of 22-gage nichrome wire. Yokes and major part of the 18-in. test-bar and rods were contained in the heating chamber. A comparatively small temperature gradient was obtained under suitable operating conditions, as the effective heating length during a determination was about 3 in. and located at the center of the tube length.

Test Procedure

The method of setting up the apparatus, together with procedure followed in actually carrying out the tests, was substantially as follows: A specimen was marked on one surface with a double-pointed center punch leaving marks 2 in. apart. Next yokes were attached to the specimen, fixing a setscrew into these impressions. Then, by lightly tapping the opposite side of the yoke, containing two screws, an impression of their exact location on the test-bar was obtained. These points were then enlarged by the use of the double-pointed center punch and the yokes carrying rods and frames were firmly attached to the test-piece.

The specimen was then passed up through the furnace until the rods appeared above the top, when the upper frame spanning the furnace was lowered into position and fastened to the rods. After the furnace was placed on a stand and the specimen was in the jaws of the testing machine, the dials were attached to the frame and adjusted to zero. The completely assembled apparatus is shown in the article in these columns referred to just above.

When thermal equilibrium at the desired temperature was reached, an initial load of about 1,500 lb. per sq.in. was applied, and the dials read or, as a matter of convenience, again set at zero. Readings were then taken at increments of 500 or 1,000 lb. actual load until the proportional limit was passed. The dials were then removed and the specimen was broken in the usual

TABLE II—TEMPERATURE SURVEY

165	165	173	167	158	165	15	166	15
320	310	327	327	310	322	0	322	17
	325	334	334	320	329	5	329	14
	325	336	334	318	332	20	330	16
400	402	415	412	393	402	10	405	22
	402	415	412	393	402	20	405	22

manner with a low rate of extension which approximated the intermittent increases of stress applied during determination of the limit of proportionality. Tests at each temperature were made in duplicate or triplicate and the proportional limit was obtained from a stress-strain diagram. Temperature was measured by a 22-gage standardized chromel-alumel couple connected to a Leeds & Northrup portable potentiometer. The end of the couple was inserted directly into a small hole drilled in the specimen at the fillet.

Thermal Equilibrium

In order to obtain reliable and satisfactory results with the method described in the preceding paragraphs, thermal equilibrium must be reached prior to the start of the loading and maintained during the actual 8 to 15 minutes during which the test is being carried out. An adjustable resistance in series is used to balance the loss of heat from the furnace and specimen. The effect of temperature variations may be large unless care is taken to allow sufficient time for the specimen to become uniformly heated throughout after the potentiometer has once indicated the desired temperature. The dial readings will assist in determining when equilibrium has been reached and is being maintained.

Temperature determinations under actual test conditions made by placing thermocouple in holes located at various points in a specimen carrying entire auxiliary apparatus show that the position chosen for the single thermocouple (in the fillet) is representative of about the mean of the gradient throughout the gage length, where the temperature gradually decreased from top to bottom (see Table II for partial reproduction of these variations). This variation is within 30 deg. C. (54 deg. F.) during the upper temperature ranges under consideration and does not exceed 20 deg. C. (36 deg. F.) at the lower temperatures used. However, as the thermocouple, specimen with auxiliary apparatus and furnace are in the same relative position in each test, the results obtained at various temperatures throughout the range 20 to 465 deg. C. (70 to 870 deg. F.) are comparable.

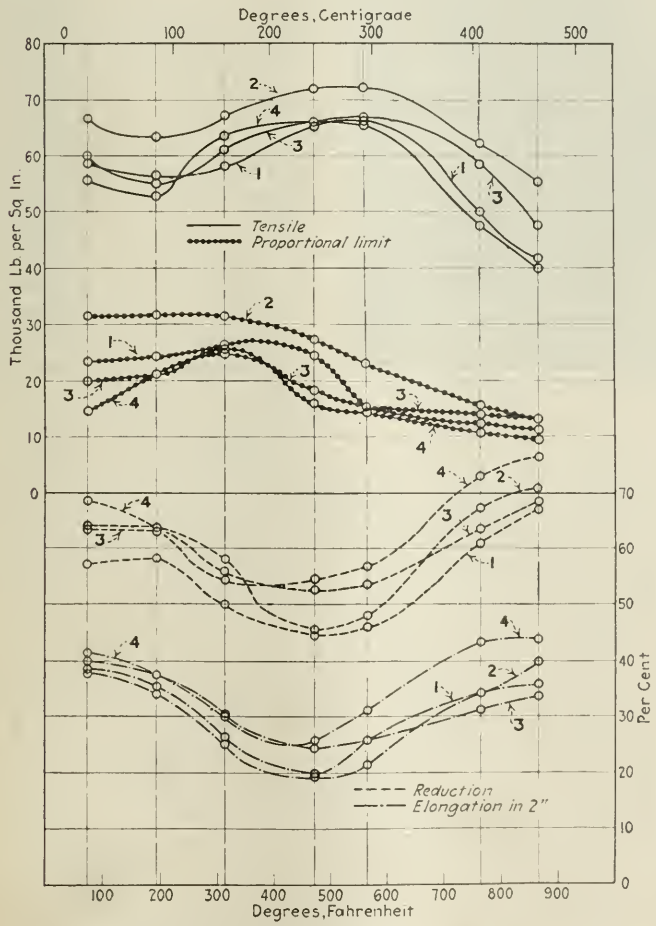

FIG. 3—TENSILE PROPERTIES OF FOUR GRADES OF BOILER PLATE MADE OF OPEN-HEARTH STEEL

Tensile Properties of Hot-Rolled Boiler Plate at Elevated Temperatures

Tensile tests were made on the four grades listed in Table I. Results obtained are graphically represented in Fig. 3.

In all grades of plates increase in temperature above the ordinary atmospheric range is accompanied by distinct changes in strength and ductility, viz.:

(a) Tensile strength decreases a few thousand pounds per square inch in the neighborhood of 95 deg. C. (200 deg. F.). This is followed by a maximum which occurs at 290 deg. C. (550 deg. F.) in plates of the first three series and at about 250 deg. C. (480 deg. F.) in series 4, representing plates of lowest tensile strength. With further increase in temperature the strength decreases and again approximates ordinary atmospheric temperature values in the range 370 to 400 deg. C. (700 to 750 deg. F.).

(b) The limit of proportionality increases to a maximum in the neighborhood of 150 deg. C. (300 deg. F.). Firebox-grade increases more markedly and it is maintained to a higher temperature than marine plate. The latter has in effect constant proportional limit up to about 175 deg. C. (350 deg. F.). While such differences are noticeable at these relatively low temperatures, the proportional limit of the higher tensile strength marine plate is practically the same at 365 deg. C. (870 deg. F.) as that of series 1 and 3 firebox-grade plates and but slightly higher than that of the fourth series (railway firebox plate of lowest tensile strength).

(*c*) Only a slight decrease in elongation is observed until a temperature of about 95 deg. C. (200 deg. F.) is reached, above which the rate of decrease is much higher and a minimum is reached at about 245 deg. C. (470 deg. F.). Elongation then increases, but does not, throughout the range under consideration, reach the ordinary atmospheric temperature value in the marine plate (rated at 60,000 to 70,000 lb. tensile strength) and but slightly exceeds its room temperature value in the fourth series at 465 deg. C. (870 deg. F.).

(*d*) Reduction of area closely follows the inflections registered in the curves for elongation, but reaches a minimum at a slightly higher temperature except for the lowest tensile strength firebox plate, where the minimum occurs at practically the same temperature as that for elongation. At 465 deg. C. (870 deg. F.) reduction of area is greater than the value obtained at atmospheric temperature in each of the four series of plates tested.

It is to be noted that maximum tensile strength does not coincide with minimum reduction of area or maximum proportional limit, but examination of Fig. 3 indicates that the inflections in the curves for reduction of area are in general more nearly coincident with the reverse inflections in the curves for tensile strength and that elongation and proportional limit may be similarly paired.

C. R. DeLong, Chief, Chemical Division, Department of Commerce

MORE than usual significance attaches to Secretary Hoover's recent announcement that a commodity division devoted exclusively to chemicals and related products is to be established within the organization of the Bureau of Foreign and Domestic Commerce. Ever since the bureau was reorganized on a commodity basis there has been an evident need for this recognition of the chemical and allied industries. The actual organizing of the chemical division has been delayed, however, due both to the lack of available funds and to an apparent unwillingness on the part of a small minority of the chemical industry to join with Secretary Hoover in his efforts to make the Department of Commerce an active, vital aid to industry.

Photo by Clinedinst, Washington.

C. R. DeLONG, CHIEF, CHEMICAL DIVISION

Selecting a man to head this important division has not been an easy task for the department, but the recent news that the position has been offered to C. R. DeLong, chief of the chemical staff of the United States Tariff Commission, would appear to meet with the unanimous approval of the chemical industry. For a number of years Mr. DeLong has been very closely identified with, and in many cases largely responsible for, the Tariff Commission's excellent investigations and reports on the chemical industries. This work has given him an unusually broad knowledge of conditions in the domestic industry, particularly as it has been affected by the competition of the foreign manufacturers of chemicals. Experience of this sort cannot help but be of greatest assistance to him in analyzing the needs of the chemical industry and wisely interpreting them to the Bureau of Foreign and Domestic Commerce.

Carl Ray DeLong, who on Aug. 1 will assume his new duties as Chief of the Chemical Division, was born and educated in Ohio. He was graduated from the Ohio State University, Columbus, Ohio, in 1914, receiving the degree of Bachelor of Science in Chemical Engineering. After finishing his college training he was employed for a year and a half by the Ohio State Geological Survey and under the direction of Prof. James R. Withrow he completed a comprehensive survey of the industrial water supplies of Ohio. This work was followed by industrial experience in Kingsport, Tenn., in the manufacture of electrochemical products and dye intermediates. In 1917 this manufacturing experience led to a position with the Electron Chemical Co., of Portland, Me., where Mr. DeLong was engaged in research work on the commercial production of acetic anhydride and certain related organic compounds. In January, 1918, when the U. S. Tariff Commission began its more intensive investigations in the chemical industry, Mr. DeLong was selected to carry on a responsible share of that work. His first duties were largely in connection with the so-called tariff information surveys, especially those dealing with heavy chemicals and electrochemical products. His report on "Barytes, Lithopone and the Barium-Chemical Industry" is an outstanding example of thorough investigation and the accumulation of data of value not only to the government but to the industry itself. Following the resignation of Dr. Grinnell Jones in 1920, Mr. DeLong was put in direct charge of all the investigational work of the chemical division of the commission. Under his direction a great many valuable reports of economic conditions within the different chemical industries have been prepared and published. Most widely known among these, perhaps, are the four editions of the *Census of Dyes and Coal-Tar Chemicals* (1917-1920), the *Tariff Information Surveys* on Schedule A (19 pamphlets) and on chemical products of the Free List (12 pamphlets), and the two editions of the *Summary of Tariff Information* prepared respectively for the Ways and Means Committee and the Senate Finance Committee.

During the actual framing of the permanent tariff bill and the various legislative measures designed for the protection of the domestic dye industry, Mr. DeLong was in active and intimate contact with the Congressional committees in charge. The value placed on his services in that connection was recognized not long ago by Congressman Nicholas Longworth who, in explaining to Congress the vast amount of technical work involved in the preparation of the chemical schedule of the tariff bill, made public acknowledgement of the invaluable assistance which Mr. DeLong had given to the Ways and Means Committee.

Thus it may readily be seen that Mr. DeLong is unusually well qualified to carry on the important work of the new division. Many of the contacts already made with individuals and associations within the chemical industries will prove of inestimable value to him. A number of important industrial groups have already offered their whole-hearted co-operation—and it is confidently expected that the entire chemical industry will stand squarely behind the new division and give it the support that will make it a factor in speeding the return of prosperity to American business.

S. D. KIRKPATRICK.

Recovery of Glycerine From Spent Soap Lyes

Composition of Spent Soap Lyes—Removal of Impurities by Single and Double Treatments—Concentration of Purified Lyes in Single-Effect Evaporator Unit—Practical Data on the Equipment Required and Methods of Operating It to Obtain Maximum Efficiency

By WALTER E. SANGER
Chemical Engineer, Chicago, Ill.

ALL true animal and vegetable fats and oils are combinations of glycerine and various organic acids. The most common of these compounds are stearin, olein and palmitin, which are combinations of glycerine with stearic acid, oleic acid and palmitic acid respectively.

Glycerine is obtained upon the saponification of a triglyceride, the chemical reaction being as follows:

$$(R.COO)_3C_3H_5 + 3MOH = C_3H_5(OH)_3 + 3R.COOM$$

In this equation, *M* stands for hydrogen or a monovalent metal and *R* represents the alkyl radical of any fatty acid.

In soap-kettle practice, the fat or oil is usually saponified with caustic soda. Taking, then, the saponification of the glyceride tristearin, the reaction is

$$\underset{\text{Tristearin}}{(C_{17}H_{35}COO)_3C_3H_5} + \underset{\substack{\text{Sodium}\\\text{hydroxide}}}{3NaOH} = \underset{\text{Glycerine}}{C_3H_5(OH)_3} + \underset{\substack{\text{Sodium stearate}\\\text{(soap)}}}{3C_{17}H_{35}COONa}$$

and it is thus seen that upon the saponification of a tri-glyceride with caustic soda there is produced glycerine and a sodium soap. Sodium soap is soluble in water, but is practically insoluble in brine.

After the glyceride is thoroughly saponified, sodium chloride is added to the charge in the kettle in order to separate the soap. The charge then separates into three layers—soap (which floats on the top of the charge), nigre (which remains suspended just below the soap and which is made up of soap, water and impurities) and spent soap lye (which settles to the bottom of the kettle and which contains most of the glycerine).

Composition of Spent Soap Lyes

Spent soap lyes as they are drawn from the soap kettle consist, in general, of glycerine, salt, caustic soda, sodium carbonate, soap, fatty acids and water in addition to albuminous and oleaginous matter. The proportions of these ingredients vary considerably with kettle practice and also with the various stocks saponified. The most valuable ingredient is glycerine, the percentage of which will vary with the stock used and the amount of lye drawn from the kettle.

The first lye drawn from the kettle will contain the highest percentage of glycerine, while as many as thirty succeeding draw-offs will show glycerine on analysis. The amount of lye to be drawn from a kettle will depend on the price of glycerine. If lyes are removed with too low a glycerine content, the cost of recovery will exceed the value of the glycerine obtained.

The following results were obtained by the writer in a test saponifying about 30,000 lb. of tallow, containing 85.3 per cent of neutral fat:

	Weight, Lb.	Glycerol, Per Cent
1. Killing change	12,742	8.47
2. Rosin change	7,202	4.65
3. First wash	5,263	3.76
4. Second wash	3,787	3.30
5. Third wash	8,033	2.80
6. Fourth wash	7,202	2.36
7. Fifth wash	7,479	2.10
8. Sixth wash	8,033	1.96

Necessity for Removal of Impurities Before Evaporation

Spent lyes are treated for the purpose of increasing the glycerol content of the crude glycerine obtained on evaporation. The most important impurities to be removed before evaporation are soap and fatty acids, together with the oleaginous and albuminous matter. For this purpose there is usually used a metallic salt such as sulphate of alumina, $Al_2(SO_4)_3$. Soap and some of the fatty acids combine with the salt to form an aluminum soap which is insoluble in water. Some of the salt forms aluminum hydroxide, $Al(OH)_3$, which apparently carries down oleaginous and albuminous matter together with some fatty acids mechanically.

Specifications for Soap Lye Crude Glycerine

The importance of proper treatment is seen on reference to the specifications for soap lye crude glycerine, which are as follows:

> Analysis to be made in accordance with the International Standard Methods (I.S.M., 1911).
>
> *Glycerol.* The standard shall be 80 per cent glycerol. Any crude glycerine tendered which tests 81 per cent glycerol or over shall be paid for at a pro rata increase, calculated as from the standard of 80 per cent. Any crude glycerine which tests under 80 per cent, but is 78 per cent or over, shall be subject to a reduction of one and one-half times the shortage calculated at pro rata price as from 80 per cent. If the test falls below 78 per cent, the buyer shall have the right of rejection.
>
> *Ash.* The standard shall be 10 per cent. In the event of the percentage of ash exceeding 10 per cent, but not exceeding 10.5 per cent, a percentage deduction shall be made for the excess calculated as from 10 per cent at contract price, and if the percentage of ash exceeds 10.5 per cent, an additional percentage reduction shall be made equal to double the amount in excess of 10.5 per cent. If the amount of ash exceeds 11 per cent, the buyer shall have the right to reject the parcel.
>
> *Organic Residue.* The standard shall be 3 per cent. A percentage deduction shall be made of three times the amount in excess of the standard of 3 per cent calculated at contract price. The buyer shall have the right to reject any parcel which tests over 3.75 per cent.

An untreated lye, on concentration, will yield a crude glycerine analyzing about 40 per cent glycerol. On reference to the penalties imposed as above outlined, it will be seen that at the present time crude glycerine obtained from an untreated lye has practically no mar-

ket value to the producer when he offers it for sale to glycerine refiners.

As much soap as possible should be removed from the lyes before they go to the lye treatment department. For this purpose there should be available enough storage capacity between the kettles and the lye treatment department so that the lyes may cool sufficiently to separate the soap. The usual practice is to have sufficient storage to hold the spent lye produced during any week.

Lye Purification by Single Treatment

The simplest and probably most common method of lye treatment is that known as the single treatment, which is herewith outlined in detail.

Cooled and settled lyes from which the soap has been skimmed are pumped to a treatment tank which is filled to about 24 in. from the top so as to allow space for agitation. After the proper amount of lye has been run in, preferably a steam blower or ejector is turned on for the double purpose of stirring the lye with air and at the same time heating it. After a few minutes of agitation, a sample is withdrawn before any metallic salt or acid is added.

Metallic salts commonly used are sulphate of alumina and ferric chloride. The former is usually purchased as such, while the latter is usually made by dissolving ferric oxide in muriatic acid.

Either 60 deg. sulphuric acid or 20 deg. muriatic acid may be used. Sulphuric acid is most commonly employed because of its lower cost, although it is objectionable on account of the formation of sulphates which have but little efficiency in separating the soap from water in the kettle. When the sodium chloride which is used for separating the soap from the water, etc., in the kettle contains about 25 per cent of sulphates, the separating or "graining" action is much impaired. If as much as 30 per cent of sulphates is present, it is very difficult to grain the soap.

For simplicity of discussion, we shall assume that sulphate of alumina and 60 deg. sulphuric acid are used.

After a sample has been withdrawn from the treatment tank, from 3 to 5 lb. of sulphate of alumina is added to the tank for each 1,000 lb. of spent lye. The amount to be added is usually determined by experience and will vary with various kettle practices and also with various stocks saponified.

Chemical Control of Treatment

The sample of fresh lye is next filtered and tested. It is most convenient to make the test on 10 c.c. samples, using $N/4$ NaOH and $N/4$ H_2SO_4, since 1 c.c. of standard solution is then equivalent to practically 0.1 per cent of acid or alkali (respectively) in the sample. Phenolphthalein is used as indicator, 1 g. being dissolved in 50 c.c. of alcohol and neutralized with caustic soda to form the stock solution.

We shall assume that the treatment tank is 8 ft. inside diameter and 8 ft. deep inside and that it is filled to a depth of 70 in. with spent lye. A tank of this diameter holds 261.4 lb. of water per inch of depth, so that 70 in. would weigh 18,298 lb. Spent lye is somewhat heavier than water, but calculations are made on water weights to avoid using an excess of materials and so that errors will be made on the correct side.

After adding three or four drops of indicator to a 10-c.c. sample of the filtered fresh lye, $N/4$ acid is run in from a burette until the pink color has been discharged and then an excess of about 4 c.c. is added to neutralize any carbonates or bicarbonates which may be present. Let us assume that the total amount of $N/4$ acid added is 7.2 c.c. After boiling vigorously to expel carbon dioxide, the solution is cooled and the excess acid is titrated with the $N/4$ NaOH until the sample remains pink on standing a short time. Assuming that 2.5 c.c. was required, the difference between 7.2 and 2.5, or 4.7 c.c., is the amount of $N/4$ acid necessary to neutralize the alkali in the sample, or since each c.c. of $N/4$ acid is equivalent to 0.1 per cent of alkali, the original spent lye contained 0.47 per cent of alkali.

In the treatment tank there is 18,298 lb. of spent lye testing 0.47 per cent alkaline or containing 0.47 per cent of NaOH; 18,298 times 0.0047 equals 86.0 lb. of NaOH which must be neutralized.

Assume that the lye under consideration required 3 lb. of sulphate of alumina for each 1,000 lb. of spent lye and that this salt was added *after* the first sample was taken.

Accordingly, 48 lb. of sulphate of alumina was added to the treatment tank after the first sample was taken.

This salt neutralizes about one-third of its weight of NaOH, therefore about 16 lb. of NaOH has been neutralized, leaving 70 lb. still to be neutralized. Since 1.57 lb. of 60 deg. sulphuric acid will neutralize 1 lb. of NaOH, 70 $\times$ 1.57, or 110 lb., of 60 deg. H_2SO_4 is added to the treatment tank and the charge is thoroughly agitated for about 5 minutes.

A second sample is then taken, filtered, and 10 c.c. tested exactly as before. Assume 4.2 cc. $N/4$ H_2SO_4 added and 3.6 c.c. $N/4$ NaOH required to titrate back. The lye is still slightly alkaline—0.06 per cent—and since the original charge of 18,298 lb. has been increased by 95 lb., 18,393 $\times$ 0.0006, or 11 lb., of NaOH still remains to be neutralized, requiring 17 lb. of 60 deg. H_2SO_4. This is added, the mixture thoroughly agitated for a few minutes and another sample taken, filtered and tested exactly as before. Assume readings of 4.7 and 4.6 c.c. for acid and alkali respectively. This indicates an alkalinity of 0.01 per cent, which is satisfactory. For normal operating conditions the limits are 0.01 per cent acid to 0.02 per cent alkaline.

Check on Complete Precipitation of Impurities

Spent soap lye treatment is most efficient when all matter which can be precipitated has been separated in this form. As a further check on the treatment, three clear filtered samples are placed in separate test tubes. One sample is neutralized and there is added a drop or two of 10 per cent solution of sulphate of alumina. If sufficient of this salt has been added, the sample will not show a precipitate. If there is a precipitate formed, more salt should be added to the treatment tank. To the second sample there is added a slight excess of ammonium hydroxide and to the third sample a slight excess of dilute sulphuric acid. If the lye has been properly treated, there will be no precipitate formed in either of these two latter samples or else there will be formed the same amount of precipitate in both.

After the above tests have been made and the spent lye is found to be satisfactory, it is pumped through a filter press. Uusally the first filtrate from the press runs cloudy (this is especially true if the lye is cold) and is returned to the treatment tank. After the lye

runs clear it is run to the evaporator feed tank, whence it is fed to the evaporator.

Double Treatment of Spent Soap Lyes

In the double treatment of spent soap lyes, the settled, cooled and skimmed lye is pumped to the treatment tank.

Sulphate of alumina is added to the first treatment tank, the amount being usually determined by experience with the general quality of lye produced. The charge is then stirred violently and warmed, if necessary, by any convenient means. Sulphuric acid (60 deg.) is slowly run into the tank so that the acid is neutralized almost as soon as it enters the tank.

An experienced operator can judge by the appearance of the lye when enough acid has been added. An inexperienced operator can test the charge from time to time by dipping a piece of blue litmus paper in the charge. After there has been added just sufficient acid to turn the blue litmus paper red, the charge is agitated for several minutes to insure thorough mixing and is then finally tested with litmus.

When the lye is in such condition that it just turns blue litmus, it is filtered into a second treatment tank, where caustic soda of any desired strength is added until a sample will just turn red litmus blue. A filtered sample of the lye is tested with a few drops of a 10 per cent solution of sulphate of alumina. If the sample becomes cloudy, more sulphate of alumina is added to the second treatment tank to precipitate everything which can be precipitated by this salt.

When the treatment is satisfactory, the lye is filtered through a press and is ready for evaporation. The caustic treated lye should never be filtered through a press which has in it any filter press cake from an acid filtration, as this would dissolve some of the precipitate obtained in the acid treatment.

The ideal condition of a spent lye for evaporation would be to have it in such condition that there is present sufficient acid to drive off all volatile fatty acids which can be boiled off in the evaporator. The objection to evaporating lyes in this condition is that the corrosion on the evaporator would be excessive. If a spent soap lye is evaporated testing as high as 0.04 per cent acid, the corrosive action of the vapor is quite marked.

Other Methods of Treatment

The treatment of spent lye is by no means limited to the two methods here outlined. There are various other methods of treatment where there are used ferrous sulphate, calcium chloride, milk of lime, sodium carbonate, barium hydroxide, etc., besides treatment at various stages of concentration of the spent soap lye. These treatments are used to meet particular conditions in various factories and do not have a general application.

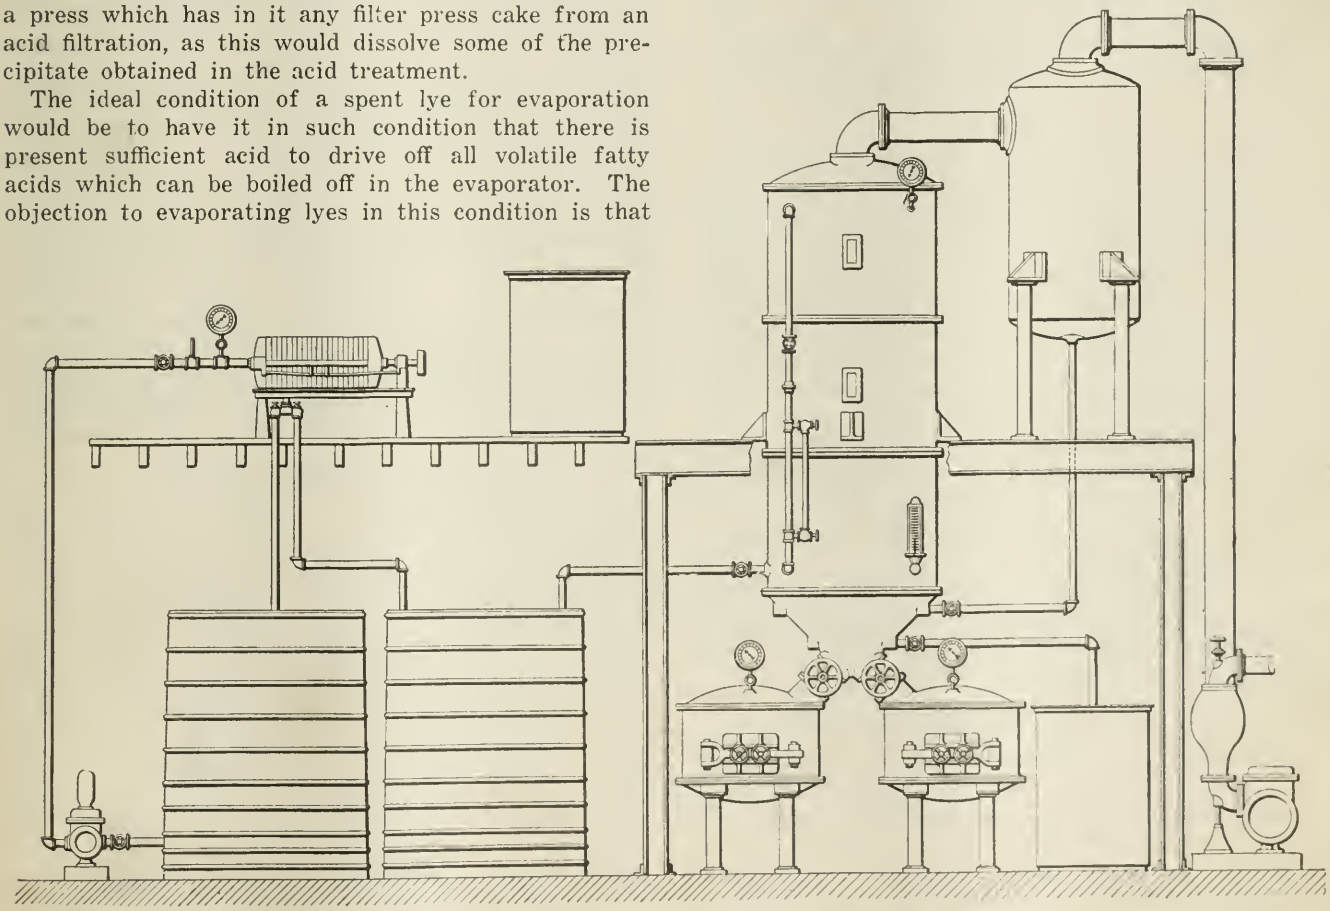
Evaporation of Purified Lyes

The evaporation of spent soap lyes may be carried on in various types of equipment. Probably the simplest type is an open soap kettle equipped with closed coils, but, due to objectionable features, this method of evaporation is practically obsolete.

Evaporation is usually carried on under vacuum in single or double effect. A double-effect evaporator will require about one-half the steam necessary for a single effect of the same capacity and is frequently employed where large volumes of lye are handled. The single-effect evaporator is the type used by most soap works.

For purposes of this discussion we shall assume that evaporation is carried on in a single-effect evaporator, with two salt boxes.

Equipment comprising an evaporator unit consists of the evaporator, salt boxes, catchall, condenser,



EQUIPMENT FOR RECOVERY OF GLYCERINE FROM SPENT SOAP LYES

vacuum pump, vapor lines, liquor lines, instruments and gages.

The evaporator consists of the vapor belt, calandria or steam chest, cover and bottom. It should be equipped with a water-gage column, thermometer and vacuum gage, together with the necessary openings for liquor, steam and vapor pipe connections.

The vapor belt should be equipped with suitable deflector plates to aid in circulation and also to aid in the prevention of glycerine losses through entrainment. It should also have sight glass openings so that boiling of the liquor may be observed.

Calandria

The calandria is usually of the standard vertical tube type. A common arrangement is to have copper tubes expanded into copper tube sheets, the body of the calandria being of cast iron. There has been considerable discussion about an electrolytic action being set up between the copper and the cast iron. The conditions for such an action are present, but the writer is acquainted with evaporators which have been in service for as long as 10 years wherein there is no perceptible deterioration due to such an electrolytic action and which appear to be good for an indefinite number of years of further service. The calandria should be so designed that there is free and positive circulation of the liquor in order that the tubes will not become salted. It should be equipped with baffle plates to aid the circulation of steam and to sweep out any non-condensible gases. It is further equipped with a steam inlet connection and condensation drain.

The cover may be equipped with a faced flange for vapor pipe connection or this connection may be taken from the vapor belt.

The bottom should be of the conical type tapped for liquor lines and with openings for drawing off the salt.

Salt Boxes

Salt boxes are used for the purpose of receiving the salt thrown out of solution upon concentration of the spent lye. They are connected to the bottom of the evaporator by means of salt valves, which are usually of the double wedge gate type. The bottoms of the boxes are connected back into the body of the evaporator above the calandria by means of salt box return lines. These lines should be equipped with valves and fittings so that steam or water may be passed to the salt boxes or to the evaporator.

A catchall is used for decreasing losses by entrainment and also as a separator if a charge is pulled over from the evaporator. It should be equipped with a drain line running to the evaporator and also with a water-gage column.

The condenser may be of the barometric type or else of the jet type directly connected to the vacuum pump. A barometric condenser serves to maintain a more even vacuum than is obtained with the jet type.

Operation of a Single-Effect Unit

In starting the evaporator in operation, the salt valves should be closed, the salt box return lines should be open and all other lines should be closed. The vacuum pump is started and a small amount of water turned on to the condenser. Under these conditions vacuum is pulled on the whole system.

After the vacuum reaches 15 in. or is sufficiently high to pull lye into the evaporator, it is filled to about one-half the height of the calandria. When the vacuum reaches 23 in. or more, a small amount of steam is turned into the calandria. Experience soon teaches just how much steam should be turned on. This should be done slowly enough so that boiling of the lye starts when the vacuum reaches about 25 in. Boiling should start slowly enough so that there is a drop in vacuum not to exceed 2 in. If the vacuum falls more than this, there is great danger of loss of liquor when the vacuum again rises, which it does quite rapidly as soon as the vapors reach the condensing water.

As soon as boiling commences, more water is turned into the condenser so that vacuum may be maintained. When the lye begins to boil, more steam is slowly turned into the calandria and more lye is fed to the evaporator to maintain a level about two-thirds of the height of the calandria. When the lye is boiling well the level in the evaporator is raised and the level of the liquor so maintained that the tubes are continually wet. Steam is increased until there is just a positive pressure on the condensation drain from the calandria. Under such conditions the evaporator is doing its normal work.

Filling the Salt Boxes

After a period depending on the salt content of the lye, salt will begin to crystallize out of the liquor and will drop into the bottom of the evaporator. The presence of salt may be detected in the liquor which is thrown against the sight glasses on the vapor belt. After salt begins to form the lye has no further value in dissolving salt remaining on the tubes from a previous run, as it is then a supersaturated salt solution, the salt valve on one salt box is opened, the steam is turned off of the evaporator momentarily and the charge is dropped into the salt box. The salt valve is left open and the evaporator body is again filled with fresh lye to the former level. While fresh lye is being fed, steam is turned on the calandria, so that the lye is heated to the boiling point as it is fed to the evaporator.

As evaporation continues, the lye again becomes a supersaturated salt solution and salt crystals will fall into the bottom of the evaporator, whence they drop into the salt box. Evaporation is continued and when the salt box is full the salt valve connecting this box to the evaporator is closed and the valve on the salt box return line is opened. The salt valve on the second salt box is opened and the charge is dropped from the evaporator into the second salt box as above described.

Drying and Removing Salt

The salt in the first box is now ready for drying. The salt box return line is open, thus connecting the bottom of the box with the body of the evaporator above the calandria. The vacuum breaker, which is a valve at the end of a nipple, is opened. This breaks vacuum or puts atmospheric pressure on the top of the salt and liquor in the salt box, whereas the bottom of the box is under vacuum through being connected into the evaporator which is under vacuum. The liquor mixed with the salt will draw through the salt and pass back into the evaporator body. It can be determined when the liquor is passing through by feeling of the salt return line, which becomes warm, or the level of the liquor may be seen in sight glasses in the salt box.

After the liquor starts to pass off from the salt box, the vacuum breaker is closed and steam is turned on

to the top of the salt. Enough steam is kept on to show a very low pressure on the box. After the liquor has all been drawn off into the evaporator body, steam is kept turned on for 15 to 30 minutes to dry the salt. When the salt is dry, steam is turned off and the valve on the salt box return line is closed. The salt box is now completely separated from the evaporator. The vacuum breaker is opened. The salt door is opened and the salt removed.

When the salt box is empty, the salt door is closed, and the valve on the salt box return line is opened very slowly to pull vacuum on the salt box so that it will be ready for dropping the next charge from the evaporator.

Concentrating and Finishing

The operation of filling and emptying the salt boxes is repeated as often as necessary until the half-crude stage of glycerine is reached. The half-crude stage is readily recognized, because at this time, maintaining the same level in the evaporator and the same amount of steam on the calandria, both the vacuum on the equipment and the pressure on the calandria tend to rise quite markedly. Steam is then gradually reduced until there is about 5 lb. of pressure on the condensation drain with but little steam turned on the calandria.

With these conditions obtaining and with one salt valve open, the feed to the evaporator is shut off and the charge in the evaporator is concentrated until the liquor has a temperature of about 165 deg. F. under 26 in. of vacuum, or 170 deg. F. under 25 in. of vacuum. The salt valve is closed and the charge in the evaporator is not dropped again. The salt box is steamed as usual and the charge in the evaporator is concentrated until it has a temperature of 200 deg. F. under not less than 27 in. of vacuum.

If the spent lye has been properly treated, this finishing condition will produce a crude glycerine containing in excess of 80 per cent glycerol. Analyses of the crude produced should be made from time to time and the finishing temperature decreased if possible, as there is some loss of glycerine when finishing at 200 deg. Good crude glycerine has been obtained with a finishing temperature of 170 deg. F.

Advantages of Evaporating Under Vacuum

Evaporation under vacuum is carried on primarily for the purpose of increasing the rate of evaporation and not for the saving of steam, as will be seen from the following:

Under atmospheric pressure, saturated steam has a total heat of 1150.4 B.t.u., while under 26.85 in. of vacuum it has a total heat of 1110.6 B.t.u. The difference in total heat is 39.8 B.t.u., or 3.46 per cent. The saving in heat units by evaporating under this vacuum is then 3.46 per cent, but against this saving there are the charges for steam consumed by the vacuum pump and also the condensing water required.

The advantages of evaporating spent lye under vacuum are primarily that to evaporate a given quantity of lye there is a saving in equipment and floor space required and also less loss of glycerine through being able to make crude glycerine at a lower temperature.

Rate of evaporation is approximately proportional to the difference in temperature between the heating medium and the medium being heated. Taking, then, the case of evaporating water on which accurate temperature figures are available,[1] assume the steam pressure on the calandria to be 5.3 lb., at which pressure the temperature of steam is 228 deg. F. Under atmospheric pressure the boiling point of water is 212 deg. F. and under 26.85 in. of vacuum the boiling point of water is 116 deg. F. Boiling under atmospheric pressure, the temperature drop would be 16 deg., whereas boiling under a vacuum of 26.85 in., the temperature drop would be 112 deg. F. Since the rate of evaporation is roughly proportional to the temperature drop, the rate of evaporation under the above vacuum would be about seven times as great as under atmospheric pressure.

Necessity for Avoiding Sudden Rise in Vacuum

Vacuum decreases the temperature at which a liquid will boil. In the case of water it will boil at a temperature as low as 32 deg. F. under perfect vacuum. This fact makes it very important that no sudden rise in vacuum take place in the evaporator.

If water is boiling in an evaporator under 20.04 in. of vacuum, its temperature is 161 deg. F. If the vacuum is 26.85 in., its boiling point is 116 deg. F. If there is present in the evaporator 2,000 lb. of water boiling under a vacuum of 20.04 in., the total number of B.t.u. present is 2,000 times 1129.9, or 2,259,800. The total amount of heat present in this amount of water under 26.85 in. of vacuum is 2,000 times 1110.6, or 2,221,200 B.t.u.

If the vacuum is suddenly increased from 20.04 in. to 26.85 in., water is present in the evaporator, which water has a boiling point of 116 deg. F. and the temperature of which is 161 deg. F. There is then available the difference between the two total heats, or 38,600 B.t.u., which energy very quickly expends itself in converting some of the water into steam. While the amount of steam generated with this excess of heat is only about 35 lb., yet this steam has a volume in excess of 6,000 cu.ft. which is generated suddenly throughout the 2,000 lb. of water and will mechanically carry over most of the water to a point beyond the evaporator. When the above conditions exist, the charge may be seen in the catchall, or if there is no efficient catchall, it may be seen in the discharge of the vacuum pump.

In a properly designed evaporator this is probably the most prolific source of glycerine losses. For this reason it is advisable to have all evaporators equipped with a recording gage (either thermometer or vacuum gage) so that there may be kept a check on how the evaporator is run for the full period of operation.

Entrainment Losses of Glycerine

Entrainment losses of glycerine usually consist in the passing over of small particles of the solution being evaporated. These extremely fine drops may pass from the surface of the boiling liquor as such or may be the result of breaking up of larger drops by impingement or the breaking of bubbles. It can be demonstrated mathematically that comparatively large drops of liquor may be carried away with the vapors from the glycerine evaporator.

Causes and Remedies for Decreased Rate of Evaporation

Decrease in the rate of evaporation of any given glycerine evaporator is most frequently due to the salt-

[1] Marks and Davis Steam Tables.

ing up of the tubes. This condition is largely a function of the design of the calandria and the salt content of the spent soap lye.

If there is a marked decrease in the rate of evaporation the manholes should be opened so that the calandria may be inspected. If the calandria is clean, the calandria and condensation drain should be tested under water pressure. If the calandria is salted, the manholes should be closed and the evaporator filled with water so that the calandria is completely immersed and this water boiled for about 15 minutes. It should then be drained into a storage tank so that the glycerine may be recovered. This water should be tested with a hydrometer and if it has a Baumé higher than 23 deg., it may be concluded that it is saturated with salt. A second charge of water should then be boiled and tested. If this second wash water tests less than 23 deg. Bé., this water should be run to waste. The manholes should be opened and the calandria examined to see if it is free from salt. It frequently happens that there is a small leakage in the steam valve on the calandria so that when the evaporator is shut down at night the salt deposit on the calandria and tubes is baked on very hard. Under these conditions, boiling with water for a short time will not dissolve all of the salt, so that the Baumé test may show the presence of only a small amount of salt in solution while the calandria is still coated. It is good practice to fill a glycerine evaporator with water when it is shut down for any considerable period of time. The necessity of doing this will vary in different soap works where different types of lye are handled and is a matter which can best be determined by experience.

The condensation drain of the evaporator should be equipped with a compound gage (pressure and vacuum) so that any leakage in the calandria may be easily detected. Small pinhole leaks usually can be located only by putting a water pressure test on the calandria.

Legal Notes

By Wellington Gustin

If Performance of Contract Is Impossible at Time Specified Both Parties Are Discharged

In Edward Maurer Co., Inc., vs. Tubeless Tire Co., 272 Fed., 990, plaintiff sued to recover damages for the refusal of defendant to accept and pay for certain rubber yet undelivered upon two contracts. The first contract was made May 3, 1918, and the second May 14, 1918, both covering 45 tons of rubber, deliveries to be in equal monthly installments from May to December, 1918.

About 21,000 lb. of rubber was shipped in May and June, 1918, which was accepted and paid for by defendant. On Sept. 27, 1918, plaintiff shipped 11,204 lb. more, which defendant refused to accept and which was afterward returned to plaintiff and resold by it at a loss of 4c. per lb. No further deliveries were made.

When the contracts were made both parties knew the United States contemplated fixing a maximum price for rubber and restricting its importation from overseas and that such regulations might be announced at any time. On May 7 these regulations were promulgated, whereby plaintiff was not permitted to import any new rubber for delivery under these contracts unless defendant obtained an allocation certificate from the War Industries Board authorizing the defendant to buy and use it.

The allocation of rubber among manufacturers was made on the basis of their consumption of rubber during the preceding year, and inasmuch as defendant's plant was during that period in the construction and experimental stage, defendant was able to have allocated only 180 lb. a month. Plaintiff depended on importation of rubber and therefore since it could not import it could not deliver to defendant. These restrictions were lifted Dec. 13, 1918, and by April, 1919, plaintiff had imported rubber and was then in a position to make further deliveries. Formal tender of delivery was made in June, 1919, and acceptance was then refused. At this time the price of rubber was 40c. per lb.—that is, 22c. less than the contract price. Suit was then brought to recover damages, measured by this difference between market price at time of tender and the contract price.

Plaintiff contended that these contracts, properly construed, merely postponed or suspended delivery during the period that performance was prevented by governmental interference and that when the restrictions were removed the contract remained in full force and effect, with an obligation upon the plaintiff thereafter to deliver, and upon the defendant to accept and pay. By provision in the contract it was "subject to all the rules and regulations imposed by the United States Government."

Government Regulations Voided Contract

The court said plaintiff's contention could not be sustained, since the contract in its entirety was made subject to the rules and regulations imposed by the United States Government. It is not deliveries only, but the contract obligation itself, which is made to depend upon these conditions.

Again the court points out that in contracts to deliver and to accept and pay for an article of commerce, the market value of which is fluctuating, time is an essential element. The failure or refusal of the seller to deliver or tender the monthly quantities at the time is a breach which would discharge the buyer from further obligation to accept and pay. The buyer of an article thus fluctuating in value cannot be held to an obligation to accept and pay at other times and under different conditions when its market value may have greatly changed.

The rule of law applicable is that if performance of the contract is made impossible by a subsequent valid act of law or governmental authority, both parties are discharged. If a contract is made subject in its entirety to a condition, and that condition happens, the rule is that both parties are discharged, and not that performance is suspended until the condition is overcome. The court says that neither party could have in mind merely a suspension or postponement of delivery during the war or while governmental regulations were in force, because no one could then foresee how long the war would continue, nor anticipate market or manufacturing conditions at the end of the war and after the restrictions were lifted. It would require clear and apt language in a contract before a court would be justified in finding such to be the intent of the contracting parties. Therefore the federal District Court gave judgment for the defendant.

Some Economic Aspects of Ammonia Oxidation*

Cost of Concentrating Weak Nitric Acid Produced by Ammonia Oxidation at Present More Than Offsets Advantages Due to Lower Conversion and Nitrogen Costs — An Economic Study of the Factors That Determine When Ammonia Can Profitably Replace Saltpeter as a Source of Nitric Acid

By GUY B. TAYLOR
Experimental Station, E. I. du Pont de Nemours & Co.

IF THE primary product obtained by oxidizing ammonia were strong nitric acid, then ammonia on a price parity basis with Chilean saltpeter would be incomparably cheaper than saltpeter as a source for nitric acid. Unfortunately the primary product is nitric oxide and the cost of conversion of this oxide of nitrogen into strong nitric acid is considerable, in spite of the fact that the raw materials, water and air, required for doing so, cost practically nothing. The industrial uses for weak nitric acid are so limited in extent that the oxidation of ammonia for the production of weak acid is of minor interest in the discussion. The question, then, of when it is economical to oxidize ammonia and when not to oxidize ammonia centers largely around the question of the cost of concentrating nitric acid. This state of affairs will continue as long as a small price differential exists between Chilean saltpeter nitrogen and ammonia nitrogen. With the development of processes for synthetic-ammonia manufacture, the price differential is likely to change in favor of ammonia and the relative importance of nitric-acid concentration will vary as a factor in the situation.

The next most important factor, after raw materials cost and concentration cost, is the scale upon which manufacture is conducted. Nitric acid is an extremely corrosive liquid and on this account its transport is difficult and expensive. As a consequence nearly all large users manufacture at the place of consumption. Ammonia oxidation plants are not inexpensive to build and the first cost per ton of rated capacity is naturally greater the smaller the output. It might pay to construct a new plant to produce nitric acid by oxidizing ammonia, while under a similar set of circumstances it would not pay to scrap a going retort process.

Comparison of Equipment and Manufacturing Processes

Before proceeding to more detailed comparisons, it is advisable to outline briefly the character of the plants required for the two processes. The essential units in the equipment are:

Ammonia Oxidation	Chilean Saltpeter
1. Ammonia liquor storage.	1. Soda storage.
2. Ammonia gas plant.	2. Sulphuric acid storage.
3. Ammonia converters.	3. Retorts.
4. Absorption system.	4. Condensers and receivers.
5. Nitric acid concentration.	5. Absorption system.

In the ammonia-oxidation plant ammonia gas is distilled from liquor and mixed with air. The gas mixture is then put through a catalyst in the converter whereby nitric oxide and water vapor are produced. The gas then passes to the absorption system, where, coming in contact with water and air, the nitrogen oxides are converted to weak nitric acid with a strength of about 50 per cent. This weak acid is converted to 90+ per cent HNO_3 by distillation from sulphuric acid. This results in the production of weak sulphuric acid, from which the water must be boiled out in order that it may be used again.

In the saltpeter process sodium nitrate and sulphuric acid are charged into cast-iron retorts and strong nitric acid is distilled out and condensed. Toward the end of the distillation the distillate weakens somewhat due to thermal decomposition of HNO_3 and the release of water from the charge, previously held by the sulphuric acid. This weaker distillate is in some cases caught in a separate receiver and in others mixed with the strong distillate. Some nitrogen peroxide is evolved and recovered as dilute acid in the absorption system. The dilute absorption system acid and the weak distillate together seldom amount to more than 10 per cent of the yield.

In the ammonia-oxidation process all of the output is recovered first as dilute acid, which must be concentrated, while in the saltpeter or retort process upward of 90 per cent of the output is directly recovered as strong acid. On the other hand, the retort process consumes sulphuric acid in about equal tonnage with Chilean saltpeter and the ammonia-oxidation process consumes none.[1]

Fixed Charges—Construction and Operation

As a basis of comparing the two processes let us take a case favorable to ammonia oxidation. Let us assume that a new plant for nitric-acid manufacture is to be built in a locality favorable to large-scale production, say a place where 25,000 tons of HNO_3 per year can be disposed of. This is a convenient capacity rating to assume, because it approaches the largest conceivable peace-time production in any one place and because a plant of this size was actually built in this country during the war (U. S. Nitrate Plant No. 1). This gives us a line on probable plant cost. Such a plant will cost, say, $1,000,000, or $40 per ton-year. The first cost of a retort plant on this scale will amount to, let us say, $12 per ton-year, or less than one-third as much. The cost of operating the two plants will vary from time to time, but our estimate is that this cost will average about the same for each—that is, $10 per ton of product figured as 100 per cent HNO_3. This item, hereafter designated "operating cost," includes operating labor, repair labor, repair material and replacement, fuel and power, and superintendence. In the case of the ammonia-oxidation process the operat-

*A paper presented before the Acid Symposium at the fourteenth semi-annual meeting of the American Institute of Chemical Engineers, Niagara Falls, Canada, June 19 to 22, 1922.

[1]Except the small quantity lost in repeated reconcentration of sulphuric acid required for dehydrating weak nitric acid.

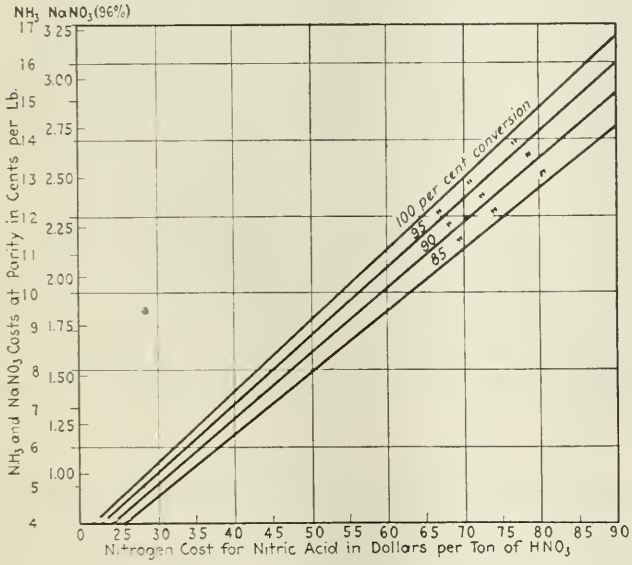
ing cost of the concentration unit is excluded. The retort process requires about 1.4 tons of sulphuric acid per ton HNO_3. If this acid costs $16 per ton, the sulphuric acid cost per ton of HNO_3 will be about $20, making due allowance for niter cake credit.

In order to eliminate what may be termed the minor variables in the problem, let us assume the cost factors arrived at above are constants and study the major variables—nitrogen costs, yields and concentration costs. The assumed constants may then be summed up as follows and the sum designated "conversion cost":

	Ammonia Oxidation (As 50 Per Cent Acid)	Chilean Saltpeter (As 90+ Per Cent Acid)
Operating cost	$10	$10
Fixed charges at 15 per cent[2]	6	2
Sulphuric acid	0	20
Conversion cost, per ton of HNO_3	$16	$32

Nitrogen Costs

In the chart shown in Fig. 1 the relations between the nitrogen costs of the raw materials and the finished product for various conversion efficiencies are presented graphically. The ordinate shows the costs of ammonia and sodium nitrate at parity in cents per pound and the



NH3 NaNO3(96%)
NH3 and NaNO3 Costs at Parity in Cents per Lb.
Nitrogen Cost for Nitric Acid in Dollars per Ton of HNO3
100 per cent conversion
95 " "
90 " "
85 " "
0 25 30 35 40 45 50 55 60 65 70 75 80 85 90

FIG. 1—NITROGEN COST OF NITRIC ACID VS. THE COST OF AMMONIA AND SODIUM NITRATE FOR VARIOUS CONVERSION EFFICIENCIES

abscissa the corresponding nitrogen cost for nitric acid in dollars per ton of HNO_3 at various conversion efficiencies. The nitrate is figured as 96 per cent pure.

The yield from nitrate may be conservatively put at 98 per cent and that from ammonia at 90 per cent (95 per cent oxidation efficiency and 95 per cent absorption efficiency). At these yields, with ammonia and nitrate at parity, and varying in price from 8c. to 15c. for NH_3 and 1.5c. to 2.9c. for nitrate, the total cost for nitric acid from ammonia varies from $64 to $106 per ton and for nitrate from $76 to $115 per ton. The spread between the two processes is only $12 at the lower nitrogen cost and $9 at the higher. That is to say, if 50 per cent nitric acid can be concentrated for much less than $10 per ton, it pays to oxidize ammonia when ammonia and nitrate costs are on a parity basis.

[2]Includes the items of taxes, insurance, interest, amortization and obsolescence.

The following tabulation gives a few examples of the spread between the two processes when nitrogen costs are not on a parity basis:

Cost of NH_3 Per Lb.	Cost of $NaNO_3$ Per Lb.	Ammonia Oxidation Cost of HNO_3 Per Ton (50 Per Cent)	Chilean Saltpeter Cost of HNO_3 Per Ton (90+ Per Cent)
8c.	1.75c.	$64	$82
10	2.25	76	97
12	2.50	88	103
12 5	2.25	91	97

The first three cases in the above tabulation are taken at prices showing not unusual disparities in price quotations between ammonia and nitrate, and in favor of ammonia. In the last case, ammonia is relatively the higher priced and is about the condition of affairs that obtained in the early months of this year. From the above it will be observed that ammonia as a source of weak nitric acid is cheaper than saltpeter at any disparity in nitrogen cost that is likely to occur.

It is doubtful whether the overall yield of an ammonia-oxidation plant can ever closely approach the efficiency of the retort process, which in well-conducted works averages 98 to 99 per cent. The catalytic oxidation efficiency to be expected under the best conditions can scarcely be more than 95 per cent and absorption efficiency 98 per cent, or an overall of 93 per cent. On a nitrogen parity, then, nitrogen for the ammonia-oxidation plant must always cost more, but this is more than balanced by sulphuric acid used in the retort process. As a matter of fact, based on prices in normal years, the nitrogen costs of the two processes would have been about the same in the past, because ammonia commanded a less price per pound of nitrogen than did nitrate. The thing to be emphasized in considering yield is the relative importance of yield gains to any probable operating economies. An addition of 1 per cent to the yield means more in dollars and cents than a reduction of 10 per cent in operation cost or fixed charges.

Costs of Concentration

The concentration cost, the most important item under present conditions militating against any widespread adoption of ammonia oxidation, is a difficult matter to estimate. Nitric acid has never been concentrated in this country on the scale assumed in our comparisons, except under war conditions. The cost of this operation will probably lie between $20 and $40 per ton of HNO_3. Assuming that it can be done for the lower figure, what price can we afford to pay for ammonia in order to compete with Chilean saltpeter? In the following tabulation the first column shows an assumed price for saltpeter, the second column the corresponding cost of ammonia at parity, the third column the price to which ammonia would have to fall to break even with saltpeter, and the fourth the estimated cost of nitric acid at the break-even condition. Yield from nitrate is taken at 98 per cent and from ammonia at 90 per cent. The conversion cost of ammonia is taken at $16 and of nitrate $32 per ton HNO_3; $20 is added to the ammonia-oxidation process for concentration.

Cost of Chilean Saltpeter, Cents Per Lb.	Cost of Ammonia—At Parity, Cents Per Lb.	Cost of Ammonia—Competing Price, Cents Per Lb.	Cost of HNO_3 Dollars Per Ton
2.0	10.5	8.8	89.00
2.5	13.0	11.2	103.50
3.0	15.6	13.7	118 00

The above tabulation shows that ammonia must be obtainable for at least 2c. per lb. less than the parity price in order to show any considerable saving over Chilean saltpeter at 2c. to 3c. per lb. as a source for strong nitric acid.

The catalytic oxidation of ammonia gas to nitric oxide—that is, the ammonia-conversion step in the process—may be considered as in a very satisfactory state. Obviously, from what has been said above, the point of attack in improving the process is to solve the problem of more cheaply converting nitrogen oxides to concentrated nitric acid. Seventy per cent of the plant cost is swallowed up in huge absorption towers recovering weak acid. And this weak acid must be concentrated. This problem in connection with the arc process, in which these features are greatly magnified, has received much attention abroad, as witnessed by an extensive patent literature. But not one of these proposals looks promising even on paper, and needless to say none has ever reached the commercial stage of development.

Conclusions

All things considered, it may be concluded as a result of this study that under present conditions, as a source for strong nitric acid, saltpeter has a slight advantage over ammonia. The conversion cost and the nitrogen cost (usually) of ammonia are less than corresponding costs of sodium nitrate, but this advantage is more than offset by the necessity for concentrating nitric acid in the ammonia process. The advantage of the retort process probably increases as the scale of manufacture decreases. If the price of ammonia falls, as is likely with the coming into production of synthetic-ammonia plants on a large scale, then the slight advantage of the retort process will disappear. It is conceivable that the time may come when it will no longer pay to import Chilean saltpeter at all as a source of nitric acid.[3]

There are two uses for which ammonia oxidation may be profitably employed immediately. In the writer's opinion all lead chamber or "nitration" sulphuric acid plants should be equipped with ammonia converters. In this case the plant investment is relatively small. The nitrogen oxides are used as such, no absorption system of any kind being needed. The ease of control and uniformity of supply ought to be of considerable advantage to the sulphuric acid plant operation. The second possible immediate use for ammonia oxidation is for the production of weak nitric acid. There are a few industries utilizing weak acid having no use for strong acid. If the requirements are sufficiently large, it would pay to oxidize ammonia.

[3]In this connection it should be remembered that the export duty on Chilean saltpeter from Chile is a considerable fraction of its total cost. This tax will no doubt be reduced to meet competition with ammonia, should the market for saltpeter be seriously threatened.

Hydro-electric Development in Italy

Hydro-electric power in Italy as of Jan. 1, 1922, is reported by Consul Sycks, Turin, as 1,191,797 hp. In addition to the hydro-electric plants now in operation, new ones are in course of construction, of which those in Lombardy will produce 121,934 hp. and those nearing completion in Piedmont will produce 109,386 hp. The total electric power now generated by the hydro-electric plants (1,191,797 hp.) is estimated at 60 per cent of the capacity of the total number of centrals for which concessions have been granted.

The Application of Chemical Research to the Cotton Oil Industry*

By David Wesson
Technical Director, Southern Cotton Oil Co.

During the past forty years accumulated experience aided by scientific research has brought about enormous changes in the milling of cotton seed and the refining of cottonseed oil. A knowledge of the fundamental principles of refining and hydrogenation has replaced the irregular evil-flavored oils of the early days with tasteless, odorless products which have taken much of the prestige from the oil of the olive and the fat of the hog.

Although much has been learned, let us not for a moment imagine that there are no new fields to conquer. We should know the breeds of cotton producing the seed which will carry the longest fibers and at the same time yield the most oil. We know that cake and meal are rich in protein, but we know comparatively little about the protein itself. Cottonseed oil has been bleached for the last forty years with fullers earth. How much do we know about why the earth does the bleaching and what is its effect on the oil itself? What is the nature of the color removed by the earth? How much do we know about the various mixed glycerides produced at different stages of the hydrogenation process? We know that all fats turn rancid, but we know very little about the causes and the products formed in the process. This is a matter of great practical importance.

In buying and selling crude oil our transactions are governed by a rule-of-thumb test which, in a way, approximates the time-honored but barbarous means employed in the refining kettle.

One of the most promising signs for the future is the spirit of the Department of Agriculture, which has started in on a fundamental research primarily to benefit the farmer, but incidentally of great use to the vegetable oil industry.

It seems to me that the time is ripe for co-operative research for the good of the industry as a whole. The day has gone by when there is anything to be gained by a lot of technical men getting together and all keeping their mouths shut for fear they might tell something that would be of use to the other fellow. A free interchange of ideas will, in my opinion, do more good to the industry as a whole than the past practice of silence and secrecy. There should be free converse about the chemical nature and the constitution of the materials which we all handle, but when it comes to the details of erecting and operating plants to obtain certain results, then we are treading on dangerous ground, and it is only right and proper to maintain secrecy.

*Extracts from an address before the thirteenth convention of the American Oil Chemists Society, New Orleans, June 5 and 6, 1922.

Revised List of Research Chemicals

The National Research Council has issued a new edition of its circular "American Research Chemicals" giving a more complete listing of the companies manufacturing research chemicals, biological stains and indicators, vital stains and hydrogen ion indicators. This list gives for each chemical the names of the companies which have reported to the committee that they are manufacturing that product. In a few cases distributors are also listed. A copy of the list can be obtained on application to C. J. West, National Research Council, Washington.

Fire Hazards at Quenching Tanks

AN IMPORTANT report from the committee on manufacturing risks and special hazards was considered at the May meeting of the National Fire Protection Association, on the "Regulations for Use of Volatiles in Manufacturing Processes." In introducing its report the committee states:

> The use of dip tanks containing highly flammable compounds subject to flashing at ordinary temperatures and giving off flammable vapors and possibly vapors forming explosive mixtures presents a severe fire hazard. Manufacturing requirements in some industries, the automobile industry for example, involve extremely large tanks, there being often three or four of them in a single room, each having a capacity of possibly 10,000 gal. The mixtures found in dip tanks may include various amounts of naphtha, benzine, benzene, amyl acetate, bisulphide of carbon, alcohol, which represent the principal flammable liquids. Of a slightly less hazardous nature are tanks containing paints, turpentine, kerosene, heated asphaltum, paraffine and tempering oils. Tanks containing mixtures with more or less benzine and naphtha represent a large majority of those in use.

Samples of air taken from dip and quenching rooms seldom show a content of volatile hydrocarbons which approach the point where danger from explosion exists. However, it is essential that means be provided to prevent the accumulation of heavy vapors at low points in the room; for somewhere between the rich, low-lying mixtures and the lean upper layers is an exact proportion which will explode from a small spark or flame. Furthermore, ventilation should be directed to the outside air; otherwise dangerous concentrations will occur in passageways leading to other rooms which act as ventilating corridors.

Dipping Room Fires Difficult to Extinguish

The fire hazard in dipping rooms is extreme in any case, as the nature of the compounds in the dip tanks is such that a fire in them produces serious results. Ordinary methods of extinguishment cannot often be applied with success to such a fire. Even if the room is fire resistive and contains no other combustibles, the heat from the burning compounds will ordinarily cause a severe loss to the most superior construction and even complete destruction has sometimes occurred. Such a fire will distort, with large loss, unprotected steel work and machinery in the room, as well as cause a heavy damage to the other contents.

Moreover, a dip tank on fire will burn for a very long time because a sufficient amount of air cannot get to the limited surface to consume the contents quickly. A tank containing an ordinary mixture, 2 ft. deep, would probably burn fiercely for 2 or 3 hours. The only way to extinguish such a fire is to smother it promptly. If too much water is applied to the tanks they will overflow and the burning volatiles will flow around the room wherever the water carrying the burning liquid on its surface may run, thereby spreading the fire. Provision for the safe disposal of the liquids is essential where water is likely to be used.

Hose Streams Spread Fire

The use of hose streams in rooms containing uncovered and unsecured tanks on fire has resulted in serious losses through the displacement of the burning liquids by the water, the heavy streams often splashing the liquid about the room and upsetting the containers. Too much care cannot be taken in using hose lines on such fires. There are a great many cases in the fire record where the light spray from the sprinklers has extinguished fires in open dip tanks, which effect has been largely due to the cooling power of the sprinkler spray, but even with sprinklers there is a danger of seriously overflowing the tanks. If hose streams are used, effort should be made to spray the water and confine work to cooling the building until the contents of the tanks burn.

Regulations Recommended

Section 4, on quenching tanks, proceeds:

> Where a continuous process tempering machine is used, pumps or other means shall be provided for circulating the oil from the tempering tank to the cooling tank, sufficient pumping capacity and the relations of the speed of the machinery to be so adjusted as to prevent the oil rising to a temperature dangerously near its flash point. An automatic cooling or refrigerating system arranged to regulate the temperature of the oil exactly is preferred. Automatic machines feeding hot parts to the oil preferably should be so arranged that they will stop automatically through the operation of a thermostat placed in the oil when dangerous temperatures are reached.
>
> Hot oil tanks, unless located under a very high or fire-resistive ceiling, should be provided with a noncombustible hood and tube passing to outside the building to serve as a vent in case of fire. In some cases a fan may be necessary, but its use should be avoided where adequate ventilation otherwise can be obtained. Care should be taken in providing such a hood to minimize interference with the protection of the building by hose streams and the hood should be slightly larger than the tank to shed from the oil tank water so applied. All such tubes should be treated as flues and kept well away from flammable roofs or other combustibles.
>
> Tanks shall not be located on or near combustible floors. Combustible stock and other combustible materials should be kept well away from them. Door sills into other rooms, if near, should be raised to prevent the flow of oil or water carrying burning oil through them, except that this provision may be waived when floors are provided with otherwise adequate drainage. Tanks shall be located a safe distance from furnaces or other such hazards likely to flash fire to the tank or its vapors.
>
> Overflow pipe shall be provided to prevent the oil rising to a point nearer than 4 in. of the top of the tank and a drain should be provided at the bottom of the tank. These may be combined with the circulating system if desired or arranged independently, to drain the oil to a safe place.
>
> The inspection department having jurisdiction shall be consulted as to whether the valve in the drain shall be operated automatically with approved heat release devices or manually, and if the latter, whether the valve should be arranged for operation from a distance.
>
> Inspection departments having jurisdiction shall be consulted as to whether standard automatic means for extinguishment should be provided and whether automatic should be combined with manually operated devices. If automatic foam extinguishing systems are used, they should be standard.
>
> An approved 40-gal. foam type extinguisher on wheels and other standard first aid apparatus should be provided.

Natural Sodium Compounds and Borates in 1921

The production of natural sodium compounds in the United States in 1921 amounted to 25,000 short tons valued at $894,000. This was a decrease of about 41 per cent in both quantity and value from the 1920 figures. The material was marketed as the carbonate, bicarbonate, sulphate and borate and as trona, a double salt of carbonate and bicarbonate.

The production of boron ores in 1921 was approximately 50,000 short tons valued at $1,320,000 and marketed as borax and colemanite. This represents a decrease of over 58 per cent from the quantity shipped in 1920.

Cleveland Meeting, National Lime Association

Varied Technical Program Covers All Phases of Association Activities—Experience With Mount Kilns at Rockland, Me.—Lime Burning in Rotary Kilns—Symposium on Lime for Chemical Industries—Effect of Lime in Concrete—Work of the Chemical Department

IN OPENING the fourth annual convention of the National Lime Association, at the Hotel Statler, Cleveland, June 13, President Charles Warner said that from one point of view it was fortunate that the industry did not comprise thousands of producers, for it enabled the members to get together in a way which would not be possible in a large organization. This spirit of good fellowship was manifest throughout the various phases of the convention activities.

In addition to the technical program, some features of which are noted below, there were inspiring luncheon addresses by Hon. Newton D. Baker, former Secretary of War, H. Elmo Martin and George A. Coulton, vice-president of the Union Trust Co., Cleveland.

Experience With Mount Kilns at Rockland, Me.

Successful operation for nearly a year has served to dispel the skepticism regarding the Rockland & Rockport Lime Corporation's venture at Rockland, Me. The battery of six continuous-discharge vertical Mount kilns has proved to be nearly automatic, only 10 men being required for 24-hr. operation—3 foremen, 3 gas producer tenders, 2 skip operators and 2 handy men (day only). It has been found possible to produce 125 to 130 tons per day of 24 hr. with 5 kilns.

As would naturally be expected, experience developed the desirability of making certain changes in the original plans. Some of the more important of these were discussed and illustrated by N. L. Rockwood, editor of *Rock Products*.

In order to study the action of different sizes of stone in the kilns, the shaking grizzly has been replaced by a revolving screen giving four sizes. It was found necessary to design special bin gates to withstand the rough service in feeding the kiln-charging skips. The two suction fans on top of the kilns did not maintain sufficient draft and they were temporarily speeded up to twice their normal capacity but are now being replaced by larger fans. With these it will be possible to control the burning by regulating a draft damper.

An average of 6 tons of lime is produced per ton of coal, including that used under the boilers. Lime is discharged practically cold while the flue gas temperature is only 250 deg. C. Water used for cooling the gas valves goes to the boilers.

In effect this plant is a huge laboratory for the lime industry, where the effects of various factors can be determined under operating conditions.

Lime Burning in Rotary Kilns

Problems encountered in attempting to burn lime in rotary kilns were considered in a very comprehensive manner by Irving Warner, plants manager, Charles Warner Co. Because of different conditions, it is not possible to follow cement mill practice too closely and yet it is difficult to determine the proper modifications because of the limited number of rotary kilns in the lime industry. The capacity of this type of kiln is so great that few lime manufacturers have more than one, with the result that experimental work is very limited. With only one kiln, heat recovery systems are hardly profitable and the same may be said of separate powdered coal systems, such as are found in cement mills. There are on the market self-contained powdered coal units which could be used with a single kiln and it is planned to install one of these in connection with the 8 x 150 ft. rotary at the Cedar Hollow plant, which is now using excess producer gas from the Mount kiln unit.

Small stone (from $\frac{1}{4}$ to $\frac{5}{8}$ in.) was found to work best, although in order to avoid crushing the kiln is actually run on $\frac{5}{8}$- to $1\frac{1}{4}$-in. stone. A constant ratio should be maintained between the feed and the speed of the kiln. For controlling the latter a variable speed motor may be used. The inclination of the kiln under discussion was $\frac{3}{4}$-in. per ft. but $\frac{1}{2}$- to $\frac{5}{8}$-in. is better, since a greater inclination cuts down speed and agitation of the charge.

In discussion it was brought out that while silica brick work very well in Mount kilns, they cannot be used in the rotary type because of the tendency to spall, the high heat conductivity which would increase radiation losses and the high coefficient of expansion.

Symposium on Lime for Chemical Industries

Parts of the Thursday afternoon and Friday morning sessions were devoted to very practical and instructive

discussions of the application of lime in several branches of the chemical industry.

Paper Pulp and Glass

Data on the use of lime in the preparation of cooking acid for sulphite pulp were presented by P. A. Paulson, consulting engineer, Appleton, Wis.

In liberating cellulose from wood by treatment with acids, many of the inorganic acids yield insoluble, dark-colored decomposition products. When compounds such as calcium and magnesium bisulphites are used, this difficulty is overcome, as the decomposition products remain in solution. Two systems are employed for making the cooking acid—the milk-of-lime and the tower. In the former, high-magnesia lime is slaked, made up to a 1 deg. Bé. milk of lime and saturated with sulphur dioxide. In the latter, high-calcium limestone is placed in a tower through which water and sulphur dioxide pass counter-currently, the cooking acid being removed at the base of the tower. The two bisulphites differ somewhat in their action. Calcium bisulphite is unstable when heated, forming a precipitate of calcium sulphite, and tends to give a harsh transparent pulp. The magnesium salt is more stable so that the liberation of SO_2 during the cooking is more gradual. The resulting pulp is softer, whiter and purer. For these reasons many mills prefer to use a cooking acid containing both bisulphites.

R. P. Shiveley, of the Monongah Glass Co., outlined briefly the uses of lime in the glass industry. Constant physical properties are required in glass for use on machines, since the machines cannot allow for variations as did the hand operators. Also producer gas is less uniform than the natural gas formerly used, so that more attention must be paid to the uniformity of raw materials. Limestone, quicklime and hydrated lime are used, the former being cheaper but more difficult to melt than either quicklime or hydrate. As a rule, high magnesia content is desirable for pressed glass while blown glass requires high-calcium lime.

Causticizing problems were taken up by G. K. Spence, chief chemist, New York and Pennsylvania Paper Co., Johnsonburg, Pa. Waste of time and material is now avoided by testing each shipment for active CaO before acceptance. The lime should contain not less than 90 per cent active CaO nor more than 1½ per cent MgO or SiO_2. Sludge is being reburned or dried for use as agricultural lime or whiting.

Water Softening

A paper by S. C. Hadden, editor of *Municipal & County Engineering*, was read by G. J. Fink. It was a strong plea for the centralized softening of public water supplies. The lime-soda ash process is about the only one available for whole municipalities. After-deposits can be eliminated if the filtration plant is properly designed. From data on 338 municipalities in Illinois, a conservative estimate of the amount of lime which could be used throughout the country is 1.000,000 tons per year, which contrasted with the present 30,000 tons indicates a market only 3 per cent developed.

Textile Industry

Opportunities for increased use of lime in the textile industry were indicated by Prof. Elton R. Darling, of James Millikin University. In boiling-out in closed kilns, lime has many advantages over caustic soda. It gives an even boil, leaves the goods with a proper bottom for sizing and completely removes the waxy materials by its combined saponifying and emulsifying action. If lime could be substituted for caustic soda wherever it would be advantageous to do so, it is estimated that the increased demand for lime would amount to about 200,000 tons a year.

Effect of Lime in Concrete

W. E. Emley, of the Bureau of Standards, summarized some very important findings on the effect of adding lime to concrete. Additions of 5, 10 and 15 per cent of hydrated lime were made to the following concretes: 1:1½:3; 1:2:4; 1:2½:5; 1:3:6. Different amounts of water were added and compressive strength and flow plotted against per cent water by weight. Results may be summarized as follows: If water is added to a given concrete, but no lime, the flow increases while the strength decreases; if lime is added but no water, flow decreases while strength increases. The effect depends also upon the properties of the original concrete and the net effect of adding both water and lime may be plus, minus or zero.

Interesting Properties of Lime

Prof. F. C. Mathers, of the University of Indiana, made some interesting observations on the effect of addition agents on the slaking time and on the rate of settling of hydrate. Thus, 5 per cent HCl decreased the slaking time from 12 min. to ⅓ min., while a small amount of sugar in the water used for slaking increased the time to 2 hrs. Similarly, sugar decreases the rate of settling of hydrate while $CaCl_2$ hastens settling.

When hydrated lime is reburned at 840 deg. F., a very active form of lime results. The addition agents noted above are without effect upon it. It would seem to be very effective for the preparation of absolute alcohol as it combines almost instantly with the water in 95 per cent alcohol.

Value of Research to Industrial Associations

In discussing the value of research to industrial associations, E. R. Weidlein, director of Mellon Institute, emphasized the fact that America now leads the world in the application of science to industry and that this is due in no small measure to the tendency away from the secrecy which formerly surrounded industrial developments.

A centralized research laboratory maintained by an association is particularly valuable to the small manufacturer and it also prevents much unnecessary repetition. It should function to create improvements in technical processes, to disseminate the knowledge thus obtained and to maintain systematic co-operation through contact with other branches of industry. A fact which should not be lost sight of is that both labor and capital benefit from improvements in technology, for if a product is made cheaper the demand increases, while if it is made better, new markets are attracted.

Officers for Next Year

The following officers were elected to serve for the year 1922 to 1923: President, Charles Warner, of Charles Warner Co., Wilmington, Del. and Philadelphia, Pa.; vice-president, George Nicholson; treasurer, Milton McDermott; secretary and general manager, N. G. Phillips. The following division managers were appointed: Agricultural division, J. A. Slipher; construction division, W. A. Freret; chemical division, M. A. Holmes.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

American Potash Now Said to Meet Government Purity Standard

American potash is now of a degree of purity well within the standard set by the United States Department of Agriculture, according to a statement by the Bureau of Soils. Under the present method of producing potash at Searles Lake, Cal., there no longer exists the former danger to crops from the presence of borax in the fertilizer.

The department has followed closely the course of American potash production, not only with a view to assisting in establishing commercial sources of potash but also to maintaining a quality that would be suitable for use as fertilizer without fear of injury to crops. During the summer of 1919, the attention of the department was directed to injury to crops by the use of fertilizers. The injury was widespread and serious especially to the tobacco and cotton crops of the eastern districts of North and South Carolina and to the Maine potato crop.

The discovery of the ill effects of borax led the department to issue an order limiting the amount of borax that could be present in a mixed fertilizer, unless specifically labeled, to an amount that would be equivalent to not more than 2 lb. per acre in the applications used by the growers. The department also forbade the sale to farmers, as straight goods, of potash salts containing more than ½ of 1 per cent of anhydrous borax.

As originally obtained by the producers, the potash salts which were the cause of crop injury ranged in content of borax from 4 to 14 per cent. Immediate steps were taken to improve the methods of recovery and to eliminate the borax as far as practicable. The results of the refinement of methods show that it is practicable to produce potash salts from the Searles Lake brine with a borax content well within the limit of safety set by the department. Analyses show that in the salts produced during the period 1920 to 1922 the borax content ranged from 0.27 to 0.50 per cent, which compares favorably with the content of borax in sodium nitrate.

Bounty for Domestic Potash Agreeable to Producers

Opposition from the farmers to the proposed duties on potash has been an important factor in inducing the Finance Committee of the Senate to revise further the tariff bill by placing potash on the free list and bringing in a proposal for a bounty which would offer a financial encouragement to the American industry equivalent to the protection carried in the bill passed by the House.

Chairman McCumber, of the Finance Committee, pointed out that if the bounty were made effective today, nothing would be paid out, as he says there is no potash being produced domestically. Even during the height of the war when potash rose to $450 per ton, the maximum production was 54,000 tons, he pointed out. If the domestic production were to reach 50,000 tons a year during the 5-year period over which the bounty would apply, bounty payments would not exceed $2,500,000 for the first year; $2,500,000 for the second year; $2,000,000 for the third year; $1,500,000 for the fourth year and $1,000,000 for the fifth year.

The representatives in Washington of the domestic industry seem to be entirely willing to accept the bounty proposal, but it is predicted in some quarters that the attitude of the potash producers will change. This is based largely on the experience with the sugar bounty. A direct payment of public money to an industry seems to arouse much greater resentment than does the payment of even a larger amount of tax at the custom house.

Delay of Dye Embargo Vote Pleases Opponents

Consideration by the Senate of the naval appropriation bill and debate on the policy with regard to soldiers' bonus had the effect of displacing the tariff bill during the greater portion of the past week and as a consequence the vote on the dye embargo was deferred.

There is increased reason to believe that the embargo proposal has the support of sufficient votes to secure its adoption. This practically has been admitted by its opponents and their policy is to delay its consideration as long as possible in the hope that something may happen to make the plan less popular.

Latest Muscle Shoals Minority Report Augments Growing Opposition to Ford Proposal

Since the introduction of bills more than two weeks ago, emanating from the Committee on Military Affairs of the House of Representatives, proposing the acceptance of Henry Ford's offer for the government Muscle Shoals properties in one case and the acceptance of the offer minus the Gorgas steam plant in the other, the matter of a Muscle Shoals policy has been uppermost in the minds of the majority leaders in each House. No formal announcement has been made but it is believed that they oppose any vote on the proposition at this time.

During the two weeks that members of Congress have had in their hands the reports of three groups within the Military Affairs Committee, the opposition to the acceptance of the Ford offer has grown steadily. This trend was augmented greatly when Representative Kearns of Ohio brought out another minority report signed by seven of his colleagues on the Military Affairs Committee. This report assails the Ford offer in vigorous fashion. "If we were believers in fables, or had faith to believe in the pranks of fairies," says this report, "then we might think Mr. Ford is the reincarnation of Alladin plus his lamp."

Weeks Displeased With Fertilizer Clause

Emphasis is laid on the fertilizer feature of the Ford offer in this report. It points out the fact that Mr. Ford has always refused to allow himself or his company to be bound without qualification to the continuous manufacture of fertilizer at Muscle Shoals, provided this plant is turned over to him. It recalls the testimony of Secretary Weeks before the committee in which the War Secretary stated that Mr. Ford had flatly refused to guarantee to continue to manufacture fertilizer during the life of the contract. Moreover, the manufacturer let it be distinctly understood that he would stop the manufacture of fertilizer if he could not make it profitably. The report points out that the precise meaning of "profitably" is unknown. Because of this frank admission and many kindred statements, continues the report, Secretary Weeks was entirely dipleased with the language in the so-called fertilizer clause in the Ford offer. Later testimony in support of the fertilizer clause does not change his attitude.

Report Points Out Jokers in Fertilizer Provisions

The report acknowledges that a great part of the farm lands of the United States is in great need of plant food and that Congress would be justified in departing from its old policies and traveling a long way to assist in getting fertilizers cheaply for the farmers. It is felt, however, that the Ford offer is a hollow promise made to enlist the support of the farmers and not absolutely binding on any fact contained in the contract or existing outside of the contract. These statements are made and sent broadcast throughout

the country without regard to truth. The bold declaration is made that Mr. Ford will manufacture fertilizer at the Muscle Shoals plant and bring down the price one-half. Nothing is ever said that the principal business of Mr. Ford—should he get this gigantic plant—would be the manufacturing of other articles which he would be allowed to sell at any price that he might see fit. The only thing that is kept before the public is that he is to make fertilizer and sell it cheaply to the farmer, only charging for himself a profit of 8 per cent on the production. No one has ever suggested how he could make fertilizers and sell them cheaply or what means he would employ. The bold claim is made and Congress and the country must take the statement as absolute truth or be forever condemned by this crowd of wicked propagandists.

While the minority headed by Mr. Kearns points out the comparative advantages which would come from the distribution of this power by the Alabama Power Co., subject as it is to the control of public utilities commissions, the acceptance of that company's offer is not recommended. On the contrary, it is suggested that the government should complete the dams and that the Secretary of War should call for new bids with the understanding that neither of the nitrate plants is to be sold. If these were leased along with the dam, it is pointed out that the government could exercise control and regulation.

Agricultural Interests Back Ford

The American Farm Bureau Federation in a formal statement reiterates its statement that the acceptance of the Ford offer means that there will be reasonable expectation that fertilizers will be produced at Muscle Shoals and delivered to the farmer for about one-half what he would pay for them otherwise.

The Farm Bureau Federation, which is the largest of the national organizations of farmers, also denounces in no uncertain terms the minority report submitted by Representative Kearns. The statement says in part:

"We resent the statement that the Ford offer contemplates a fraud. It seems to be the familiar cry of 'stop thief!' while the selfish interests get away with the goods.

"We have studied this Muscle Shoals project and have investigated it carefully from every angle. The farmer well knows what can be done at Muscle Shoals under the Ford plan and does not need the protection of self-appointed guardians from the big fertilizer distributing centers and those who represent the selfish interest groups in the upper eastern section of the country, a section which, although it raises but one week's supply of cereal and meat for itself continually has undertaken to block the farmer in his efforts to secure cheaper food production and better living conditions.

"In the matter of fertilizer production at Muscle Shoals, the farmers need no such experts to advise them as Hugh L. Cooper, who represents the du Pont interests, the Aluminum Company of America and the General Electric Company."

Would Make Appropriation Contingent on Acceptance of Offer

When the $7,500,000 appropriation comes to a vote in the House, an effort will be made to attach a condition that it will not become available until the Ford offer either has been accepted or rejected. The idea is that if the Ford offer is accepted, then the appropriation should be applied under the terms of that proposition. If the Ford plan should be rejected an effort will be made to condition the appropriation so that it may be applied under the plan for government operation.

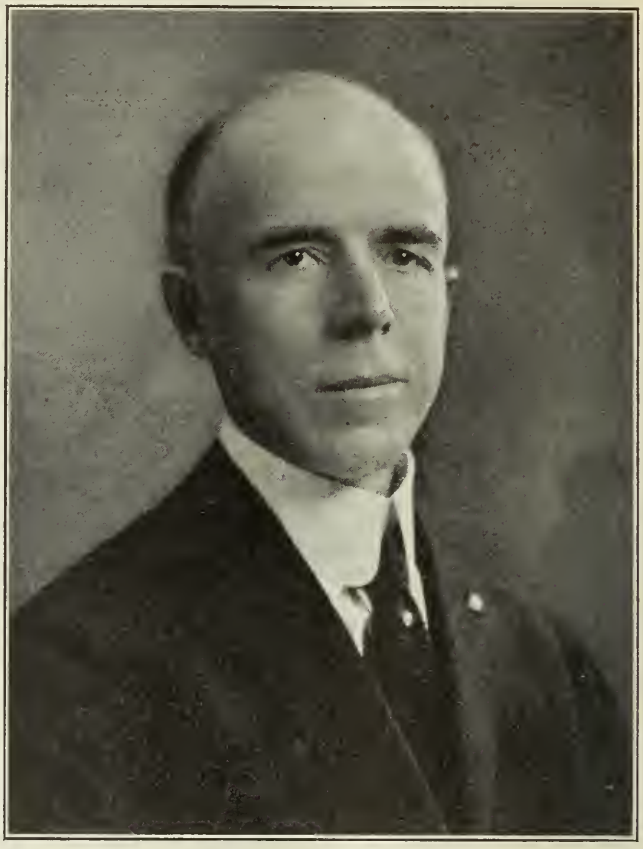
Chemical Warfare Service Granted Increase in Appropriation

An appropriation of $600,000 for the Chemical Warfare Service for the next fiscal year was agreed upon by the conferees on the War Department appropriation bill on June 22. It will be remembered that the bill as passed by the House carried $500,000 for the Chemical Warfare Service. This amount was raised by the Senate to $750,000. The compromise figure of $600,000 was decided upon after an extended discussion.

Plans Maturing for Pittsburgh Meeting of American Chemical Society

Preliminary plans for the Pittsburgh meeting of the American Chemical Society have been announced by the local section. It is expected that the convention will bring about 2,000 visitors to the steel city September 4 to 9.

James O. Handy, director of the Pittsburgh Testing Laboratory, is chairman of the Pittsburgh Section of the Society and is actively engaged in arranging the details



JAMES O. HANDY

of the meetings and entertainment features that are scheduled as features of the convention. The Council meeting will be held Monday, Sept. 4, followed by a dinner at the Duquesne Club and a theater party. The first general meeting will be at Carnegie Music Hall on Tuesday morning. Scientific papers of general interest to chemists and the public and several addresses by officials will be given. The general meeting will be continued in the afternoon and followed by a smoker at Syria Mosque in the evening.

Divisional and sectional meetings will begin on Wednesday and will continue through Thursday. A large number of papers have already been scheduled for the technical sessions. The public meeting, which is to be held in Carnegie Music Hall, will be featured by the address of Edgar F. Smith, president of the Society. Friday will be devoted to excursions to industrial plants in the vicinity of Pittsburgh. Plans are also under way for social features and entertainment of visiting ladies.

A novel event which is scheduled in connection with the convention is the installation of a chapter of Iota Sigma Pi composed of about 50 women chemists. This group, each member of which is following chemistry as a profession, has applied for a charter and expects to be installed at that time.

Water Pollution Conference to Be Called

An international conference of maritime nations to consider means for prevention of the pollution of navigable waters by oil burning steamers is provided in the bill recently passed by the Senate. The bill, which is now before the President for his signature, authorizes the Chief Executive to call the conference..

Manufacturing Chemists' Association Fiftieth Annual Meeting

The Manufacturing Chemists' Association of the United States celebrated its golden anniversary at its recent annual meeting held at the Whitehall Club in New York City on June 16. The salient features of the business to be conducted were the election of officers and the reading of Chairman Henry Howard's comprehensive report of the Executive Committee. This report outlined the action taken by the association on important legislative matters, such as the pending tariff and the proposed American valuation feature, the revival of the German patent treaty, the soldiers' bonus, and the bill to prohibit commercial bribery. The co-operation with such agencies as the Chemical Foundation, the Industrial Conference Board and National Foreign Trade Council was reviewed in the committee's report.

The report also contained the first public announcement of the association's negotiations with Secretary Hoover in connection with the publication of production statistics. A committee composed of President Charles L. Reese, Henry Howard and W. H. Nicholls Jr. had gone into the matter very thoroughly and concluded that the compilation of the information sought would entail considerable work and expense to the manufacturers and would more than negative any possible good coming from their publication. This was explained to Mr. Hoover and the project was abandoned.

The officers elected for the coming year are referred to under "Personal."

Chemical Exposition Back to Grand Central Palace This Year

Owing to the fact that the project to turn the Grand Central Palace, New York, into an office building has been abandoned, the Eighth National Exposition of Chemical Industries will again go back to its original home at the Palace when it is held this year during the week of Sept. 11. Last September the proposed plan of remodeling the Palace forced the Chemical Exposition to seek other quarters. The only other building, large enough and suitable for the purpose, which was available in New York was the Eighth Coast Artillery Armory.

The central location of this year's exposition, combined with the fact that the chemical industry is once again looking upward after a slump of eighteen months, is the basis for laying plans to accommodate a record attendance. Conservative estimates place the number of exhibitors who are expected to display their goods at the Exposition this year at a minimum of 450.

Personal

William P. Allen, assistant general manager of the Cellulose Products Department of E. I. du Pont de Nemours & Co., Wilmington, Del., has been appointed general manager to succeed R. R. M. Carpenter, vice-president of the company, who has been acting in this capacity during the reorganization period since last October and who will retire from the office on June 30.

Alfred Cotton Bedford, chairman of the board of directors of the Standard Oil Company of New Jersey, had conferred upon him the honorary degree of Doctor of Laws at the commencement of the University of Pittsburgh on June 14. This honor was bestowed upon Mr. Bedford in recognition of his activities in the development of the American petroleum industry and for his foresight in the encouragement of the application of scientific research.

Prof. William L. DeBaufre, chairman of the department of mechanical engineering of the University of Nebraska, is spending the summer in Washington as a member of the technical staff of the Bureau of Mines cryogenic laboratory.

C. R. DeLong, chief chemist of the U. S. Tariff Commission, has been selected to head the new chemical division of the Bureau of Foreign and Domestic Commerce, Department of Commerce. It is understood that the division will commence its work on Aug. 1.

Dr. Elbert C. Lathrop of Wilmington, Del., will shortly sever his connection with the du Pont company, where he has been manager of the standards division of the chemical department, and will join the organization of Samuel P. Sadtler & Son, Inc., as vice-president and treasurer. The arrangement will be effective on July 1.

Paul W. Litchfield, vice-president and factory manager of the Goodyear Tire & Rubber Co., Akron, Ohio, has sailed for Europe, to be absent on business for about 7 weeks. He will make a survey of current conditions in the industry in England, Scotland, Belgium, France and Germany.

Tillman D. Lynch, an engineer with the Westinghouse Electric & Manufacturing Co., has received the nomination for the presidency of the American Society for Steel Treating.

Charles L. Reese, of the du Pont Company, was elected president of the Manufacturing Chemists' Association, New York, at the annual meeting held at the Whitehall Club, June 16. C. Wilbur Miller, of the Davison Chemical Co., was elected vice-president; M. C. Whitaker, of the U. S. Industrial Alcohol Co., second vice-president; S. W. Wilder, of the Merrimac Chemical Co., treasurer, and John I. Tierney, of Washington, D. C., secretary.

Dr. J. W. Turrentine, formerly director of the experimental kelp-potash plant of the U. S. Department of Agriculture at Summerland, Calif., has obtained a furlough from the department for 6 months to act as consulting chemist for the U. S. Kelp Products Corporation, the newly organized concern which has purchased the government's plant and is now proceeding with the manufacture of kelp products.

Edward R. Weidlein, director of the Mellon Institute of Industrial Research of the University of Pittsburgh, addressed the fourth annual convention of the National Lime Association, June 16, on "The Value of Research to Industrial Associations." The convention was held in Cleveland, Ohio.

W. Woodward Williams, formerly of Pittsburgh, Pa., has been elected vice-president of the Titan Iron & Steel Co., Inc., Newark, N. J.

E. G. Zies of the Geophysical Laboratory, who expected to spend this summer in Hawaii investigating the gases from the volcanic eruptions there, has returned to Washington. Plans for the trip were materially changed because the expected lava flows from Kilauea did not materialize and the lava is now receding rapidly in the crater.

Recent appointment to industrial fellowships in the Mellon Institute of Industrial Research of the University of Pittsburgh include the following: E. R. Clark (B. A. Yale); H. E. Dietrich (A. B., Kansas); Marc Darrin (B. S. and M. S., Washington); O. B. J. Fraser (B. S., Queen's University); A. W. Harvey (B. S., Syracuse; M. S. and Ph. D., Pittsburgh); C. R. Texter (B. S., Pennsylvania State); and B. B. Wescott (B. S. and M. S., Pittsburgh).

Obituary

William G. Grieb, of Scarsdale, N. Y., one of the founders of the Ajax Rubber Co., Trenton, N. J., and former president of the company, died suddenly at his home, June 13, aged 64 years. He was actively connected with the company from its inception in 1908 until 1918, when he retired to give his services to the government during the war period. He is survived by his wife and six children.

John Craig Havemeyer, of Yonkers, N. Y., retired sugar refiner and well known throughout this industry, died at his residence, June 8, in his ninetieth year. He began in the sugar-refining business at the age of 21, and later was associated with his brother in the firm of Havemeyer & Co., with refinery at Greenpoint, L. I. He retired from active business in 1880 on account of poor health.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

The Coal and Coke Situation

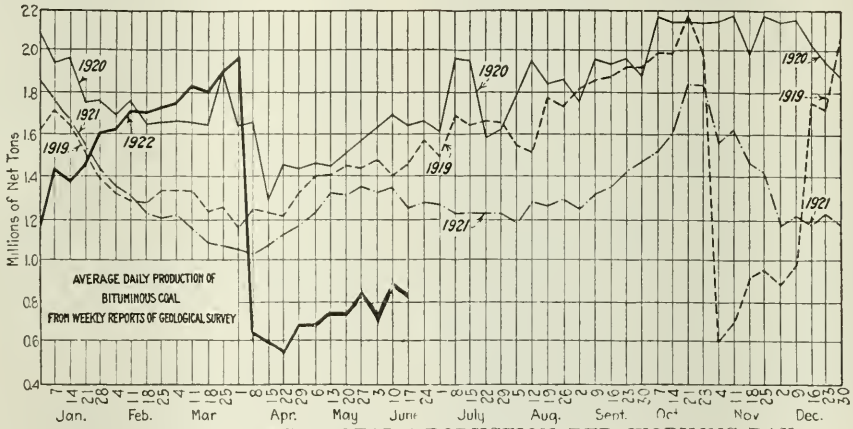
As the coal strike enters its thirteenth week, a few of the consuming industries are beginning to show a little more interest in the trend of production at the mines and in the marketing situation as it affects existing stocks. With this in mind a study has been made of the current production statistics being issued by the U. S. Geological Survey and of the market analyses appearing in the weekly issues of *Coal Age*. Barring the recent strife and uprising in the Illinois mines, it would appear that at the present time most interest is concentrated in the constantly recurring rumors of an early settlement in the bituminous coal fields. Most of these rumors are apparently founded on the belief that important interstate negotiations are likely to occur within the near future. So far, however, these have brought forth only vigorous denials from union officials in the Middle Western fields.

Some little anxiety is being shown in the Northwest on account of the fact that practically no coal has been moved to the upper lake docks and it may yet become necessary to meet an unprecedented lake demand, calling for as much as a million tons a week for 15 to 20 weeks. Aside from this situation, however, *Coal Age* is of the opinion that "the condition of the country with respect to bituminous coal on July 1 will not be far from what may be described as normal with respect not only to production and distribution, but also as to stocks."

The most potent influence as regards the market is the set of "reasonable" prices established by Secretary Hoover. These are generally regarded as a bulwark against prohibitive prices, but it is interesting to note that in most districts the coal market has been so inactive that prevailing prices are substantially less than those which Mr. Hoover holds to be adequate and satisfactory. The *Coal Age* index of spot bituminous prices stood at 274 on June 19, as compared with 284 on June 12, 255 on June 5 and slightly over 300 during the last week of May. The June 19 figure represents an average mine price of $3.31 per ton, a drop of 13c. from that of the preceding week.

The Geological Survey's estimates of the average total production of bituminous coal is shown in the accompanying chart from Jan. 1 to June 17, 1922. During the eleventh week of the strike (June 12-17) production was expected to show a decrease from the 5,078,000 net tons produced during the tenth week. Present production is compared with that of a year ago in Table I.

The anthracite situation remains unchanged; production continues to be practically nil. In the tenth week of the strike (June 3-10) the output was limited to 253 cars, all of which, so far as reported to the Geological Survey, was steam coal dredged from the rivers. In the corresponding week a year ago 1,963,000 tons was produced. Production of beehive coke in the week ended June 10 shows no improvement over the two weeks before the Memorial Day holiday. From records of cars of coke loaded at the ovens for shipment, the Geological Survey estimates the total output at 98,000 tons. In the week of May 27 production had been reported to be 97,000 tons.



ESTIMATED AVERAGE TOTAL PRODUCTION PER WORKING DAY OF BITUMINOUS COAL INCLUDING COAL COKED

Byproduct Coke Production

Production of byproduct coke continues to increase despite coal strike conditions, thus reflecting the improved business conditions in the metallurgical industry. In May over 2,500,000 tons of byproduct coke was produced.

TABLE I—ESTIMATED UNITED STATES PRODUCTION OF BITUMINOUS COAL (IN NET TONS)

	Total Bituminous, Including Coal Coked			
	1922		1921	
	Week	Calendar Year to Date	Week	Calendar Year to Date
May 27	4,889,000	162,498,000	8,166,000	158,706,000
Daily average	815,000	1,305,000	1,361,000	1,275,000
June 3	4,616,000	167,114,000	6,835,000	165,541,000
Daily average	769,000	1,280,000	1,330,000	1,277,000
June 10	5,078,000	172,192,000	8,010,000	173,551,000
Daily average	846,000	1,261,000	1,335,000	1,280,000

Thus the total coke output in May was a trifle under 3,000,000 tons. In this connection it is particularly interesting to note that the byproduct coke output of May is practically equal to the average monthly output in 1920, the year of maximum production.

In commenting on byproduct coke activities during recent months, the Survey makes the following statement:

> This increasing activity in the coke industry means an increased demand for coal. In the month of May approximately 4,326,000 tons of raw coal was consumed in coke ovens. In comparison with the monthly average for 1921, this is an increase of 38 per cent. But it is still 32 per cent short of the 1920 average.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	156.97
Last week	156.89

June, 1917	222	June, 1918	272
June, 1920	274	June, 1921	147
April, 1918 (high)	286	April, 1921 (low)	140

The minor price changes in the chemical market during the past week have had but very little effect on the index number. Slightly higher prices were noted for ammonium sulphate, barium chloride, copper sulphate and crude potassium carbonate. Refined glycerine was the only one of the index commodities for which a lower price was being quoted.

Mexican Petroleum's Spectacular Rise

During the week ended June 22 a series of spectacular advances in the stock of the Mexican Petroleum Co. brought its quotation up to 186 as compared with 133 on June 15. This phenomenal jump of 53 points in one week is generally attributed to a professional attempt to crowd out short holdings.

Officials of the New York Stock Exchange on June 23 ordered an investigation of the trading in this stock, requiring each member of the Exchange to render an account of his position in respect to this corporation's stock. The investigation failed to show evidence of any concerted attempt to corner the market, but it did result in a reaction which caused the stock to fall off about 10 points.

It is rather interesting to review the developments which might naturally have been expected to favor this stock. A week ago announcement was made of settlement with Huerta of the Mexican financial problem. This was followed by a tentative agreement over future development work in Mexico and finally by the corporation's annual report, which was made public June 22. This statement showed 1921 earnings of $12,540,684, or $26.82 per share on common stock, the best in the corporation's history.

The Trend of Prices for Laboratory Apparatus

A most interesting study of price tendencies, particularly as related to laboratory apparatus and supplies, has been prepared by S. L. Redman, of the Central Scientific Co., and is published in the June number of *The Chemical Bulletin*. By taking as concrete illustrations eight staple items of laboratory supplies such as a No. 0 evaporating dish, a 250-c.c. Griffin beaker, a 400-c.c. Florence flask, etc., the author was able to show that the average retail prices for these items in 1919 reached a peak of 50 per cent above the pre-war year of 1913 and that the present level is about 38 per cent above the pre-war. This is to be compared with Dun's index of prices for all commodities, which had a 1919 peak 95 per cent above the 1913 level and is at present about 33 per cent above pre-war.

The prices for these items in 1913, 1919 and May, 1922, have been compared with the prices for foreign-made supplies in the following table:

Item	1913	1919	May, 1922 — American Made	May, 1922 — German Made
Evaporating dish, No. 0	$0.19	$0.24	$0.24	$0.35
Griffin beaker, 250 c.c.	.22	.25	.25	.25
Florence flask, 400 c. c.	.24	.27	.27	.32
Cylindrical graduate, 100 c.c.	.50	.63	.60	.89
Thermometer, 110° C.	.80	1.20	1.10	1.10
Bunsen funnel, 3 in.	.18	.43	.35	.38
Soxhlet extraction apparatus, 100 c.c.	2.70	3.85	3.80	4.00
Bunsen burner	.22	.45	.35	2.15

In order to make fair comparisons between the prices of foreign-made and domestic-made apparatus corresponding grades were selected from prominent American and foreign brands. Thus for this purpose, the following brands were assumed to be of equivalent grade: Royal Berlin and Coors porcelain dishes, Jena and Pyrex beakers and flasks, Siebert & Kuhn and Taylor thermometers, and Greiner & Friedrichs and Kimble funnels.

In outlining the present situation, as well as the probable future trend of prices, Mr. Redman summarized his remarks as follows:

"There has been a continued downward trend in the price of laboratory supplies during the past 18 moths, except in those staple lines of glassware and porcelain the prices of which remained stationary during the war and post-war period of rising costs. Prices will probably continue to recede gradually throughout a period of years until the pre-war level is reached. Special instruments, whose cost of development was very high, were introduced at rather high prices and, as the process of manufacture has been perfected, generous price reductions have been made. No immediate relief is to be expected from the importation of German goods, since the difficulties experienced by German manufacturers with raw materials purchased with a depreciated currency, with restricted fuel supplies and labor troubles combine to make prices higher than those of the corresponding grade of American-made materials."

The New York Market

New York, June 26, 1922.

The chemical market during the past week showed signs of irregularity, with the demand in most instances for specialties. One of the outstanding features in the week's trading was the firmer tone displayed in prussiates. An improved demand was also noted for sulphate of ammonia from the Far East and for caustic soda from several foreign countries. Prussiate of soda has shown a strong tendency to recover from its recent slump and prices gained 1c. per lb. during the latter part of the week. Copper sulphate continued along the same steady lines, with spot stocks exceedingly light and prices firmly maintained. Yellow and red prussiate of potash are quoted higher because of the pronounced scarcity. Tartaric and citric acids are moving as usual at this season and prices are quoted fractionally higher on both items.

General and Special Chemicals

Acetic Acid—Commercial 28 per cent is being quoted at 2¼@2½c. per lb. by producers, with the demand only moderate. Glacial is held at 8½@9c. per lb. by second hands. Competition in the higher grade is much keener for passing business.

Ammonium Sulphate—Export inquiry has contributed to the better demand and prices among leading dealers were held around $3.30@$3.40 per 100 lb., f.a.s. New York.

Carbonate of Potash—The 80-85 per cent calcined, on spot, is reported firmer and prices were quoted on the basis of 5@5¼c. per lb. by prominent importers. Business in this product has been rather quiet during the past few weeks.

Caustic Soda—Quotations for 16 per cent solid, standard branch, are named around $3.80@$3.85 per 100 lb. f.a.s. New York. Export inquiries are showing increased proportions and leading factors are of the opinion that business will show a marked increase in volume in the very near future. Domestic resale is quoted at $3.75 per 100 lb. Contracts remain quotably unchanged.

Chlorate of Potash—Imported material has been offered rather freely at 6¼@6¾c. per lb. Domestic makers continue to name 8c. per lb. f.o.b. works and are holding firm at this level.

Chloroform—Producers have reduced prices on U.S.P. goods in quantities of 50 lb. to 25c. per lb., drums extra. Small lot containers are quoted at 28½@32c. per lb., depending upon size.

Citric Acid—The general condition of this market has shown a noticeable improvement with the coming of the hot weather. Some large sales were reported at 45c. per lb. Lesser quantities were held around 45½@46c. per lb.

Prussiate of Potash—Several sales of yellow prussiate were recorded at 32½c. per lb. Goods due to arrive from abroad were offered at 31@31½c. per lb. The market displayed a much firmer note and demand was quite active. The red variety was in exceedingly light supply at 90@95c. per lb.

Prussiate of Soda—Prices during the week have shown a net advance, and 22c. per lb. was named as the low figure. Several heavy arrivals of imported material were reported during the week, but these apparently had no effect on quotations.

Tartaric Acid—Crystals are quoted at 29½c. per lb. and powdered at 30c. Domestic makers continue to quote 30c. per lb.

Zinc Sulphate—Producers report a regular demand from the paint trade and quote carlots at 2¾c. per lb. Smaller lots are named around 3@3½c. per lb., depending upon quantity.

Vegetable Oils

Cottonseed Oil—Trading in the various grades was limited and prices were somewhat irregular.

Linseed Oil—During the early part of the week prices were rather weak and sales were reported down to 80c. per gal. The latter part, however, brought the market to a firmer position and leading crushers advanced their prices to 82c. per gal. The general inquiry was quiet, with the larger consumers content to watch for further developments. English oil displayed a firmer tone and quotations were heard around 76½c. per gal., duty paid.

The Iron and Steel Market

PITTSBURGH, June 23, 1922.

The steel market has grown still quieter in the past week as to the total tonnage turnover, while prices in a general way have shown a stiffening tendency.

The decrease in the tonnage turnover represents a continuance of the trend that has been seen since April, which was the high month for sales, and may perhaps be attributable solely or chiefly to the near approach of the midsummer season and the resulting dull market for steel.

It is no new experience for the steel market to appear to grow firmer as it becomes less active. The point is that when there is a heavy turnover the sales are chiefly for extended delivery, at basis prices. When forward buying decreases in volume the buying for early delivery is forced into prominence. The prompt prices contain delivery premiums, but the appearance is that of higher prices being paid on an average.

STEEL PRICES

The American Sheet & Tin Plate Co. has opened its sheet order books for August and September at former prices, its opening on June 2 having been for July only. The prices are those that became effective early in April, there being an advance of $3 a ton at the time, and are as follows: Blue annealed sheets, 2.40c.; black sheets, 3.15c.; galvanized sheets, 4.15c.; automobile sheets, 4.50c.

The incident is an important illustration of what has come to be recognized as the Steel Corporation's policy to hold its prices substantially at the present level, since advances occurred earlier in the year in the lines that were selling at unreasonably low levels on the basis of production cost. In the majority of lines, including sheets, so many independents have been quoting advanced prices that it would have been entirely feasible for the corporation to establish higher levels.

The finished steel market is quotable as follows: Bars, shapes and plates, 1.60@1.70c.; hoops and bands, 2.40@2.50c.; wire nails, $2.40@$2.50; blue annealed sheets, 2.40@2.50c.; black sheets, 3.15@3.30c.; galvanized sheets, 4.15@4.30c.; automobile sheets, 4.50@4.75c.; tin plate, $4.75; standard steel pipe, 71 per cent basing discount.

Production of steel ingots continues at a rate of about 39,000,000 tons a year, against rates of about 35,000,000 tons on April 1 and 20,000,000 tons in December. On the whole there has been a slight trend toward an increase in the past week or two. The Carnegie Steel Co. has blown in a third furnace at the Farrell plant, giving it thirty-eight furnaces in operation against thirty-four on April 1, while its ingot production is at fully 77 per cent, against an average of not over 70 per cent in the second half of March and during April.

The strike at the union coal mines shows no visible change. In the Connellsville region the return of sympathetic strikers to work in the past 10 days has been sufficient to make a decided increase in coal production, while until recently the gains in the number of workers were scarcely more than enough to show positively that the strikes were not gaining ground. Doubtless on the whole the steel industry has drawn largely upon its stocks of coal, but it certainly exhibits no signs of being forced to reduce its operations in the near future.

ORE, IRON AND COKE MARKETS

Open market transactions in Lake Superior iron ore have been light since the season opened a fortnight ago, the chief business being between producers and consumers having more or less joint ownership. Producers expect to sell little if any ore to Eastern furnaces for the season, because at $5.05 f.o.b. Lake Erie dock for Mesabi non-bessemer ore the cost to Eastern furnaces is computed at $7.07 per ton, or 13.728c. per unit, while foreign ore is quoted at 10.5c. per unit delivered and could probably be bought for less.

The pig iron market in Pittsburgh and the valleys has been very quiet in the past week. Consumers are showing greater power to stay out of the market than was expected. The iron foundries are far from busy, while the steel works that do not produce iron have not been selling their product far ahead. Buyers expect a downward readjustment in pig iron prices when coke becomes less scarce. The market is largely nominal at former quotations, $25 for bessemer and basic and $24@$25 for foundry, f.o.b. valley furnaces.

Not enough Connellsville furnace coke is moving to make a regular market. Miscellaneous consumers, other than blast furnaces, are occasionally forced to buy, paying, say, $7.50 for standard grade, while high-sulphur coke is obtainable at $7. Foundry coke is selling in a limited way at $8@$8.50.

The St. Louis Market

ST. LOUIS, Mo., June 22, 1922.

We wish to confirm our previous reports that there is a continual steady increase in the amount of business being transacted in the industrial chemical market in this locality, and the summer lull which is usually expected at this time has not as yet appeared. We do not believe there will be any great slackening off of business during the summer period for reason that buying is still being done on a conservative basis with a quick turnover in mind, but it is true that buyers are more confident today than a year ago, and are more liberal in placing their requirements. While some few chemicals on the list, particularly the alkalis, showed a decided weakness the majority were very firm and in many instances were stiffened.

ALKALIS

Caustic soda has shown a slight weakening since our last report and regular prices are now being shaded on large-sized orders. Carload business is increasing somewhat and it is in this class of buying where price shading is most evident. *Soda ash* is being offered as low as $2.25 in barrels in lots of 5 to 10 bbl. In the main, however, the nominal price of $2.40 in 5-bbl. lots with a 20c. differential is being maintained. *Sodium bicarbonate* is very unsteady and, as put by one jobber, is being sold for whatever it will bring. $2.25 in 5-bbl. lots seems to be about the average price. *Sal soda* is apparently somewhat of a drug on the market. As low as $1.65 cwt. in barrels has been reported.

GENERAL AND SPECIAL CHEMICALS

The heavy commercial *mineral acids* are showing a decided improvement with prices stiffening in some directions. The demand from the fertilizer trade is very good while that from steel mills has fallen off. *Carbolic* is in good demand with prices firm. Spot stocks of *citric acid* are still very scarce and the demand this season is no greater than last, and for the present we do not believe there will be any advance in price. *Phosphoric acid* is moving in a good way with fairly large sales reported. *White arsenic*, powdered, remains the same in price at 7½c. per lb., f.o.b. St. Louis, but the market has stiffened considerably with a very good demand coming from the insecticide manufacturers. *Carbon bisulphide* has been moving very briskly since our last report and the demand should continue, as we are now in a season when this article will be used very extensively as an insecticide. *Carbon tetrachloride* is holding its own both in price and demand. *Chloroform* is very weak and manufacturers have found it necessary to make a further reduction of 5c. per lb. *Glycerine* has finally responded to prophecies and has declined to 12½c. per lb. in drums with the usual differential on cans. Contracts with protection are being offered at 15c. There has been an unexpected demand for *lithium carbonate* for export and some good-sized orders have been reported. *Potassium cyanide* stocks are very limited and the demand has been from usual channels. *Sodium fluoride* is not moving as freely as should be expected. *Zinc spelter* has stiffened a few points and is now being quoted at $5.35@$5.40 per 100 lb. in carload lots, f.o.b. St. Louis, while the *sulphate* remains the same in price as well as demand.

VEGETABLE OILS AND NAVAL STORES

Castor oil remains firm at 12¾c. in 200-gal. lots with an advance of 1c. for less quantities. Demand is good with a large volume movement. *Linseed oil* has shown some weakness with a decline from $1.07 to 97c. basis raw oil. With the prospective tariff pending this price decline was hardly expected. *Turpentine* is holding its own very nicely having maintained its position around the dollar mark consistently for the last month.

Sulphuric, 60 deg., drums	ton	12 00 – 14 00	..... – .....
Sulphuric, 66 deg., tank cars	ton	15 00 – 16 00	..... – .....
Sulphuric, 66 deg., drums	ton	19 00 – 20 00	20.50 – 21 00
Sulphuric, 66 deg., carboys	ton	..... –	..... – .....
Sulphuric, fuming, 20 per cent (oleum) tank cars	ton	19 00 – 20.00	..... – .....
Sulphuric, fuming, 20 per cent (oleum) drums	ton	22 00 – 22 50	23.00 – 24.00
Sulphuric, fuming, 20 per cent (oleum) carboys	ton	31 00 – 32 00	33.00 – 34 00
Tannic, U. S. P.	lb.	..... –	.60 – .75
Tannic (tech.)	lb.	40 – .45	.46 – .50
Tartaric, imported crystals	lb.	..... –	.29 – .29½
Tartaric acid, imported, powdered	lb.	..... –	.29½ – .30
Tartaric acid, domestic	lb.	..... –	..... – .30
Tungstic, per lb. of WO	lb.	..... –	1 00 – 1 10
Alcohol, ethyl (Cologne spirit)	gal.	..... –	4.75 – 4 95
Alcohol, methyl (see methanol)		..... –	..... – .....
Alcohol, denatured, 188 proof No. 1	gal.	..... –	.26 – .39
Alcohol, denatured, 188 proof No. 5	gal.	..... –	.26 – .30
Alum, ammonia, lump	lb.	.03½ – .03¾	.04 – .04½
Alum, potash, lump	lb.	.03¾ – .04	.04½ – .05
Alum, chrome lump	lb.	05¼ – 05¾	06 – 06½
Aluminum sulphate, commercial	100 lb.	1 50 – 1.65	1.70 – 2 25
Aluminum sulphate, iron free	lb.	02½ – 02¾	.03 – .03¼
Aqua ammonia, 26 deg., drums (750 lb.)	lb.	.06¾ – 07¼	.07½ – .08
Ammonia, anhydrous, cyl. (100-150 lb.)	lb.	.30 – .30½	.30½ – .31
Ammonium carbonate, powder	lb.	.07 – .07½	.07¾ – .08
Ammonium nitrate	lb.	.06 – .06½	.06¾ – 07½
Amylacetate tech	gal.	..... –	2 00 – 2 25
Arsenic, white, powdered	lb.	.07½ – 07¼	.07¾ – 08
Arsenic, red, powdered	lb.	.12 – .12¼	.12¾ – .13
Barium carbonate	lb.	.03 – .04	.04¾ – .05
Barium chloride	ton	95.00 –100 00	105.00 –110.00
Barium dioxide (peroxide)	lb.	.20 – .21	.21½ – .22
Barium nitrate	lb.	.07 – 07¼	.07½ – .08
Barium sulphate (precip.) (blanc fixe)	lb.	.04 – .04¼	.04¾ – .04¾
Blanc fixe, dry	lb.	.04 – .04¾	..... – .....
Blanc fixe, pulp	ton	45 00 – 55 00	..... – .....
Bleaching powder	100 lb.	1 60 – 1.75	1 85 – 2.50
Blue vitriol (see copper sulphate)		..... –	..... – .....
Borax	lb.	.05½ – .05¾	.06 – .06¾
Brimstone (see sulphur, roll)		..... –	..... – .....
Bromine	lb.	.27 – .28	.28½ – .35
Calcium acetate	100 lbs.	1.75 – 2 00	..... – .....
Calcium carbide	lb.	.04½ – .04¾	.05 – 05½
Calcium chloride, fused, lump	ton	24.00 – 24 50	24 75 – 27 00
Calcium chloride, granulated	lb.	.01½ – .01¾	.02 – 02¼
Calcium peroxide	lb.	..... –	1 40 – 1 50
Calcium phosphate, tribasic	lb.	..... –	15 – 16
Camphor	lb.	..... –	.79 – 83
Carbon bisulphide	lb.	.06½ – .06¾	07 – 07½
Carbon tetrachloride, drums	lb.	.09½ – .10	10½ – .12
Carbonyl chloride, (phosgene)	lb.	..... –	.60 – .75
Caustic potash (see potassium hydroxide)		..... –	..... – .....
Caustic soda (see sodium hydroxide)		..... –	..... – .....
Chalk, precip.—domestic, light	lb.	.04¼ – .04½	..... – .....
Chalk, precip.—domestic, heavy	lb.	.03½ – .03¾	..... – .....
Chalk, precip.—imported, light	lb.	.04½ – .05	..... – .....
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.05 – .05½	.05¾ – .06
Chloroform	lb.	..... –	.25 – 32
Cobalt oxide	lb.	..... –	2 00 – 2 10
Copperas	ton	20.00 – 22 00	23.00 – 30 00
Copper carbonate, green precipitate	lb.	.19 – .20	.20½ – .21
Copper cyanide	lb.	..... –	.58 – .60
Copper sulphate, crystals	100 lb.	6.25 – 6 40	6 45 – 6 65
Cream of tartar	lb.	..... –	.23½ – .25
Epsom salt (see magnesium sulphate)		..... –	..... – .....
Ethyl acetate com. 85%	gal.	..... –	.60 – .65
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.	..... –	.90 – .95
Formaldehyde, 40 per cent	lb.	.08½ – .08½	.08¾ – .09
Fullers earth, f.o.b. mines	net ton	16 00 – 17 00	..... – .....
Fullers earth—imported powdered—net	ton	30 00 – 32 00	..... – .....
Fusel oil, ref	gal.	..... –	2 25 – 2 65
Fusel oil, crude	gal.	..... –	1 40 – 1 50
Glauber's salt (see sodium sulphate)		..... –	..... – .....
Glycerine, c. p. drums extra	lb.	..... –	.14½ – .14¾
Iodine, resublimed	lb.	..... –	4 20 – 4 25
Iron oxide, red	lb.	..... –	.12 – .18
Lead acetate	lb.	..... –	.09¾ – .11½
Lead arsenate, powd	lb.	.13 – .13½	.13¾ – .14¼
Lead nitrate	lb.	..... –	.15 – .20
Litharge	lb.	.07¾ – .08	.08¼ – .09
Magnesium carbonate, technical	lb.	.08½ – .08¾	.09 – .09½
Magnesium sulphate, U. S. P.	100 lb.	2.50 – 2.60	2.65 – 2 85
Magnesium sulphate, technical	100 lb.	..... –	1.00 – 1 80
Methanol, 95%	gal.	..... –	.57 – .58
Methanol, 97%	gal.	..... –	.59 – .60
Nickel salt, double	lb.	..... –	.11 – .11½
Nickel salt, single	lb.	..... –	.10 – .10¼
Phogene (see carbonyl chloride)		..... –	..... – .....
Phosphorus, red	lb.	..... –	.40 – .45
Phosphorus, yellow	lb.	..... –	.30 – .35
Potassium bichromate	lb.	09¼ – 10	10½ – 10
Potassium bromide, granular	lb.	..... –	.17 – 25
Potassium carbonate, U. S. P.	lb.	.12 – 12½	.13 – 16
Potassium carbonate, 80-85%	lb.	.05 – .05¼	.05½ – 06
Potassium chlorate powdered and crystals	lb.	.06½ – .07	.07½ – 08
Potassium cyanide	lb.	..... –	.45 – 50
Potassium hydroxide (caustic potash)	100 lb.	5.75 – 6 00	6 25 – 6 50
Potassium iodide	lb.	..... –	3.20 – 3.30
Potassium nitrate	lb.	.06¼ – .06½	.07 – .08
Potassium permanganate	lb.	14 – .14½	.14¼ – .15½
Potassium prussiate, red	lb.	..... –	.90 – .95
Potassium prussiate, yellow	lb.	32½ – .33	.33½ – .34
Rochelle salts (see sodium potas tartrate)		..... –	..... – .....
Salammoniac, white, granular	lb.	06½ – .07	.07½ – .08
Salammoniac, gray, granular	lb.	07¼ – .08	.08¼ – .08½
Salsoda	100 lb.	1 20 – 1 40	1.45 – 1 60
Salt cake (bulk)	ton	20.00 –25.00	..... – .....
Soda ash, light, 58 per cent flat, bags, contract	100 lb.	1 65 – 1.70	2.00 – 2.25
Soda ash, light, 58 per cent flat, bags, resale	100 lb.	1 80 – 1 90	1.95 – 2 40
Soda ash, dense, in bags, resale	100 lb.	1 90 – 1.95	2.00 – 2.50
Sodium acetate	lb.	.05½ – .06	.06½ – 06¾
Sodium bicarbonate	100 lb.	1.75 – 1.85	1.90 – 2 00
Sodium bichromate	lb.	.07½ – .07¾	.07½ – 08
Sodium bisulphate (nitre cake)	ton	4.50 – 4.60	4.65 – 5 50
Sodium bisulphite powdered, U.S.P.	lb.	.04¼ – .04½	.04½ – .05¼
Sodium chlorate	lb.	.06¼ – .06½	.07 – .07½
Sodium chloride	long ton	12 00 – 13 00	..... – .....
Sodium cyanide	lb.	.22 – .23	.23½ – .25
Sodium fluoride	lb.	.10 – .10½	.10½ – .11
Sodium hydroxide (caustic soda) solid, 76 per cent flat, drums, contract	100 lb.	3 35 – 3.50	3.80 – 4 00
Sodium hydroxide (caustic soda) solid, 76% flat, drums, resale	100 lb.	3.80 – 3.85	3.90 – 4.20
Sodium hydroxide (caustic soda), ground and flake, contracts	100 lb.	3.85 – 4.00	4.30 – 4.50
Sodium hydroxide (caustic soda) ground and flake, resale	100 lb.	4 00 – 4 15	4.40 – 4 60
Sodium hyposulphite	lb.	.03 – .03½	.03½ – .04
Sodium nitrite	lb.	.08¼ – .08¾	.09 – .09½
Sodium peroxide, powdered	lb.	.28 – .30	.31 – .35
Sodium phosphate, dibasic	lb.	.03½ – .04	.04¼ – .04½
Sodium potassium tartrate (Rochelle salts)	lb.	..... –	.18 – .21
Sodium prussiate, yellow	lb.	.22 – .22½	.22½ – .23
Sodium silicate, (40 deg. in drums)	100 lb.	.80 – 1.00	1.05 – 1.25
Sodium silicate, (60 deg. in drums)	100 lb.	2.25 – 2.40	2.45 – 2.75
Sodium sulphate, crystals (glaubers salt)	100 lbs.	.95 – 1.05	1.15 – 1.50
Sodium sulphide, fused, 60-62 per cent (tone.)	lb.	.04¼ – .04½	.04½ – .05
Sodium sulphite, crystals	lb.	.03¼ – .03⅜	.03⅜ – .04¼
Strontium nitrate, powdered	lb.	.09¾ – .10	.10¼ – .12
Sulphur chloride, yellow	lb.	.04½ – .05	.05½ – .06
Sulphur, crude	ton	18 00 –20.00	..... – .....
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.	..... –	2.25 – 3.10
Sulphur, roll (brimstone)	100 lb.	2.00 – 2.15	2.20 – 2.70
Talc—imported	ton	30 00 –40 00	..... – .....
Talc—domestic powdered	ton	18 00 –25.00	..... – .....
Tin bichloride	lb.	.09 – .09½	.09½ – .10
Tin oxide	lb.	..... –	.35 – .37
Zinc carbonate	lb.	.14 – .14½	.14½ – 15½
Zinc chloride, gran	lb.	.06 – .06½	.06½ – .07
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08¼ – .08½
Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$1.00 — $1 05
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.30 — .31
Aniline oil, drums extra	lb.	.14 — .16
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1 30
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.80 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.50 — .55
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.50 — .55
Beta-naphthol, tech	lb.	.23 — .26
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.56 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.51 — .58
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.65 — .70
Dimethylaniline	lb.	.36 — .38
Dinitrobenzene	lb.	.22 — 25
Dinitroclorbenzene	lb.	.22 — .24
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.33 — .35
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.24 — .26
Diphenylamine	lb.	.59 — .65
H-acid	lb.	.85 — .95
Meta-phenylenediamine	lb.	.95 — 1.00
Monochlorbenzene	lb.	.09 — .11
Monoethylaniline	lb.	1.00 — 1.20
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.08 — .08
Naphthionate of soda	lb.	.58 — .65
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17
N-W acid	lb.	1 15 — 1 30
Ortho-amidophenol	lb.	2.40 — 2.50
Ortho-dichlor-benzene	lb.	2.15 — .20
Ortho-nitro-phenol	lb.	.70 — .75

Ortho-nitro-toluene	lb.	$0 10 —	$0.13
Ortho-toluidine	lb.	.14 —	.18
Para-amidophenol, base	lb.	1.25 —	1.30
Para-amidophenol, HCl	lb.	1.30 —	1.35
Para-dichlorbenzene	lb.	.17 —	.20
Paranitroaniline	lb.	.72 —	.75
Para-nitrotoluene	lb.	.55 —	.65
Para-phenylenediamine	lb.	1.55 —	1.60
Para-toluidine	lb.	.90 —	1.00
Phthalic anhydride	lb.	.35 —	.38
Phenol, U. S. P., drums	lb.	.14 —	15
Pyridine	gal.	1.75 —	2.75
Resorcinol, technical	lb.	1.30 —	1 35
Resorcinol, pure	lb.	1.75 —	1.80
R-salt	lb.	.60 —	.70
Salicylic acid, tech., in bbls	lb.	.25 —	.25½
Salicylic acid, U. S. P	lb.	.26 —	.26½
Solvent naphtha, water-white, in drums, 100 gal	gal.	.27 —	.32
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.14 —	.18
Sulphanilic acid, crude	lb.	.24 —	.26
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	.28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	.33 —	.35
Xylene, commercial, in tank cars	gal.	.30 —	....

Waxes

Candellila, wax	lb.	.40 —	.42

All Other Prices Remain Unchanged

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl	280 lb.	$5.60 —	$6.00
Rosin E-I	280 lb.	6.05 —	6.35
Rosin K-N	280 lb.	6.65 —	6.90
Rosin W. G.-W. W	280 lb.	7.70 —	8.35
Wood rosin, bbl	280 lb.	6.25 —	....
Spirits of turpentine	gal.	1.25 —	1.27
Wood turpentine, steam dist	gal.	.85 —	....
Wood turpentine, dest. dist	gal.	.70 —	.70
Pine tar pitch, bbl	200 lb.	..... —	6.00
Tar, kiln burned, bbl. (500 lb.)	bbl.	..... —	9.50
Retort tar, bbl	500 lb.	—	9.00
Rosin oil, first run	gal.	.36 —	....
Rosin oil, second run	gal.	.38 —	....
Rosin oil, third run	gal.	.46 —	....
Pine oil, steam dist., sp.gr., 0.930-0.940	gal.		1.00
Pine oil, pure, dest. dist	gal.		.95
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.		.46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla	gal.		.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.		.75
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.		.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.		.25
Pinewood creosote, ref	gal.		.52

Fertilizers

Ammonium sulphate, f.a.s., N.Y	100 lb.	3.30 —	3.40
Blood, dried, f.o.b., N. Y	unit	3.55 —	3.65
Bone, 3 and 50, ground, raw	ton	27.00 —	28.00
Fish scrap, dom., dried, f.o.b. works	unit	3.10 —	3.20
Nitrate of soda	100 lb.	2.55 —	2.60
Tankage, high grade, f.o.b. Chicago	unit	3.00 —	3.10
Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	3.50 —	3.75
Tennessee, 78-80%	ton	7.00 —	7.50
Potassium muriate, 80%	ton	33.00 —	33.50
Potassium sulphate	unit	1.00 —	....

Crude Rubber

Para—Upriver fine	lb.	$0.18 —	.18½
Upriver coarse	lb.	.12½ —	.12¾
Upriver caucho ball	lb.	.13¾ —	.14
Plantation—First latex crepe	lb.	.15⅛ —	.15¼
Ribbed smoked sheets	lb.	.15⅛ —	.15¼
Brown crepe, thin, clean	lb.	.13¾ —	....
Amber crepe No. 1	lb.	.14½ —	....

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.11 —	$0.11½
Castor oil, AA, in bbls	lb.	.12 —	.12¼
China wood oil, in bbls	lb.	.13¾ —	.14
Cocoanut oil, Ceylon grade, in bbls	lb.	.08½ —	.08¾
Coconut oil, Cochin grade, in bbls	lb.	.09¼ —	.09½
Corn oil, crude, in bbls	lb.	.11¼ —	.11½
Cottonseed oil, crude (f. o. b. mill)	lb.	$0.10 —	$0.10
Cottonseed oil, summer yellow	lb.	.11¾ —	.12
Cottonseed oil, winter yellow	lb.	.12½ —	.13
Linseed oil, raw, car lots (domestic)	gal.	.82 —	.83
Linseed oil, raw, tank cars (domestic)	gal.	.78 —	.79
Linseed oil, boiled, in 5-bbl lots (domestic)	gal.	.87 —	.88
Olive oil, denatured	gal.	1.15 —	1.17
Palm, Lagos	lb.	.07½ —	.07
Palm, Niger	lb.	.06½ —	.06
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.09¼ —	.10
Peanut oil, refined, in bbls	lb.	.12½ —	.12¾
Rapeseed oil, refined in bbls	gal.	.84 —	.85
Rapeseed oil, blown, in bbls	gal.	.88 —	.89
Soya bean oil (Manchurian), in bbls. N. Y	lb.	.12½ —	....
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.10½ —	....

FISH

Light pressed menhaden	gal.	$0.51 —	....
Yellow bleached menhaden	gal.	.53 —	.54
White bleached menhaden	gal.	.55 —	.56
Blown menhaden	gal.	.61 —	....
Whale Oil, No. 1, crude, tanks, coast	gal.	.45 —	.48

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

LITTLE ROCK—The Arkansas Foundry Co., manufacturer of gray iron castings, has awarded a contract to the Hermann McCain Construction Co., Little Rock, for the erection of a new 1-story foundry to cost about $20,000. It will be equipped for a capacity of about 20 tons per day.

California

COLTON—The Southern California Gas Co. will make extensions and improvements in its local artificial gas plant to cost about $150,000, increasing the capacity by about 50 per cent. The work will include the installation of two new generators, boilers, purifiers, and auxiliary equipment. H. C. McAllister is division manager.

PITTSBURG—The Columbia Steel Co., 503 Market St., San Francisco, has preliminary plans under way for the erection of a large addition to its local plant, estimated to cost in excess of $1,000,000. W. E. Creed is president.

ANAHEIM—A new 1-story foundry will be erected by the Oil Tool Service Mfg. Co. at Santa Ana and Atchison Sts. M. N. Putnam heads the company.

JOHANNESBURG—The Standard Oil Co. of California, San Francisco, will commence the immediate erection of a new oil-distributing plant on local site, to be used in connection with its operations in the Bakersfield district.

SAN DIEGO—The San Diego Consolidated Gas Co. will construct a new artificial gas container and plant at 12th and K Sts., estimated to cost about $350,000.

Connecticut

NORWALK—The Mecker's Iron Foundry Corp. is reported to be planning for the early rebuilding of the portion of its foundry destroyed by fire, June 15, with loss approximating $60,000.

Florida

JACKSONVILLE—The Federal Phosphoric Co., Birmingham, Ala., is said to have tentative plans under consideration for the establishment of a new fertilizer manufacturing plant on local site. T. L. Long is in charge.

Georgia

ATLANTA—Fire, June 10, destroyed a portion of the plant of the Southern Chemical Products Co., 600 Marietta St., with loss estimated at about $15,000.

GREENSBORO—The Southern Cotton Oil Co. is reported to be planning for enlargements in its local plant.

Illinois

ROCK ISLAND—The Illinois Oil Co., 215 Safety Bldg., has awarded a contract to the R. H. Lorenz Co., Moline, Ill., for the erection of a 3-story plant, 40x150 ft., at 4th Ave and 24th St., estimated to cost about $135,000, including equipment. Frank J. Welsh is president.

Indiana

ANDERSON—The Beaver Products Co., Buffalo, N. Y., a subsidiary of the Beaver Board Companies, Inc., recently organized, has acquired the local plant of the Vulcanite Co., used for the manufacture of paper composition roofing, etc. Operations will be continued as heretofore, and it is said that a number of improvements will be made.

Kansas

CANEY—The C. F. Lutes Window Glass Co. has preliminary plans under consideration for the rebuilding of the portion of its plant destroyed by fire, June 8, with loss estimated at close to $200,000, including equipment. C. F. Lutes is president and manager.

Louisiana

SWARTZ—The Ebon Carbon Co. has plans in progress for the removal of its plant, now located at Cedar Grove, La., to Swartz. The Western Carbon Co., Cedar Grove, is also arranging for the removal of its plant to the same new location. It is expected to increase the output at the new works.

THIBODAUX—The City Council is considering the installation of a new water purification plant at the municipal waterworks.

MONROE—The Southwest Pulp & Paper Co., Joseph G. Mayo, president, 206 Broadway, Norwich, Conn., has perfected its organization under Delaware laws with a capital of $2,500,000, and will soon commence the erection of its proposed new plant on the Monroe-Columbia Highway, estimated to cost approximately $250,000, including equipment. The plant will have an initial output of about 100 tons per day.

NATCHITOCHES—The Natchitoches Cotton Oil Co. and the Planters' Cotton Oil Mill, the latter with plant at Grand Ecore, La., have been consolidated into a new company, under the first-noted name. The Grand Ecore oil mill will be removed to the local site of the Natchitoches company, where a new plant will be constructed, replacing a mill destroyed by fire a number of months ago. New machinery will be installed for considerable increase in capacity. J. H. Williams is president; and W. P. Haynes, general manager.

Maryland

BALTIMORE—The City Architectural Commission has authorized the preparation of plans for the construction of a new filtration plant at Montebello, to cost close to $1,000,000, with equipment. It will have a capacity of about 90,000,000 gal. William W. Emmart, 1101 Union Trust Bldg., Baltimore, is architect.

Massachusetts

BOSTON—K. J. Quinn & Co., Inc., 481 Chelsea St., manufacturer of polishes, etc., has awarded a contract to L. D. Willcut & Sons, 146 Summer St., for the construction of a new 2-story plant, 30x60 ft., estimated to cost about $25,000.

Missouri

COLUMBIA—The City Council is arranging for the purchase of the plant of the Columbia Gas Co., for operation as municipal property. A bond issue of $100,000 will be voted to provide for the acquisition, and proposed additions and improvements.

New Jersey

GARFIELD—The Heyden Chemical Co. of America, Inc., 135 William St., New York, N. Y., has awarded a contract to the Gabler Construction Co., 402 Hudson St., New York, for the construction of a new 5-story plant at Garfield, to cost about $90,000.

TRENTON—The New Jersey Porcelain Co., Pennsylvania Ave., has filed plans for the construction of a new 1-story plant.

MAURER—The United Lead Co., 111 Broadway, New York, N. Y., has preliminary plans under way for the rebuilding of the portion of its plant at Maurer, near Perth Amboy, destroyed by fire on May 16, with loss reported in excess of $1,000,000.

HOBOKEN—The Fisher-Sweeny Bronze Co., 1301 Grand St., will take bids at once for the construction of a new 1- and 2-story foundry, to replace the portion of its works recently destroyed by fire. It will cost close to $80,000. Lockwood, Greene & Co., 101 Park Ave., New York, is architect.

New York

RETSOF—The Retsof Mining Co. has awarded a contract to the John W. Cowper Co., Fidelity Bldg., Buffalo, N. Y., for the construction of its proposed new 1- and 2-story plant for salt mining and refining, estimated to cost in excess of $1,000,000, including machinery. T. F. Courthope is engineer, for the company.

NEW YORK—The Super-Saftee Ink Corp., 219 West 27th St., manufacturer of special non-corrosive inks, chemically treated, is disposing of a preferred stock issue totalling about $250,000, the proceeds to be used for general expansion. Preliminary plans are under way for the establishment of branch plants at Boston, Chicago, St. Louis, Mo., Atlanta, Ga., and other cities.

NORTH TONAWANDA—The Board of Public Works will commence the immediate construction of a new filtration plant on Tonawanda Island for the municipal water works, to cost about $250,000, including equipment. It is proposed to have the plant ready for service early in the coming year.

Ohio

CLEVELAND—The Diamond Glass Co., 1447 West 25th St., is said to be planning for the immediate rebuilding of the portion of its local plant destroyed by fire, June 5, with loss approximating $300,000, including machinery.

CLEVELAND—The Crucible Steel Castings Co., Champlain Ave. and Canal Road, has plans under way for the construction of a new 1-story foundry on Almira Ave. near West 82nd St., estimated to cost close to $100,000, with equipment. The George S. Rider Co., 612 Century Bldg., is engineer.

DENNISON—The local plant of the Dennison Fireclay & Brick Co. has been acquired by John Scott and Walter Moore, Uhrichsville, O., from C. A. Albaugh, trustee in bankruptcy. The new owners will reorganize the company and place the plant in operation at once. A number of extensions and improvements will be made.

Oregon

GRESHAM—The Pacific Malleable Iron Co. is planning for the immediate construction of a new 1-story foundry on local site.

Pennsylvania

FRANKLIN—The Atlantic Refining Co., 3144 Passyunk Ave., Philadelphia, is said to have plans under way for the rebuilding of the portion of its local plant, operated under the name of the Eclipse Oil Works, recently destroyed by fire, with loss in excess of $90,000, including equipment.

PHILADELPHIA—The H. H. Barton & Son Co., 109 South 3rd St., manufacturer of abrasive papers and materials, will commence the immediate erection of a new building at its plant on Bleigh St., estimated to cost about $25,000. The construction contract has been let to the Roydhouse Arey Co., Fidelity Bldg.

HIGH SPIRE—The Keystone Carbonic Gas Co., Inc., manufacturer of commercial oxygen, hydrogen, etc., will commence the immediate erection of its proposed new local plant for the manufacture of carbonic gas, etc. The company recently acquired a local site.

Tennessee

GRAYSVILLE—The Dixie Coal, Lime & Clay Products Co. has plans under way for the construction of a local plant, comprising a number of 1-story buildings, for the manufacture of brick and other burned clay products. It will be equipped for initial output of about 100,000 bricks per day. O. E. Thomas is president.

Texas

ELECTRA—The Council will commence the immediate construction of a new water-purification plant at the municipal water works, with capacity of about 500 gal.

DALLAS—The Dallas Gas Co. has preliminary plans under way for extensions and improvements in its plant and system, to cost in excess of $300,000. Henry C. Morris is vice-president and general manager.

Virginia

WINCHESTER—The American Gas Improvement Co., 26 Cortlandt St., New York, has acquired the local plant of the Winchester Gas Co., and has plans under way for extensions and improvements. The capacity will be increased with the erection of a new unit on local property recently acquired.

West Virginia

HOOKERSVILLE—The Muddlaty Valley Clay Products Co., recently organized, will soon commence the construction of a new local plant for the manufacture of brick, tile and kindred burned clay products. The initial works will comprise two 1-story structures, each about 25x120 ft. Porter Herold is secretary.

Wisconsin

FORT ATKINSON—The Fort Atkinson Tanning Co. is considering preliminary plans

for the rebuilding of the portion of its leather plant, destroyed by fire, June 11, with loss estimated at close to $100,000, including equipment. The plant occupies about 4 acres of land and five buildings were destroyed.

MILWAUKEE—The Rundle Mfg. Co., 27th St. and Cleveland Ave., has commenced the construction of a new 1-story building, 60x200 ft., at its iron works, to be equipped as a foundry. It will cost about $50,000.

Wyoming

CASPER—The Texas Co., 17 Battery Place, New York, N. Y., is completing plans for the construction of its proposed new local oil refinery on tract of about 500 acres of land, and will commence construction at an early date. It is purposed to have the initial unit ready for operation late in the fall. The works will have a capacity for handling about 5,000 bbl. of crude oil per day, and will include complete byproducts departments for the recovery of gasolene, naphtha and other products.

Canada

NELSON, B. C.—The Consolidated Mining & Smelting Co. of Canada, operating large plants at Nelson and Trail, B. C., is completing plans for the construction of a new concentrating plant, estimated to cost in excess of $1,000,000, with machinery. A power plant will also be constructed. S. G. Blaylock is general manager.

MONTREAL, QUE.—The Dominion Oxygen Co., Ltd., has recently acquired the property of the National Electric Products Co., Ltd., manufacturer of similar commercial oxygen, etc., and has plans under way for plant enlargements and improvements. It is said that a number of branch works will be located in different important Canadian cities. The business of the acquired company will be merged with the Dominion organization.

Mexico

MEXICO CITY—The San Rafael Paper Co., operating a local mill, has plans nearing completion for the erection of a new plant at Merida, Yucatan, for the manufacture of pulp products under a special process. Leaves of the henequin plant will be used as a source of raw material.

New Companies

THE BETHEL TANNING Co., Bethel, Conn., has been incorporated with a capital of $50,000, to manufacture leather products. The incorporators are F. H. Judd, H. E. Mackenzie and David Lane, all of Bethel.

THE W. J. WIX & SONS Co., 104 Market St., Camden, N. J., has been incorporated with a capital of $50,000, to manufacture paints, varnishes, etc. The incorporators are W. J. Wix, Sr. and Jr., and J. C. Wix.

THE CRYSTAL & SCIENTIFIC GLASS PRODUCTS Co., New York, N. Y., care of T. F. Daniels, representative, South Orange, N. J., has been incorporated with a capital of $100,000, to manufacture special glassware specialties. The incorporators are F. and Z. Kafka, and G. C. Volz.

THE BI-CHEMICAL Co., Memphis, Tenn., has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. The incorporators are H. S. Austin, Karl Wood and R. W. Snell, all of Memphis.

THE AETNA ABRASIVE Co., 1462 West Ohio St., Chicago, Ill., has been incorporated with a capital of $5,000, to manufacture emery wheels and other abrasive products. The incorporators are Anton S. Lux, Frank Cass and John J. Leskee.

THE BOLIVAR FOUNDRY Co., Bolivar, N. Y., care of Bliss & Bliss, Bolivar, has been incorporated with a capital of $50,000, to manufacture iron, steel and other metal castings. The incorporators are W. A. Sherwood, H. J. McIntyre and W. J. Brennen, Bolivar.

THE NEW BEDFORD TILE PRODUCTS Co., New Bedford, Mass., has been incorporated with a capital of $100,000, to manufacture tile and other ceramic products. Elie Blanchette is president; Francois X. Girard, vice-president; and Ulric LeClair, 1020 South Water St., New Bedford, treasurer.

THE ATLASTA TIRE & RUBBER Co., care of Franklin L. Mettler, 832 Market St., Wilmington, Del., representative, has been incorporated under state laws with capital of $500,000, to manufacture tires and other rubber products.

THE LUCKERT-KLEB-GERARD MFG. Co., 61 Wheeler Point Road, Newark, N. J., has filed notice of organization to manufacture washing fluids and other chemical specialties. The company is headed by William Luckert, Louis Kleb and Nicholas Gerard.

THE OHIO REFRACTORIES Co., Portsmouth, O., has been incorporated with a capital of $100,000, to manufacture firebrick and other refractory products. The incorporators are M. K. Hitchcock and H. W. Heer, both of Portsmouth.

THE KEENE TANNING Co., Boston, Mass., has been chartered under state laws to manufacture leather products. Nathan Gans, 13 Lincoln St., Cambridge, Mass., is president and treasurer; Mahlon H. Anderson is vice-president.

THE MARINE RUBBER Co., care of the Delaware Registration Trust Co., 900 Market St., Wilmington, Del., representative, has been incorporated under state laws with a capital of $1,250,000, to manufacture special armored rubber products.

THE CHILDERS BROTHERS CHEMICAL Co., Lake Wales, Tex., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. Reuben R. Childers is president; George E. Childers, vice-president; and P. M. Childers, secretary, all of Lake Wales.

WILLIAM W. WOOD & Co., INC., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $750,000, to manufacture leather products.

THE WYOMISSING CEMENT PRODUCTS Co., North Wyomissing Heights, Wyomissing, Pa., has been incorporated with a capital of $10,000, to manufacture cement specialties. B. F. Willson, Wyomissing, is treasurer.

THE SUPERIOR OIL CORP., Nashville, Tenn., has been incorporated with a capital of $25,000, to manufacture petroleum products. The incorporators are H. B. Hammond, E. W. Turnley and C. M. Carroll, all of Nashville.

Industrial Developments

CERAMIC—The Pittsburg Clay Products Co., Pittsburgh, Pa., is operating at full capacity at its plants at Walkers' Mills and Beaver Falls, Pa., for the manufacture of face brick. The present output is running to 1,500,000 bricks per month, and it is expected to increase this production to about 2,000,000 bricks at an early date.

All face brick manufacturing plants in the Birmingham, Ala., district are operating on a full-time schedule. The orders taken in May are the largest for any month since the close of the war.

Sankey Brothers, Pittsburgh, Pa., manufacturers of brick, are running at a full-capacity schedule at their local plant, comprising 6 kilns, with average of 300,000 bricks to the kiln.

The Thomas Maddock's Sons Co., Trenton, N. J., manufacturer of sanitary ware, is operating on a full time, full-capacity schedule. Incoming orders are exceeding the output.

OIL—The Wortham Refining Co., Wortham, Tex., has placed its new refining plant in operation, recently completed, under a day and night schedule. The refinery will use crude oil from the Wortham, Currie and Mexia fields.

The Milliken Refining Co., St. Louis, Mo., has resumed operations at its oil refinery at Arkansas City, Kan., following a suspension for about a year past.

RUBBER—The Excel Rubber Co., Wadsworth, O., has been reorganized, following the termination of a receivership, and the plant placed in operation. It is proposed to develop a capacity output at once. The plant specializes in tires and belts, and has been closed for about 6 months past.

The Goodyear Tire & Rubber Co., Akron, O., has adopted an 8-hour shift at its plant, replacing a 10-hour day working basis, allowing employees the same wages for the shorter day. The plant is on a capacity basis.

The United States Rubber Co., New York, N. Y., is arranging for the resumption of operations at its Candee plant at New Haven, Conn., on July 5, following a suspension since May 1.

The plant of the Avalon Rubber Co., Barberton, O., has been sold by the receiver to a syndicate, recently formed, and will be used for another line of manufacture. Production of rubber will be carried out as a subsidiary feature of operations.

The Studebaker-Wulff Rubber Co., Marion, O., has adopted a night shift at its plant, in addition to regular day production. Incoming orders exceed the capacity of the plant.

IRON AND STEEL—The Thomas Furnace Co., Milwaukee, Wis., is planning to blow in its furnace for pig-iron production early in July.

The Donaldson Iron Co., Emaus, Pa., is making ready for operations at its No. 2 foundry, and will place the plant in service at an early date. With this unit on the production list, the company will be operating at full capacity.

The Reading Iron Co., Reading, Pa., has advanced the wages of puddlers at its Columbia, Pa., works from $6.50 to $7 a ton. The pay of laborers has also been increased.

The Petroleum Iron Works, Petroleum, Pa., is arranging to advance production about 20 per cent at its plant, following the booking of several large orders.

Following part-time operation for about a year past, the Buffalo Steel Co., Buffalo, N. Y., has resumed production on a full-capacity basis, with day and night working forces.

The Shelby Iron Co., Birmingham, Ala., has resumed operations at its Shelby, Ala., stack. The company is said to have booked a good volume of orders for its charcoal iron production.

The Minnesota Steel Co., Duluth, Minn., has increased production to a 60 per cent operating basis, and will add about 1,000 men to the working force at once.

The Carpenter Steel Co., Reading, Pa., has advanced the wages of laborers at its mills from 24 to 27 cents an hour. All other workers at the plant will also receive a proportionate increase, effective July 1.

The Guide Plate Bar Mills is planning to blow in another furnace at its Birmingham, Ala., works. The stack will be used for manganese production.

MISCELLANEOUS—The Golden Rod Mining & Smelting Co., Cardin, Okla., will resume operations at once at its No. 7 mill, following a shut-down for more than a year past. The mill is one of the largest concentrating plants in this section, with a rated capacity of about 1,000 tons a day.

The Cleveland Iron Co., Houghton, Mich., has resumed operations on a full-time basis at its iron-ore properties in this district, following a half-time operating schedule for the past year.

Leather tanneries throughout the country devoted to the production of upholstery leather are operating on a full-time basis, with heavy orders booked ahead.

The Corn Products Refining Co., New York, N. Y., has arranged for the resumption of operations at its Edgewater, N. J., refinery, following a suspension from last April. Other plants of the company are now running on a basis of about 65 per cent of capacity.

The Bastrop Pulp & Paper Co., Morehouse Parish, near Monroe, La., has commenced operations at its new local mill, following a curtailment for a number of months. It is proposed to develop capacity output at an early date.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold a summer excursion meeting to Rochester, Montreal, Ottawa, Kingston, Toronto, Hamilton, Niagara Falls and Buffalo, Aug. 13-19.

AMERICAN CHEMICAL SOCIETY will hold its fall meeting in Pittsburgh, Pa., Sept. 5 to 9.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 21, 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN SOCIETY FOR STEEL TREATING will hold its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN SOCIETY FOR TESTING MATERIALS is holding its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters are at the Chalfonte-Haddon Hall Hotel.

ANNUAL SAFETY CONGRESS OF THE NATIONAL SAFETY COUNCIL will be held in Detroit, Mich., Aug. 28-Sept. 2.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) will be held in New York Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY will meet at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.
